significant serum antibody titers obtained from hese children three, four, five, and six years after vaccination have been reported.[3]

Group B.—Group B consisted of children in an nstitution who received the SM N-90 type 1 chick embryo–adapted strain of poliovirus in 1954 and 1955.[4] All subjects showed excretion of virus. Persistence of antibody has been reported at one year nd at two and one-half years after vaccination.[5]

Group C.—Group C included normal infants less han 6 months old who were fed poliovirus in 1955-1957 by Koprowski and his colleagues.[6] The 13 nfants each received one or two of four different vaccine strains: the TN type 2 strain, the SM type 1 strain, the monkey kidney–adapted CHAT type 1 strain, or the similarly adapted Fox type 3 strain. Fecal excretion of poliovirus occurred after all feedings with the exception of one with the TN virus.

Administration of Virus.—The virus was administered by bottle or dropper as virus-containing fluid diluted in milk or a similar bland vehicle. Detailed data relative to administration of virus and clinical observations were reported previously.[7]

Laboratory Studies.—The tests for neutralizing antibodies reported here were performed with monkey kidney or HeLa cells by either one of two methods: the metabolic inhibition test [8] or the roller tube test proposed by Gard.[9] The serums from groups A and B were titrated by the metabolic inhibition test. In all tests the 1958 serums were paired with serums obtained in 1955 or 1956.

Serums from Group C before and up to seven months after vaccination were also tested by the metabolic inhibition test, while serums obtained from this group in 1958 were tested by the Gard technique. Paired specimens from group C, with one exception, could not be tested, because serums obtained prior to 1958 were unavailable. The single earlier serum which was available gave a titer in the 1958 Gard tests identical to that observed previously with the metabolic inhibition test. Isolation of virus from stools was performed in monkey kidney tissue culture, according to a method already described.[10]

Results

All 27 subjects have remained well, without apparent illness as a result of their exposure to attenuated poliovirus. The determinations of neutralizing antibody in these subjects as well as pertinent data relative to their vaccinations are given in tables 1 to 3.

Group A.—Approximately eight years after vaccination, all seven individuals in group A have type 2 antibody titers ranging from 1:16 to 1:256, with a median of 1:64, as shown in table 1. The current titers on the average are one twofold dilution less than those demonstrated approximately six years after vaccination. In comparison with type 2 antibody levels determined one to two months after feeding, the current titers show a decline averaging about three twofold dilutions. Also included in table 1 and discussed below is a type 2 feeding to a member of clinical Group B.

Group B.—As shown in table 2, group B demonstrates the persistence of antibodies to type 1 attenuated virus for four and one-half years. The serums obtained in 1958 had titers ranging from 1:16 to 1:512, with a median of 1:128. These le are below those determined approximately t one-half years postvaccination by about fold dilution, but on the average are equal to obtained one to three months after feeding. Sub SC, who was given SM type 1 and TN typ poliovirus simultaneously four and one-half yea prior to the 1958 tests, retained antibodies to both types (tables 1 and 2).

* Excretion not studied beyond this time.

Group C.—Fourteen feedings of attenuated poliovirus were given to the 13 infants in group C, as shown in table 3. Infant C2 was given separate feedings of SM and TN strains two months apart. The infants were vaccinated orally at 5 days to 6 months of age when moderate titers of transplacental serum antibody were present in all but one instance. Such antibody apparently exerted no inhibitory effect on the active response to alimentary multiplication of poliovirus, except that antibody response to vaccination had to be judged not only by a fourfold increase in titer but also by the persistence of significant antibody levels beyond the time when transplacental antibody would be expected to survive. The method of judging the expected decline of such passive antibody has been described elsewhere.[6b]

The SM strain was ingested by seven infants, all of whom have maintained high levels of antibody (1:256 to 1:1,024) 15 to 28 months after feeding. The CHAT strain was administered to two infants, both of whom continued to have type 1 antibodies, approximately one year later. The TN type 2 strain was given to three infants, all of whom had antibodies 21 to 25 months after feeding. One of the [illegible] however, retained a type 2 titer of only 1:6.

Two infants were bled 14 months after having received the type 3 Fox strain. While one of them (C37) retained type 3 antibody at a titer of >1:1,024, the other infant (C34) had no demonstrable antibody to type 3 virus even when undiluted serum was tested.

Infant C34 received $10^{5.5}$ TCD_{50} of Fox virus in December, 1956, when a titer of 1:64 of type 3 transplacental antibodies was present. Type 3 virus was isolated without difficulty from his feces on the 3rd, 7th, and 10th days postvaccination, but not on the 14th day. The type 3 antibody titer after feeding was 1:64 and 1:48 at 29 days and 56 days respectively. The titer thus remained stable for two months after vaccination instead of following the expected decline of passive antibodies. These data fulfill the criteria of a successful vaccination of infants as previously defined,[6b] but it must be noted that in the absence of definite evidence of an increase in antibody it is possible that in this subject a poor antigenic stimulus was produced originally.

Intestinal Resistance to Poliovirus Infection.—It was of obvious interest to determine whether intestinal resistance to poliovirus infection would remain after the loss of detectable antibodies in the serum of infant C34. Accordingly, 19 months after the original feeding in December, 1956, a second dose of $10^{5.5}$ TCD_{50} of Fox strain was given to infant C34. The results of the two feedings are compared in table 4. Type 3 virus was easily recovered from the stool after the first feeding by direct inoculation of a suspension into monkey kidney tissue culture, whereas after the second feeding similar direct inoculation of stool suspensions demonstrated only a trace of virus at 10 days after feeding. A blind passage of the tissue culture fluid from the tubes inoculated with stool suspension from this second feeding demonstrated type 3 virus on the 7th, 10th, and 14th days after feeding. The type 3 antibody titer, which was undetectable on the day of second feeding, rose to 1:64 one month later.

† In TN feedings, 50% mouse paralytic dose.
‡ Infant C2 received both SM and TN.
§ Antibody detectable at 1:4, but serum not sufficient for titration.

Factors Related to Serologic Response.—In group C (table 3) neither the young age of the infants nor their possession of transplacental antibodies had any discernible effects on antibody levels after vaccination. For example, infant C26 was given the SM strain at 5 days of age when his type 1 titer was 1:256. He excreted poliovirus for 35 days after feeding and his type 1 titer rose to 1:256 at 3 months of age after an earlier drop to 1:64 at one month of age. Twenty months after vaccination a titer of 1:512 was present.

Natural Booster Infection.—The possibility was considered that booster infection by natural wild poliovirus may have contributed to the persistence of antibodies. In order to determine the likelihood of natural homotypic infection the heterotypic antibody titers (to poliomyelitis types not fed) were studied in the most recent specimen from each subject. The results, presented in table 5, show that heterotypic antibody was absent in the majority of tests. In about 30% of tests, i. e., 33% for groups A and B and 24% for group C, such antibody had been acquired since vaccination.

Comment

The results in general support the concept that seroimmunity after live-virus vaccination is of long duration. The seven children in group A who were vaccinated with TN strain in 1950 or 1951 have been followed longer than any other recipients of poliomyelitis vaccine, either of living or inactivated virus origin. All have type 2 antibodies currently. The seven children in group B who were vaccinated with the SM type 1 strain four to four and one-half years before also retained antibody.

Group C is particularly interesting in that all but one of the 13 infants had transplacental antibody at the time of live virus feeding. Homotypic antibodies were present (table 3) one to two years after 13 of the 14 vaccinations in this group. One infant had lost all detectable type 3 antibody 14 months after feeding. This same child was demonstrated to have a relative "intestinal resistance" to type 3 poliovirus as judged by the low level of virus excretion which occurred after refeeding with Fox strain 19 months after its first administration (table 4). Resistance to intestinal reinfection has been demonstrated by Fox, Sabin, Koprowski, and Horstmann [11] in subjects immunized by both natural and attenuated polioviruses. In the case presented in this paper, intestinal resistance seemed to be independent of the presence of serum antibody.

It is possible that booster infection occurring in nature may have contributed to the maintenance of seroimmunity to the types fed in some of the children. The probability of homotypic natural infection was calculated to be roughly 30%, based on the percentage of tests for heterotypic poliomyelitis antibodies which were positive.

Another method of detecting natural infection is simply by retrospective analysis of antibody titers during the years after vaccination, some of which have been reported previously.[3] In four subjects, one in group A and three in group B, fourfold or greater increases in homotypic antibody titer have occurred since the original response to vaccination. Subject 8 in group A had an increase of type 2 titer from 1:24 at 54 months after vaccination to 1:362 at 71 months. In group B, the type 1 antibody of subjects SC, JC, and Ge changed at 9 to 15 months after vaccination from 1:16, 1:16, and 1:712, respectively, to 1:256, 1:1,024, and 1:4,096 on the next determination. The first of the two specimens from each child was obtained in May, 1955. The second serum specimen was taken in September, 1955, from two of the children (JC and Ge) and in December, 1956, from the third (SC). Since SC is a sibling of JC, and Ge lives in the same cottage, it is possible that a silent epidemic of type 1 poliomyelitis infection occurred in the institution during the summer of 1955.

Despite the question of natural booster infection, it is clear from these results that seroimmunity and intestinal immunity to poliovirus last for years after live-virus vaccination. The median duration of antibodies has yet to be determined but, on the basis of the present study, exceeds eight years. Intestinal resistance to poliovirus has been demonstrated in [illegible] were [illegible] one case for at [illegible] 19 months after vaccination and may [illegible] be a more important criterion of immunity [illegible] than the presence of circulating antibodies [illegible]

In an isolated group of Eski[illegible] antibodies and associates,[1a] t[illegible] who were over 30 years were found [illegible] The data suggested that these antibodies had persisted approximately 35 years in the absence

[illegible]adiol, [illegible] midcycle [illegible] normal men- [illegible]rage today of ov[illegible] been perfo[illegible] of reinfection. This observation lends support to the theory that seroimmunity will persist indefinitely in most subjects infected with living virus and, coupled with the demonstration that vaccination can be successfully performed in early infancy, gives cause for optimism concerning the usefulness of living attenuated viruses as immunizing agents against poliomyelitis.

Summary

Type 2 poliomyelitis antibody was present in all of seven children approximately eight years after administration of the TN strain of living attenuated poliovirus. Type 1 poliomyelitis antibody was present in all of seven children approximately four years after administration of the SM strain of living attenuated poliovirus. Of 13 infants under 6 months of age at vaccination, 12 retained homotypic antibodies one to two years after feeding of the SM (type 1), CHAT (type 1), TN (type 2), or Fox (type 3) attenuated strains. The only child who no longer had demonstrable antibody to the type originally given was shown to be relatively insusceptible to intestinal reinfection by homotypic virus.

36th and Spruce streets (4) (Dr. Plotkin).

Barbara Cohen gave technical assistance for this study. Dr. Agnes Flack, Clinton State Farms, New Jersey, and Miss Dorothy Mooreby, New Jersey State Board of Child Welfare, assisted in making available the infants vaccinated in this study.

This work was supported in part by a grant from the National Institutes of Health, U. S. Public Health Service.

TRANSPLANTATION OF BONE.—In recent years attention has been centered on transplants or grafts of osseous tissue, largely in connection with the healing of fractures or the filling in of defects in bone structure. There is now general agreement that transplants of fresh autogenous cancellous bone or of bone marrow may survive in the host bed and produce new bone. There is less evidence for the survival and growth of transplants of homogenous bone and little or none for the survival of heterogenous grafts. It is recognized, however, that implants of frozen-, devitalized, or preserved heterogenous bone may lead to production of new bone in the host bed, by induction. Similar results are reported for implants of the decalcified bone and of bone mineral, prepared by removal of organic matter by solution in ethylene diamine.—Franklin C. McLean and Ann M. Budy, Connective and Supporting Tissues: Bone, *Annual Review of Physiology*, vol. 21, 1959.

SIMPLE CHEMICAL METHOD FOR THE DETERMINATION OF OVULATION TIME IN WOMEN

Manessch G. Sevag, Ph.D.
and
Sabin W. Colton, M.D., Philadelphia

The method here proposed for determining ovulation time requires that urine samples be collected nightly between 11 p. m. and 7 a. m. for from five to seven successive nights, beginning with the sixth or seventh day after midnight of the day the first menstrual bleeding occurs. The samples are tested by a special reagent for the presence of chemical substances as yet not fully identified; they give a blue color suitable for colorimetry. The color-yielding substance is a component of a complex containing a derivative of folic acid. Graphing the intensity of the color day by day yields a curve with a characteristic peak; the terminal low value, if it is on either the fifth or sixth day of the pattern, represents the day of ovulation. This hypothesis was tested by applying it to 227 cycles in which conception occurred by isolated coitus or husband or donor insemination. Among a total of 227 pregnancies there were 125 normal conceptions with full-term deliveries resulting from homologous or donor inseminations that afforded a basis for quantitative description of the ovulation pattern.

Various attempts have been made in the past to develop a simple, clinically applicable chemical method for the determination of ovulation time. None of these attempts has been found satisfactory. We report here a simple chemical procedure. The test, in its initial trial period, was compared with the Farris test (for hyperemia in the rat),[1] but no correlation was found. The new test has been applied independently of the rat test with gratifying results.

The test can be performed in any laboratory or medical office by a technician or nurse. One-tenth of a milliliter of daily urine is sufficient for a single test. The urine specimens of as many as 10 patients can be analyzed within an hour by an experienced person. The test has proved particularly useful in determining the ovulation time of patients with infertility problems. It is based on the measurement of the intensities of blue color developed in reactions between specific reagents and chemical entities produced in varying amounts by follicles and/or other organs believed to be stimulated or depressed by gonadotropic hormones during the ovulation cycle. Some information about the possible nature of the chemical entities responsible for the test results has already been obtained, but the discussion of their nature must wait for their final identification as the agents directly responsible for the results.

Procedure

Collection of Urine.—During the collection of urine for this test the patient should avoid drinking any kind of liquid—water, liquor, juices, or soda—and taking any kind of drug after 8 p. m. The urine voided between 8 p. m. and 11 p. m. should not be collected. The patient should collect all her urine nightly between 11 p. m. and 7 a. m. in individual clean, dry bottles and store it in a refrigerator after marking the date on each bottle. In this manner, urine is collected for from five to seven successive nights, beginning with the sixth or seventh d[illegible] after midnight of the day the first menstrual [illegible]ing occurred. From each of the collect[illegible] specimens, about 1 fl. oz. (30 ml.) is tr[illegible] individual clean, dry small bott[illegible] capped, and all the samples [illegible] tha-day for analysis. All the [illegible]nts the should be labeled a[illegible] throughout [illegible] two consecu- [illegible] rch, 1958) a single

of collection, and cycle day. The bottles should be washed with distilled water (iron rust from faucets should be eliminated during washing).

Analysis of Urine Specimens.—Step 1: [illegible] measurement bottles should be invert[illegible] times for u[illegible]n dispersion of the [illegible] sed for 5- [illegible]adiol, ure 0.1 [illegible] rine from each [illegible] midcycle cu[illegible] et of 0.1-or-[illegible] taken [illegible] normal men- [illegible] labeled [illegible] of ovula[illegible]n [illegible] color[illegible] been performed.

[illegible] the series were due to coitus or ended [illegible] miscarriages. Miscarriages are likewise excluded for the reason that it is not clear whether they are due to a too early or too late insemination or to the physiological condition of the subject or the ovum at the time of insemination.

As mentioned above, 53.6% of conceptions occurred according to the five-day pattern of the ovulation cycle and 36.0% according to the six-day pattern. That is, 89.6% of the conceptions occurred

These reagents can be measured with an ordinary graduated serologic pipet. Wait 10 minutes for the maximum development of blue color before diluting to the 10-ml. mark with distilled water, then mix the contents by inverting the tube with a clean thumb as stopper. Read the intensity of color in a Klett-Summerson colorimeter with filter 560.

Chemicals used for the preparation of reagent 3 must be of high purity. Into a 1.5-or-2-liter flask with ground glass joint introduce 100 Gm. of sodium tungstate ($Na_2WO_4.2H_2O$), 25 Gm. of sodium molybdate ($Na_2MoO_4.2H_2O$), 700 ml. of distilled water, 50 ml. of 85% orthophosphoric acid (H_3PO_4) solution, and 100 ml. of concentrated hydrochloric acid. After attaching a ground glass joint condenser reflux the contents gently for 10 hours. Then add 150 Gm. of lithium sulfate (Li_2SO_4), 50 ml. of distilled water, and a few drops of liquid bromine. Boil under a hood without condenser for 15 minutes to remove excess bromine. After cooling, dilute to 1 liter and filter through good quality paper into a thoroughly cleaned brown glass bottle or bottle adapted for plastic screw cap. The reagent should be stored in the dark and kept away from reducing agents. Before use, one part by volume of this reagent should be diluted with two parts of dis-
strable water in a clean cylinder and stored for daily
diluted serum ss-stoppered or screw-capped brown

almost invariably occurred the fifth, sixth, or seventh day after the initial low point of the patterns. Considering the random nature of the chemical studies, it appeared significant that a conception rarely occurred on other days than these (table 1). Also, these patients were not forced into a formula which might allow conception by random chance; we are dealing with normal physiological variation as well as the human element in the urine collection.

These conceptions were achieved by isolated coitus, single insemination from husband, or single therapeutic insemination from donor. Primary weight was given to conceptions by therapeutic donor insemination with normally developing pregnancies or normal full-term deliveries. Of the 78 pregnancies used in the initial standardization of the chemical test 22 were in this category.

With the pattern established, the chemical test alone was applied to patients with established fertility problems in an attempt to achieve conception. Also, where the chemical tests were run parallel to the rat tests, if the rat test results appeared erratic or atypical the chemical tests were used as a guide for planned coitus or insemination. Further refinements of interpretation were added as the number of pregnancies accumulated.

Ovulation time was evaluated according to a pattern which is easily recognized by looking over the colorimetric readings of the urine samples from successive cycle days. This pattern extends principally over five or six cycle days. The pattern of the ovulation cycle begins with the lowest colorimetric reading, followed by a gradual rise to a peak, followed by an abrupt, gentle, or gradual drop in the colorimetric readings. This terminal low value, if it is on either the fifth or sixth day of the pattern, represents the day of ovulation. The pattern has the appearance of a triangle, the angle on the left side corresponding to the cycle day of the beginning of the pattern, the vertex to the cycle day of the peak of the pattern, and the angle on the right of the triangle to the cycle day of ovulation. Several representative examples from over 200 pregnancies are given in table 2.

Results

Chemical tests were performed during the cycle of ovulation in 227 cases. Of these 112 conceptions were achieved after the use of the chemical test alone for the selection of the attempt at conception, and 37 conceptions in cases where the rat test was performed but the day of conception was selected from the chemical studies, for a total of 149 concep-
Of the 149 conceptions 33 were from single
eminations, with pregnancy either develop-
or having terminated normally. For
rage number of single donor in-
conception was 2.02, with
rst month of treatment.

This compares favorably with the results achieved by other workers [3] relying on three donor inseminations on alternate days.

It should be pointed out that, from those who are eventually successful, the proportion of those who conceive in the first month is considered to be the most useful measure of insemination efficiency. In the group compared by Potter [3] the proportion of first-month pregnancies varied between 31 and 46% as against 54.5% in our series on the basis of a single insemination. Even in the most successful of the series reported by Potter, basal body temperature readings and occasional vaginal smears were employed. In this same group of 33 patients 6.1% conceived on the fourth day, 57.6% on the fifth day, 33.3% on the sixth day, and 3.0% on the seventh day from the initial low point of the chemical pattern. These values are comparable to the following percentages of conceptions: From 125 patients who conceived 4.0% had a four-day pattern length; 53.6%, five-day; 36.0%, six-day; and 6.4%, seven-day.

† Beginning of ovulation pattern.

‡ Peak days.

§ Ovulation day for insemination or coitus.

‖ Inseminations were on 5th and 6th day, in accordance with established patterns, even though 5th and 6th day values occasionally were slightly higher than ones immediately preceding. It is possible that more uniform and precise patterns might be obtained if, instead of single r samples collected within period 11 p. m. t within each period were kept and analyze re elaborate procedure might result in obtaining sharper initial low points, pattern peaks, and last ovulation day within each pattern. Theoretically and clinically such a procedure might be desirable.

Two patients who required pelvic surgery for bilateral tubal obstruction had laparotomies in conjunction with the chemical test. In one patient, whose operation was performed on the predicted day of ovulation, a recently ruptured Graafian follicle was observed; in the other, whose operation was performed the day after the selected day of ovulation, a recently organized corpus haemorrhagicum was observed. The figure represents the chemical values for the same patient throughout the whole cycle from cycle day six for two consecutive cycles. In the first month (March, 1958) a single donor insemination was performed unsuccessfully. In the second month (April, 1958) the procedure was successful. The fluctuations in the chemical values in the two cycles are comparable to the higher values achieved in both instances during the preconception period. It should also be noted that the insemination was performed on the fourth day in the unsuccessful cycle, but on the corresponding fifth day in the successful cycle.

From the group total of 227 pregnancies 125 normal conceptions with full-term deliveries resulting from homologous and donor inseminations were used as a basis for the following calculations. Pregnancies due to coitus are not included for the reason that the exact day of coitus responsible for conception may be uncertain. The remaining pregnancies in the series were due to coitus or ended as miscarriages. Miscarriages are likewise excluded for the reason that it is not clear whether they are due to a too early or too late insemination or to the physiological condition of the subject or the ovum at the time of insemination.

As mentioned above, 53.6% of conceptions occurred according to the five-day pattern of the ovulation cycle and 36.0% according to the six-day pattern. That is, 89.6% of the conceptions occurred according to five-day and six-day patterns. The remaining 10.4% occurred according to four-day and seven-day patterns. These are borderline patterns, and it may eventually be possible to group them with the others. These patterns are consistent *with the known period of stimulation and maturation* of the Graafian follicle. If the distribution of conceptions on cycle days is determined, it will be observed (table 1) that 79.2% of conceptions occurred on cycle days 11 to 15, according to five-day and six-day ovulation patterns.

The results in table 3 show that in 89.6% of conceptions the observed peaks fell on the second, third, and fourth day of the ovulation patterns. Of these conceptions 40.8% occurred in patterns having the peak on the third day. Of the 26 conceptions occurring in patients whose patterns had second-day peaks, 65.4% were in patients with five-day ovulation patterns; 76.0% of 50 patients who conceived whose patterns had third-day peaks had five-day patterns; and only 25.7 of 35 patients who conceived who had their peaks on the fourth day had five-day cycles. From the standpoint of the mechanism and physiology of ovulation these differences are noteworthy.

If we analyze the results in a slightly different

en cycl
The variation of ulation Tom the second to the fourth day brings out a new phenomenon which may mean either that certain follicular systems are more reactive to the stimulating agents or th the quantities of these agents are produced in differe amounts in different ovulatory systems. The question of whether or not the relation of peaks to patterns varies from month to month in a given subject remains to be determined; however, in an individual patient in successive months the patterns are, in general, either consistently uniform or consistently irregular.

On the basis of the above-discussed results, the following considerations are evident: 1. Irrespective of the variation of the day, the peaks following the low point are the essential parts for the determination of the ovulation patterns and thereby the *predicted day of ovulation.* 2. *Irrespective of the variation* of the days on which the peaks were observed, 90% of conceptions occurred according to five-day and six-day long ovulation patterns. 3. Linked with 1 and 2 is the fact that 96.2% of conceptions occurred in patients with patterns having peaks on the second, third, and fourth days, on cycle days 10 to 15. Of these conceptions 50% occurred on cycle days 12 and 13.

Comment

The basic question in regard to the nature of the substances responsible for the results of the chemical test, particularly those underlying the occurrence of peaks during the ovulation cycle, cannot at present be answered. Preliminary tests show that the treatment of urine samples with weak acids and/or weak alkali with or without heating does not affect the test results. Chromatographic studies likewise show that none of the amino acids is responsible for the results. The presence of a certain class of substances collectively or individually responsible can, however, be conjectured. Of this class the flavonoids in urine need to be considered. They are biologically active substances which are invariably taken into the system in the form of seeds, vegetables, and fruits and are encountered in urine in their modified or original forms. A number of these substances have been estimated as to their potency for color development (table 5). Whatever may be the nature of the urinary substances responsible for the color developed in 0.1 ml. of urine, during the ovulation cycle there is a definite increase in colorimetric readings which is responsible for the critical peaks in the chemical patterns.

the sulfhydryl group, choline acetylase, hyaluronidase, oxidation of ascorbic acid and epinephrine histidine decarboxylase, and release of histamine; they interact with different metabolites and enzyme systems linked with the regulation of capillary permeability by reducing fragility; and they act synergistically in the body with ascorbic acid. Other participants in this symposium reported that the flavonoid quercetin regulates the sexual process of the unicellular alga Chlamydomonas eugametos. l-Phenylalanine, 3,4-dihydroxyphenylalanine (dopa), meso-inositol, and 3,4-dihydroxycinnamic and 3,4-dihydroxyphenylpropionic acids function as precursors for the formation of quercetin. The naturally occurring isoflavonoids are estrogenic. In plasma vitamin C deficiency associated with decidual hemorrhage and spontaneous abortion a fruit diet rich in vitamin C and hesperidine has been stated to exercise a therapeutic effect, and a combination of vitamin C and flavonoids has been used in treating impaired capillary functions and capillary bleeding.

It has been reported that urine of 13 of 16 normal women showed the highest vitamin C level on the 12th to 18th days of the menstrual cycle, and the day of ovulation was denoted by an 80 to 100% decrease in the vitamin C content.[6] A relationship between the elimination of ascorbic acid in the urine and the basal temperature curve has been reported in a series of 32 women.[7] In 62.5% of the series the decrease in the excretion of vitamin C coincided with the characteristic drop in basal temperature. The menstrual period was characterized by poor elimination of vitamin C. In this connection it may be added that the lowering of ascorbic acid by norepinephrine is five times that by epinephrine.[8]

Epinephrine and a number of derivatives and precursors (table 5) are reported to be present in urine in appreciable amounts. 3-Methoxy-4-hydroxyphenylacetic acid[9] and 3-methoxy-4-hydroxy-D-mandelic acid[10] are major metabolites of norepinephrine and epinephrine. Dopa, dopamine, and 3,4-dihydroxyphenylpyruvic acid are reported to be the precursors of epinephrine.

In relation to ovulation time the interrelationship of platelets and epinephrine is noteworthy. It is reported[11] that the platelets consistently reached their highest levels during ovulation, as determined by basal body temperature graphs. In midcycle the levels of platelet counts usually rose suddenly and dramatically within 24 hours to reach the highest point during the entire cycle. Within another 24 hours the platelets returned to their previous levels and remained constant or decreased gradually until the onset of the next menstrual period. It was reported that the thermal shift coincided with that of the platelets. In view of the accepted facts that the basal temperature shift from the low to the high phase is indicative of ovulation and that ovulation may immediately precede or follow the temperature shift, Pepper[11] suggested that the platelet peak may be coincidental with ovulation in the vast majority of menstrual cycles.

Blood platelets are carriers of epinephrine and norepinephrine,[12] and they harbor 5-hydroxytryptamine.[13] It has also been reported that plasma epinephrine undergoes rapid and extensive changes in response to the injection of various hormones and drugs.[12] It was found that the injection of 20 units of ACTH daily foı three days in four normal subjects resulted in a decrease in the excretion of norepinephrine but little or no change in excretion of epinephrine.[14]

* Klett-Summerson colorimetric readings, filter no. 560.

† 5% sodium carbonate solution tested after 48 hours at room perature.

A team of investigators[15] at the Univer The Edinburgh, measuring combined estrone, estradiol, and estriol excretion, reported finding a midcycle ovulatory peak in eight women with normal menstrual periods in whom the average total estrogen excretion was 56 mcg. per 24 hours. In view of the high colorigenicity (the property of a substance to yield a color in a reaction system) of epinephrine and related substances, and despite the low colorigenicity of estrone (table 5), the interaction of hormones and vitamins such as epinephrine, gonadotropic hormones, vitamin C, and flavonoids is evident.

Eventually it may be possible to correlate the sharp increases in urinary estrogen levels, the platelet peaks, and the known basal temperature shifts with the second, third, and fourth day peaks observed by our chemical test in establishing ovulation cycle patterns for the further understanding of the physiology and chemistry of the ovulation cycle. Epinephrine and related substances may be responsible for the peaks we have observed and also may account for the platelet peaks and increases in estrogen output.

From the standpoint of characterizing the mechanism of the physiology of ovulation and reproduction we feel that we have a new simple tool to determine the nature of factors responsible for the chemical ovulation patterns. The following observations have recently been made: Folic acid derivatives present in 1 ml. of urine yielded a pattern paralleling the chemical ovulation pattern. Chlorides and para-aminobenzoic acid in these urine specimens have no correlation to the above patterns. Chromatograms of 0.1-ml. urine specimens show one main spot and at least two minor spots. In butanol–acetic acid–water solvent (50:25:25 by volume) the main spot has Rf value of 0.33, and one of the minor spots has Rf value of 0.86. The latter gives a positive ninhydrin reaction. In isopropanol–acetic acid–water (25:1:74 by volume) solvent the Rf of the main spot is 0.57. This substance has 284 mμ λ maximum and 254 mμ λ minimum. A similar compound is present in the male urine. The colorogenic main spots of both the male and female urine specimens have citrovorum factor activity. It would seem that the main spots are large molecules composed of a colorogenic substance, citrovorum factor, and possibly of other unknown substances. The hormonal, enzymatic, and chemical natures of these substances are being investigated.

We feel that the chemical ovulation patterns are completed with the beginnings of the chemical patterns corresponding to the ovulatory stimulation of follicles and the rupture of the Graafian follicles with the liberation of ova. Characterization of entities in the urine during this period would be expected to throw new light on the reproductive mechanism.

Summary

A simple chemical test based on color development, applied to first morning urine specimens for the prediction of the day of ovulation, was applied to 227 cycles in which conceptions occurred by isolated coitus or husband or donor insemination. In most instances a uniform, triangular five, six, or seven day pattern of chemical values afforded a basis for prediction of the day of conception. Of the 227 conceptions 149 were based solely on the chemical test predictions. Of patients who had single donor inseminations 54.5% conceived the first month of treatment. It took an average of 2.0 cycles for conceptions to be achieved in this group.

Thirty substances, hormones, vitamins, and chemicals, are analyzed by this test for their colorigenicity. Several of these may be factors responsible for the color developed in 0.1-ml. urine samples. Attention is called to the possible role of catecholamines and, particularly, epinephrine, norepinephrine, and related substances. There appears to be a close relationship among the peaks of platelet counts, estrogen output, and the colorimetric values which were observed in the present work, suggesting that in time a common causal factor may be found.

1930 Chestnut St. (3) (Dr. Colton).

George B. Koelle, M.D., Ph.D., Professor of Pharmacology and Dean of the Graduate School of Medicine, University of Pennsylvania, supplied many of the phenylalkylamines and indolalkylamines used in this study. Gustav J. Martin, Sc.D., Director of Research, National Drug Co. Research Laboratories, Philadelphia, contributed flavonoids; Abbott Laboratories, North Chicago, Ill., contributed the sample of piperazine estrone sulfate; and Smith, Kline & French Laboratories, Philadelphia, contributed the samples of thyroxin and sodium liothyronine.

CRITICAL EVALUATION OF THE PSORALENS

Harry Pariser, M.D., D.Sc., Norfolk, Va.

Opinions as to the usefulness of the psoralen group of drugs in treating vitiligo were obtained by questionnaire from 100 dermatologists in various parts of the world. Two dermatologists were enthusiastic about the systemic use of the psoralens, eight were vehement in their condemnation, and most considered the results poor. Systemic use of the psoralens caused a wide variety of disagreeable signs and symptoms such as nausea, vomiting, gastric burning, dermatitis, rectal bleeding, albuminuria, and jaundice. Animal experiments demonstrated eye damage (cataracts) and the development of tumors through probable photosensitizing factors. The psoralens are presumed to enhance tanning and increase resistance to sunburn. The use of drugs of such potential toxicity for what is primarily a cosmetic problem should be deplored. In those instances in which tanning is medically desirable, the results have been equivocal.

The Egyptians, since the 13th century, have been using for medical purposes the powdered fruit of the *Ammi majus Linn*, a plant found abundantly in the Nile Valley. Recently this plant has been identified as a member of the parsley family and is known in the United States as bishop's-weed, which grows in the western part of the country. Reputedly, use of these agents, the psoralens, resulted in pigmentation of vitiliginous skin, but side-reactions caused were nausea, vomiting, diarrhea, severe vesiculation, exfoliative dermatitis, and even coma. For a condition such as vitiligo, which was previously regarded as having no treatment of even minor helpfulness, such reports deserve investigation. Who knows but that from the ancient lore, whence came ephedrine, digitalis, and Rauwolfia, another drug may be emerging. The preparations, originally designated as ammoidin, ammidin, and majudin, were found to be identical, respectively, to the known compounds xanthotoxin, imperatorin, and bergapten [1] and are now designated as 8-methoxypsoralen, 8-isoamylenepsoralen, and 5-methoxypsoralen. The first of these is regarded as the most active,[2] the second is practically inactive, and the third is only moderately active photodynamically.[3] The generic name methoxsalen has been given to 8-methoxypsoralen.

The first scientific report on this subject, by el Mofty, appeared in the *Journal of the Royal Egyptian Medical Association* in 1948.[4] He republished his findings in English in the *British Journal of Dermatology*.[5] The psoralens were used orally, locally, and intradermally. A dose of ultraviolet light was given once or twice a week after the lesions were painted with solutions that were of varying concentrations. Response to treatment was noted in about three to six weeks and consisted of tiny hyperpigmented follicular spots and hyperpigmented growth from the edges. El Mofty stated that 5 of 15 patients were considered cured, 5 achieved a good response and 1 a partial response, and there were 4 failures. Five whose conditions were resistant to oral treatment showed response to intradermal therapy but none completely so. Of these, two showed response only after intradermal injections were supplemented by oral medication. Control areas treated with topical medication alone, ultraviolet light alone, or intradermal injections alone did not respond. Therefore, he concluded that results depend on a source of light changing the compound into a form which stimulates melanogenesis. Kanoff[6] subsequently confirmed this. Sidi,[7] in an attempt to evaluate intradermal therapy, found this mode of treatment very painful as well as ineffective in three of four patients.

Since the original report, many others have appeared. All the authors have used essentially the same over-all technique or attempted to evaluate one phase of the treatment. For example, some used varying doses of orally given medicaments, others varied the concentration of locally applied medicaments, and still others combined the local and systemic medication.

Although the classic approach to the discussion of a problem is a brief review of each article on the subject, I prefer to depart from this method and to discuss and, to some extent, evaluate the techniques used as reported in the literature. The discussion will be divided into evaluation of local treatment, systemic treatment, and combined treatment. In both local and systemic treatment, including "paired comparison," it is generally agreed that ultraviolet light (preferably sunlight) enhances the effect. The effective wave lengths appear to be between 2,500 A and 4,077 A.

Local Treatment

Those investigators using local treatment concerned themselves with varying the vehicle (cream or solution), the composition of the diluent, the concentration and composition of active ingredients, the frequency of application, the time interval between local applications of the medicament, and the use of subsequent irradiation. From this emerges a fairly standardized technique which consists of

---

Read at the McGuire Memorial Lecture Series, Medical College of Virginia, Richmond, Nov. 13, 1958.

first treating with a low concentration of the medicament (about 0.1%) and gradually increasing the concentration to tolerance point (usually not above 1%). The vehicle selected appears to make very little difference provided the active medicament is dissolved or uniformly suspended. The time interval of two to four hours between applications of the solution and the use of daily irradiation appears to give the best results. Some authors feel that the medicament should be washed off before ultraviolet irradiation is given, since the drug tends to filter out some of the rays. Exposure to ultraviolet light or sunlight must be as short as 5 to 10 seconds in the early stages of treatment and gradually increased in relation to tolerance, probably never much over 20 to 30 minutes. Uncontrolled sun exposure almost always results in severe reaction.

A limiting factor in the wide acceptance of this mode of therapy is a rather severe local toxic reaction which appears in practically all cases. This consists of swelling, blistering, oozing, and considerable associated pain, followed by marked scaling, pruritus, and hyperpigmentation. Occasionally, eczematization, ulceration, and even exfoliative dermatitis are also noted. Increased sensitivity to sunlight may persist for months without further application of 8-methoxypsoralen.[3] These reactions are often severe enough to incapacitate the patient completely for several days, particularly if the ultraviolet light dosage is uncontrolled.

Most authors agree that the degree of repigmentation is not dependent on the degree of reaction, since repigmentation has occurred with no reaction and has, at times, failed to appear after severe reaction. However, it is true that most patients who achieve repigmentation do so after severe reaction.

Systemic Treatment

The evaluation of systemic administration of the psoralens was concerned primarily with using varying percentages of the different psoralens and experimenting with varying doses. At present, the technique, after considerable trial and error, consists in administering 10 mg. orally three times daily or 20 mg. once daily. This is followed in two to four hours by daily use of ultraviolet light (sunlight if possible). Intervals of rest from the drug are advised by some. Again, most authors note that repigmentation is independent of the severity of the reaction. It is difficult to determine from the literature whether 8-methoxypsoralen alone is superior to combinations of drugs; certainly the effect is not statistically apparent. Sunlight exposure should be short, that is, 5 to 10 seconds at first with gradual increase to maximum tolerance. A protective cream should be used between ultraviolet exposures.

In the literature many[8] claim the superiority of local treatment over systemic therapy; others[9] report equally satisfactory results from systemic treatment alone. However, the marked reaction to be anticipated from local therapy eliminated to a large extent its wide acceptance except in use for small patches of vitiligo. At present the place of the psoralens in medical therapy largely depends on the effectiveness of systemic use combined with sunlight or ultraviolet light and on toxicity after systemic administration.

Evaluation of Treatment

Before evaluating any drug, one should know certain variables concerning the natural course of the disease for which it is used. Apparently there is no report concerning the frequency of spontaneous repigmentation in vitiligo, although I have noted it and it has been reported by others. I have also, on occasion, been able to note repigmentation after frequent local application of concentrated phenol to small patches of vitiligo or after the use of oil of bergamot followed by ultraviolet light, both procedures considerably less painful and less toxic than the use of 8-methoxypsoralen. It is not at this time evident whether there was a cause and effect in these procedures or whether spontaneous repigmentation occurred in these patients during the observational period of 8 to 15 months.

It is well known that hyperpigmentation often and depigmentation occasionally occur after a marked degree of inflammatory reaction in Negroes. Most authors using the psoralens noted that Negroes tend to respond more readily than Caucasians and children better than adults. Lesions of the face and trunk respond better than those of the mucous membrane, hands, and feet. Repigmentation practically never occurs in the genitalia. Lesions of recent origin respond better than those of long duration.

The over-all results obtained by authors varied so widely that evaluation is quite difficult. For example, in THE JOURNAL,[10] in November, 1955, is a statement that satisfactory results can be obtained in 30 to 40% of patients treated orally, 50 to 60% of those treated topically, and 80 to 95% of those treated by the combined methods. This observation was based on 200 recorded cases to date in the American and Egyptian literature. Sidi[7] reported significant repigmentation in 84% of 106 patients given oral treatment. Elliott,[11] in 1956, noted that 18 of 22 patients showed significant repigmentation by combined treatment and that the 4 who showed poor response had failed to cooperate properly. Levai[12] indicated that 54% of his patients who stated they had had previous skin trouble at the sites of their vitiligo and 68% without such difficulty achieved 95 to 100% repigmentation. Srivastava,[13] as well as Kelly,[14] indicated that 25% of their patients showed complete repigmentation, the former using combined and the latter local treatment. On the other hand, Sulzberger and Lerner,[15] in a recent article, reported that only 14% of patients achieved a satisfactory repigmentation, and Kanoff,[16] working on a large number of cases at the Skin and Cancer Hospital, as well as in his private practice, wrote that only 10% obtained a cosmetically acceptable repigmentation.

One must realize that the definition of satisfactory is relative, since some have regarded as satisfactory any repigmentation and others only significant [illegible] from a cosmetic point of view, a small or even a significant amount of repigmentation often does not enhance the appearance. In my own series of 17 patients treated orally with doses of 10 mg. three times daily followed by weekly exposure to ultraviolet light, no patient achieved more than 50% repigmentation and, in most instances, less than this or nothing. Topical applications were abandoned after severe reaction in three patients without any significant response in any of them.

To evaluate this wide discrepancy in results, I sent a questionnaire to 125 dermatologists. A total of 100 replies were received from these men, who practiced in both small and large communities throughout the world; they varied from professors of medical schools to those with no academic connections at all. Twenty-four dermatologists did not use the drug for various reasons, mostly because they were afraid of the toxic effects. Only two dermatologists were enthusiastic about the systemic use of these compounds; one took them himself and gave them to his 4½-year-old daughter. Eight were vigorous in their condemnation of the use of these drugs, which they regarded as producers of serious reactions. Practically all others commented that their results were so poor as to show that while these psoralens might indicate an advance in the treatment of vitiligo they are certainly far from the answer. The breakdown in results is shown in the table.

Repigmentation After Use of the Psoralens

Method of Treatment	Cases, No.	Number Achieving Repigmentation				
		100%	75%	50%	25%	0%
Local	231	10	4	5	152	60
Systemic	999	31	6	286	338	338
Combined	113	0	0	17	55	41

It is rather interesting that all of the cases of complete or almost complete repigmentation were reported by 8 of 76 dermatologists who used the drug. All the rest reported 50% or less repigmentation in all their cases. In the present survey of the largest series reported to date, a really satisfactory result was obtained in 7.4% of 1,343 patients and in only 3% of 999 who were treated systemically. Admittedly there is a margin of error in a questionnaire type of report, but the large number of cases and the fairly consistent effects obtained by the majority of dermatologists perhaps reduce this error to statistical unimportance. Fitzpatrick, who is one of the leading authorities on pigment metabolism, reported at a recent meeting of the American Dermatologic Society that two to three years ago he had 150 to 200 patients under such treatment but during the past year only 4, a fact which would certainly indicate waning enthusiasm.

Sulzberger[15] stated that treatment response, even in the same individual, is erratic and that one course may give satisfactory results but on repetition may fail to do so. Treatment may have to be extended over a period of years. Many have commented that even during treatment new vitiliginous patches may appear and when therapy is discontinued the patient often relapses to the pretreatment status. When repigmentation occurs it often does so symmetrically.

Reactions

Immediate reactions reported with systemic use of the psoralens consist of nausea, vomiting, headache, gastric burning, excessive sweating, local redness, increased nervous tension, urticaria, oral and rectal bleeding, and albuminuria. Contraindications to systemic treatment are given as nephritis, hepatic insufficiency, diabetes, gastrointestinal abnormalities, hypertension, and cardiac disease.

During the early evaluation of these drugs, the investigators noted abnormalities in the cephalin flocculation and thymol turbidity liver function tests. However, Fitzpatrick,[17] in a later evaluation of these tests, felt that they were inadequate indicators of the potential liver damage caused by these drugs. He stated that the sulfobromophthalein test is the best indicator and, while he would hesitate to conclude that the drugs are safe for general use, he believed that the likelihood of hepatic damage has been overestimated.

Elwi[18] reported that animals who died of an overdose of 8-methoxypsoralen showed at autopsy pronounced changes in the adrenal glands, congestion and rupture of the sinusoids, total lipid exhaustion, degenerative changes of the liver, and some cloudy swelling and glomerular congestion of the kidneys. O'Neill and co-workers[19] noted that mice receiving intraperitoneal injections of 8-methoxypsoralen one hour prior to ultraviolet exposure exhibited severe erythema and an incidence of ear tumors of almost 100% as compared to 68% in a control group. Interestingly, the incidence of tumor development was less in the treated group than in the control group, to whom the drug was administered orally. Griffin and workers[20] have noted that with exposure to long-wave ultraviolet light, which is normally harmless, erythematogenic and carcinogenic effects were obtained with prolonged administration of the psoralens to white mice. Also, there was a high incidence (20%) of cataracts in the treated group but none in controls. They postulated that the slight long-wave ultraviolet emission from ordinary fluorescent lamps may possibly be sufficient to activate such changes if the animals are sensitized by the psoralens.

Rothman, in discussion, stated that if the long ultraviolet wave lengths (>3,650 A) which are emitted by sun and also by artificial fluorescent lights in offices acquire biological effectiveness through increased photosensitization and the potency of producing cancer and cataracts, dermatologists should take a strong stand against their use. Fitzpatrick stated that the production of cancer under the experimental conditions used by Griffin has little application to the problem in man. He felt that conditions are not comparable, in that the dose given was far in excess of that used in man and the intensity and duration of long-wave ultraviolet light was of a degree quite impossible to obtain in sunlight. He further stated that he was unable to produce eye damage in albino guinea pigs by giving large doses of psoralens orally in conjunction with daily exposure to long-wave ultraviolet light over a period of nine months. Knox, however, pointed out that a man taking psoralens can be burned by the normally harmless Wood's light, as demonstrated by photographs of Stegmaier, and, consequently, that some of the findings in experimental animals are transferable to man. It would thus appear that final evaluation of the toxicity of this drug (which has to be taken over long periods of time and in repeated courses) is far from complete.

In the questionnaire two dermatologists reported jaundice within several weeks after oral administration of 8-methoxypsoralen had been started, and five reported abnormal liver function tests. Other unusual reactions noted were vertigo, pruritus vulvae, toughening of the nails, and appearance of eczematoid psoriasiform plaques only in areas of vitiligo. One dermatologist used 8-methoxypsoralen, with no undesirable effect, in two patients who had had hepatitis previously.

The mechanism of the action of the drug is unknown. Lerner states that there is no effect on the tyrosine pigment system unless possibly as sulfhydryl inhibition. Becker,[21] who studied histological changes in normal subjects who ingested 20 mg. of the drug daily followed by ultraviolet exposure, found that the most prominent change in the skin was a thickened, horny layer, resulting in an extremely compact layer and the formation of a stratum lucidum which is usually found only on the palms and soles. Becker feels that the natural exfoliation is thereby cut down and the pigment granules which normally are cast off are retained. The skin is thereby darkened and more responsive to ultraviolet stimulation. This type of change has been noted in the skin in general as a protective mechanism against solar dermatitis. Jarrett[22] noted that the melanocytes are present in the achromic patches of vitiligo but fail to be stimulated to produce melanin by ultraviolet light. Many other theories have been advanced concerning pathogenesis, but none has been experimentally proved.

Tanning Effects

During the course of the evaluation of the psoralens in vitiligo, another possible effect was reported—the ability to increase the tanning capacity of the skin. Lerner[23] noted that three of nine patients reported an increased tolerance to sunlight after oral administration of the drug. He then gave the drug to three albinos, who also believed that it conferred protection against the sun. Fitzpatrick[24] noted augmented tanning effect in patients taking up to 30 mg. per day two hours before sun exposure; but with doses over 30 mg. all the responses, that is, not only tanning but also erythema and blistering, tended to be augmented. Arnold[8a] believed that the chief value of the psoralens may well be their ability to facilitate suntanning and thereby to protect against sun-induced disabilities.

Daniel, Hopkins, and Fitzpatrick,[25] in an attempt to evaluate this possible tanning action, conducted a double-blind controlled study of burning and tanning effects in the summer. By random sampling one-quarter of their patients were given placebo, one-quarter active drugs, one-quarter placebo followed by active drugs, and one-quarter active drugs followed by placebo. A high percentage of patients were blue-eyed blondes. The 106 patients studied were unable to discriminate significantly between lactose placebo and 8-methoxypsoralen, as to both their sunburning and their tanning effects. Oddly, some examining physicians who did not know they had been giving placebo were enthusiastic about response. Here are a few comments from these physicians: "Tanner than ever," "Stayed out whole days without burning," "Increasing exposure and increasing drug dose without effect except more tan and no burn," and "wonderful." With masterful understatement, the authors conclude that perhaps the "testimonial" type of reporting has a high inherent error. Tanning effects apparently need to be studied by more objective criteria.

Since the toxic and photodynamic effects are as yet incompletely evaluated, it seems premature to use these drugs purely for cosmetic tanning. Certainly the statement of a pharmaceutical company that "thousands of physicians have employed these products for this purpose . . . without undesirable effects" is misleading.

Because of the reputed tanning effect, others have attempted to use the psoralens for conditions in which protection against the sun's rays is desirable—for example, in light-sensitive eruptions. No consistent results have been noted. In the questionnaire, good results were reported by one dermatologist in 3 of 5 cases of polymorphic light sensitivity and by three dermatologists in a total of 19 cases of various types of photosensitivity. It was used by 14 other dermatologists for a wide range of eruptions known to be aggravated by sun, with indifferent results. One noted a flare-up in a patient with polymorphic light sensitivity, and Elliott[11] reported two cases of this type of eruption in patients under treatment. Nine dermatologists reported on their use for the promotion of cosmetic tanning on an indefinite number of persons. Five stated that they felt there was a definite tanning effect; four felt that the patients were more impressed than they were. Many commented that they felt this drug should not be given for the tanning effect only since its safety is not completely evaluated.

Savitt[26] reported on its local use in alopecia areata and felt that the patch treated with the drug responded faster than comparable patches treated with phenol alcohol. Sidi[27] felt that favorable response was obtained by oral administration. Sulzberger wondered if a combination of the steroids and psoralens systemically might enhance the regrowth of hair in alopecia areata.

Conclusions

The toxic reactions in animals and the incomplete evaluation of toxic effects in humans certainly should strike a note of caution. Widespread and indiscriminate administration should be deplored and regarded as premature, since there are so many unanswered questions.

What will be the effect of increased sunlight exposure itself on increasing the incidence of carcinoma? Will the drug itself decrease or increase the development of skin cancers since both effects can be obtained by varied administration in animals? Will the "aging process of the skin" be accelerated or delayed? Will the increased melanogenesis activate junctional nevi or enhance the growth of melanomas? What are the harmful effects of long-term administration of these drugs on the gastrointestinal tract, liver, and kidneys and in humans with chronic disease or disability? How close to the 3% "cure" rate in vitiligo is the spontaneous cure rate? Do these drugs really increase tanning, and, if so, will those people who thereby expose themselves to sunlight be more subject to those afflictions to which excessive sun exposure makes them prone? Until these and undoubtedly other questions are answered, extreme caution should be exerted and the use of these drugs should be limited to experimental study.

ALTERED PROGNOSIS WITH CARDIAC MASSAGE

CARDIAC RESUSCITATION IN ACUTE MYOCARDIAL INFARCTION—REPORT OF TWO SUCCESSFULLY TREATED CASES

Stewart N. Nickel, M.D.
and
Henry H. Gale, M.D., Detroit

In two instances patients with previous symptoms of myocardial infarction collapsed suddenly and became pulseless. Artificial respiration was given by insufflation, and immediate thoracotomy was performed to permit rhythmical manual compression of the heart, which was in a state of asystole. Intracardiac injection of 0.5 cc. of 1:1,000 aqueous solution of epinephrine was followed by ventricular fibrillation. Normal cardiac rhythm was restored by use of an electrical defibrillator in each case, and both patients survived without signs of injury to the brain. This is in accord with other published data indicating that these methods of resuscitation, if applied without delay, greatly improve the prognosis of patients with acute myocardial infarction.

The unusual occurrence of two successful cases of cardiac resuscitation outside the operating room in acute myocardial infarction within a three-week period at this hospital gave impetus to the present study of cardiac massage. The results of this investigation indicate that cardiac massage can alter the dire prognosis of patients with ventricular fibrillation or cardiac arrest complicating acute myocardial infarction.

With the number of recently reported cases of successful myocardial resuscitation in the last several years, cardiac massage has been thought of as a modern innovation. However, a review of the available literature indicates that the earliest attempt at cardiac massage occurred in 1874[1] and the first successful resuscitation in 1902.[2] After this, there were other sporadic case reports of successful cardiac massage and defibrillation carried out in the operating room where surgeon, anesthetist, and equipment were immediately available. It was not

---

From the Division of Adult Cardiology, Department of Medicine, Henry Ford Hospital.

until 1953 [9] that successful cardiac massage outside the operating suite was reported in the available literature. The present paper adds two more successful cases of cardiac resuscitation in acute myocardial infarction performed outside the operating room.

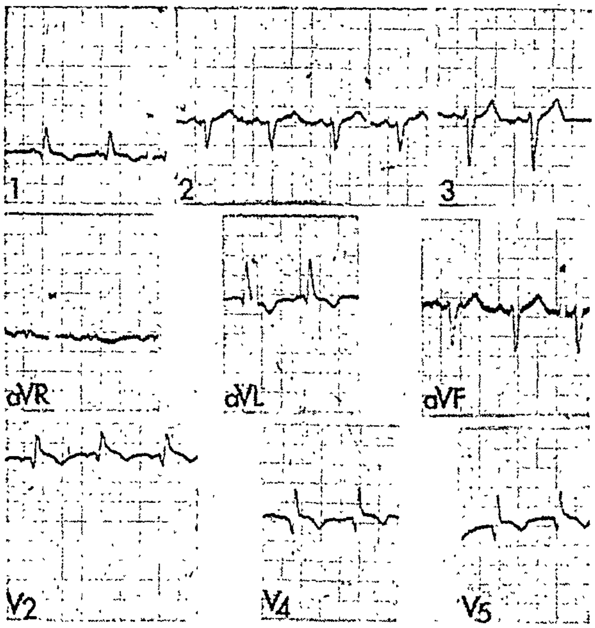

Fig. 1 (case 1).—Electrocardiogram taken two hours after cardiac massage, showing findings consistent with acute anterior myocardial infarction.

Report of Cases

Case 1.—A 53-year-old man was initially seen on Aug. 24, 1958, at the Henry Ford Hospital in the emergency room, where he registered with the chief complaint of left arm pain of several hours' duration. While removing his clothing in one of the examining booths, he collapsed to the floor. Both a surgical and a medical doctor in adjoining booths were able to reach him immediately. He lay on the floor in a tonic convulsion with contraction of masseter and extensor body muscles and with progressively increasing facial cyanosis. Rapid evaluation revealed the patient to be essentially dead without heartbeat, respiration, or reflexes. An airway was inserted, and intermittent positive-pressure breathing was initiated approximately one to two minutes after collapse. After the precordial area was pounded several times without results, an incision was made in the left fifth interspace. There was no bleeding from the skin and subcutaneous tissues, and the incision was extended into the thoracic cage. As rib retractors were applied, the lungs were seen to be expanding well. Cardiac massage, with use of the posterior approach and upward-palm-pressure technique, was begun by Dr. Emir A. Zikria and continued in teamwise fashion two to three minutes after collapse of the patient.

Initially no cardiac contraction was felt or seen through the pericardium, but after intracardiac injection of 0.5 cc. of a 1:1,000 aqueous solution of epinephrine, ventricular fibrillation occurred. The defibrillator was prepared, and 0.8 mg. of lanatoside C (Cedilanid) was injected into the heart for the purpose of strengthening the heart once fibrillation was stopped. Thirty minutes after initiation of cardiac massage, an alternating current was passed across the heart and apparent normal cardiac rhythm established. Bleeding became more active from the operative site, and the patient became very restless. He was taken to the operating room and his thoracotomy wound repaired. At this time, a small area of myocardial discoloration was noted on the anterior surface of the heart.

An electrocardiogram (fig. 1) taken in the recovery room immediately after surgical repair showed a normal sinus rhythm and changes compatible with an anterior myocardial infarction. A subsequent electrocardiogram (fig. 2) confirmed these findings. The patient was awake and alert eight hours after cardiac massage, with no evidence of brain damage. He told of having exertional left arm pain for four years; however, events of the day prior to his collapse were not recalled. Methoxamine (Vasoxyl) hydrochloride and levarterenol (Levophed) were needed for 48 hours to maintain the patient's blood pressure. There was no sign of oliguria, and his urinary output was excellent.

Laboratory studies the day of admission revealed a normal hemoglobin level. The white blood cell count was 19,000 per cubic millimeter. Urinalysis showed a specific gravity of

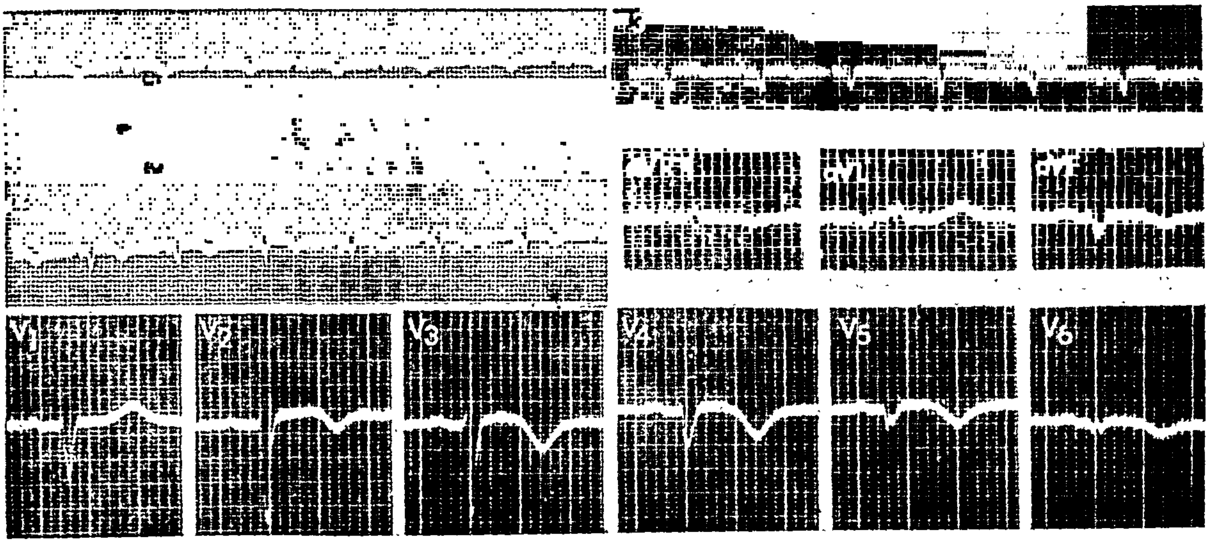

Fig. 2 (case 1).—Electrocardiogram taken four days after cardiac massage, confirming diagnosis of acute anterior myocardial infarction.

1.020, acid, albumin 4+, Benedict's test result negative, granular casts, many red blood cells, and 6 to 8 white blood cells. The urine cleared in seven days. The serum transaminase level was 150 units two days after admission; it decreased to 31 in 5 days and to 16 in 10 days. Initially chest x-rays were clear, but within four to five days a small collection of fluid was noted at the left base. The patient recovered uneventfully and is, at the time of writing (six months after admission), asymptomatic.

Case 2.—A 40-year-old man was first seen in the outpatient clinic on Sept. 19, 1958, with the chief complaint of transient, burning retrosternal pain of four days' duration. The pain was present only with activity and radiated to the left shoulder and down the inner aspect of the left arm. A physical examination gave normal findings. The blood pressure was 140/90 mm. Hg and the pulse rate 72 per minute and regular. The initial impression was coronary artery insufficiency with impending myocardial infarction, and the patient was admitted to the inpatient service. The transaminase level determined at this time was 12 units, and an electrocardiogram showed, as the only abnormality, a slight ST-segment depression in leads V_2 through V_4. While the medical floor resident was making rounds the next morning, the patient's respirations suddenly ceased. He appeared cyanotic and lifeless, and no heartbeat was audible. Approximately three minutes after his collapse, a thoracotomy was performed by Dr. M. A. Block. Cardiac massage and mouth-to-mouth breathing was started, and an intravenous cut-down was placed in the patient's right leg. After about 0.5 cc. of a 1:1,000 aqueous solution of epinephrine was injected into the heart, weak ventricular fibrillation started. The patient was taken to the operating suite for defibrillation with the defibrillator and surgical repair 45 minutes after arrest. Levarterenol was used for 72 hours to maintain the patient's blood pressure. Urinary output was good. There was no suggestion of cerebral damage, and the patient talked rationally about eight hours later.

Laboratory studies obtained just after the cardiac arrest revealed a white blood cell count of 14,000 per cubic millimeter, hemoglobin level 12.6 Gm.%, and nonprotein nitrogen level 30 mg.%. Urinalysis revealed a specific gravity of 1.014, neutral, albumin 1+, Benedict's test result negative, few hyaline casts, 25 red blood cells, and 50 white blood cells. The transaminase level remained at 100 units for three days and then decreased to 60 units on the fourth day. Chest x-rays revealed a minimal amount of fluid in the left lung base. The patient was asymptomatic five months after his cardiac standstill. Electrocardiographic findings (figs. 3 and 4) had been consistent with an acute anteroseptal myocardial infarction.

The medical records of five cases of cardiac arrest in acute myocardial infarction with cardiac massage at this hospital were reviewed (see table).

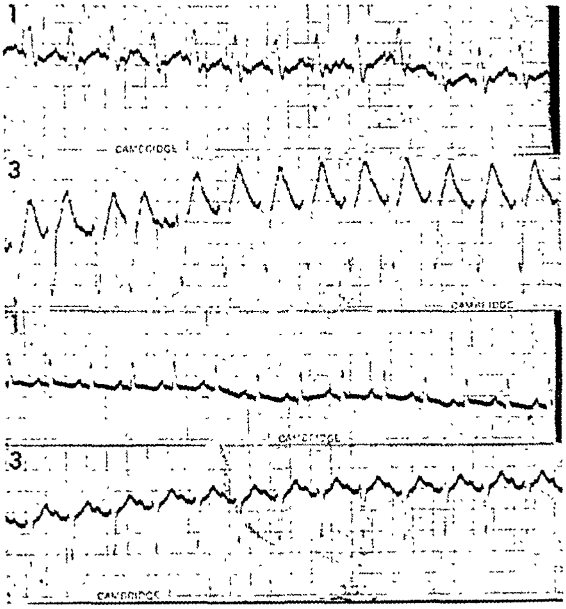

Fig. 3 (case 2).—Electrocardiogram taken *(top)* two and *(bottom)* five hours after cardiac massage.

In all of these cases, massage of the heart was performed either in the emergency room or in the patient's hospital room. Of these five patients, three presented the clinical picture of an impending myocardial infarction. Laboratory studies prior to cardiac arrest were available in two. Electrocardiograms showed ischemic changes, while the white blood cell count, sedimentation rate, and trans-

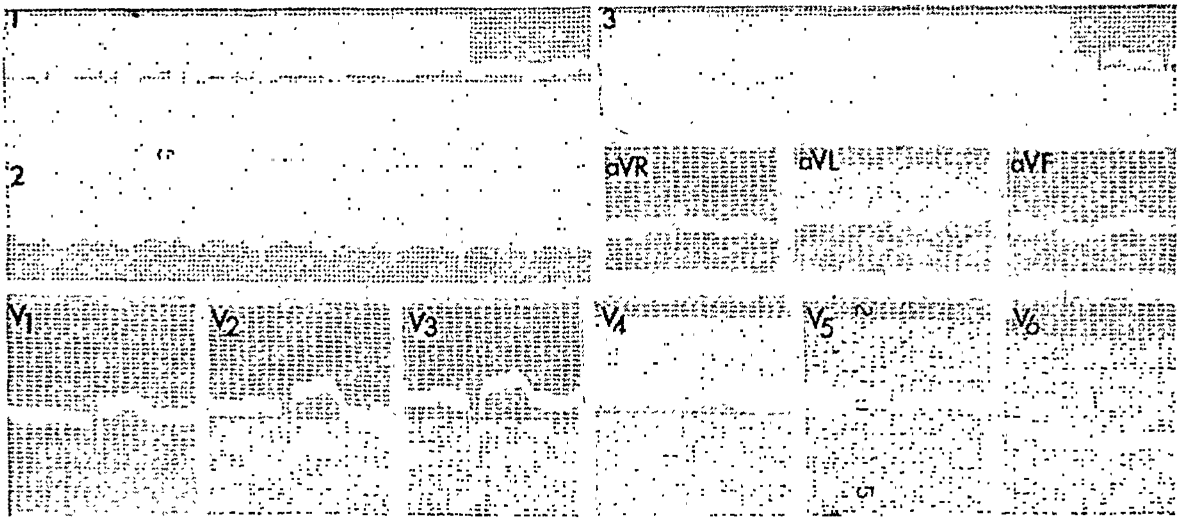

Fig. 4 (case 2).—Electrocardiogram taken three days after cardiac massage, showing findings consistent with acute anteroseptal myocardial infarction.

aminase level were normal. The fourth patient was treated for a pulmonary infarction and initially thought to have a normal cardiac status. The fifth patient was an elderly diabetic with severe chronic congestive heart failure, shown to have an old myocardial infarction at autopsy. At the time of cardiac arrest, a rapid examination was carried out on each patient. The examining physician noted a cadaveric appearance to the body in each case and was not able to detect any respirations, heartbeat, or reflex response. Cardiac resuscitation was carried out successfully in four of the five patients. However, two died shortly after massage. The cause of death in one of these patients was probably brain damage secondary to poor initial pulmonary ventilation. The other patient died from widespread embolic occlusion 10 minutes after massage. The unsuccessful case of cardiac resuscitation was in an elderly man with diabetes mellitus and severe congestive heart failure. Two patients, whose cases are reported above in detail, are alive and well at the time of writing and show no evidence of brain damage.

Results of Cardiac Massage in Five Men with Acute Myocardial Infarction

	Case No.				
	1	2	3	4	5
Age, Yr.	53	40	38	50	60
History					
Previous myocardial infarction	None	None	None	None	Anteroseptal myocardial infarction
Previous heart disease	Slight transient angina, 4 yr.	None	None	None	"Arteriosclerotic heart disease," heart failure
Chief complaint	Episodic pain in left arm, 12 hr.	Impending infarction, 4 days	None	Impending infarction, 12 hr.	None
Location at arrest	Emergency room	Inpatient	Inpatient	Emergency room	Inpatient
Treatment after arrest					
Pulmonary ventilation	IPPB*	Mouth-to-mouth	Nasally given oxygen, artificial respiration	Nasally given oxygen, artificial respiration, IPPB* 20 min.	Mouth-to-mouth artificial respiration, not continuous
Duration of massage, min.	30	45	5 to start, 45 2nd time	20	20
Intracardiac drug therapy	0.5 cc. of 1:1,000 epinephrine, lanatoside C	0.5 cc. of 1:1,000 epinephrine	None	Epinephrine, nikethamine	Calcium chloride, isoproterenol
Defibrillator	Converted	Converted	Not used	Converted	Not used
Levarterenol	48 hr.	72 hr.	Not used	9 hr.	Not used
Chest pounding	No help	No help	No help	No help	No help
Results	Alive and well	Alive and well	Lived 10 min.	Lived 9 hr.	Died immediately
Electrocardiograms					
Before massage	None ↓	S-T segment depression V_2-V_4 "ischemia" 12 hr. ↓	Normal 1 wk. ↓	S-T segment depression V_2-V_6 normal transient "ischemia" 3 hr. ↓	Old anteroseptal infarction 2 days ↓
After massage	Acute anterior myocardial infarction	Acute anteroseptal myocardial infarction	...	Acute myocardial infarction	...
Consciousness regained and lucid, time	8 hr.	8 hr.	Never	Never	Never
Factor in failure	...	...	Overwhelming emboli	Poor pulmonary aid	Poor health of patient
Autopsy results	...	...	Multiple emboli to brain, lung, and *right coronary* artery	Fresh thrombosis in left circumflex coronary artery	Old anteroseptal infarction, fresh thrombus with posterolateral infarction

* IPPB = Intermittent positive-pressure breathing.

Adequate pulmonary ventilation was as important in the success of resuscitation as the actual cardiac massage and defibrillation. Intermittent positive-pressure breathing and the mouth-to-mouth method were both satisfactory to keep the patient breathing and his blood oxygenated. In contrast, artificial respiration and nasally given oxygen did not provide enough air pressure to fill the lungs completely. Intracardiac administration of epinephrine was used in three cases, and ventricular fibrillation resulted. One patient also received intracardiac treatment with lanatoside C. Whether these drugs were beneficial or not is difficult to say. Levarterenol appeared necessary to maintain blood pressure in the patients who were rescued.

Autopsy material confirmed the clinical evidence of acute myocardial infarction in the three patients who died. A fresh thrombus was found in the left circumflex coronary artery of one, while thrombophlebitis with multiple fresh emboli to brain, lung, and right coronary artery was noted in another. The patient who died almost immediately after cardiac massage had, at autopsy, a fresh thrombus in the anterior descending branch of the left coronary artery and an old anteroseptal myocardial infarction.

Comment

Several theories have been advanced to explain the cause of sudden death in apparently normal persons and those with coronary artery disease. Many depend almost entirely on some type of neurogenic mechanism. White[4] suggested that excess reflex stimulation of the vagus nerve, with paralysis of the pacemakers or ventricular fibrillation, could cause sudden death. Beck and coworkers[5] postulated that death from coronary artery disease occurred in either one of two ways: The majority (90%) were due to electrical instability; the remainder (10%) were due to actual cardiac muscle failure. Oxygen differentials in contiguous areas of heart muscle, such as is produced by coronary artery insufficiency or myocardial infarction, produces electrical currents which are responsible for the arrhythmias that kill. It has been estimated that electrical instability without initial muscle damage kills one-third of all victims with acute myocardial infarction. In the other two-thirds, myocardial damage is present but not significant enough to prevent the heart from responding to cardiac massage. Since it has been estimated that sudden death due to cardiac disease occurs 10,000 times each year in the United States alone, the potential of cardiac resuscitation in patients with coronary artery disease who die because of arrhythmia is great. Four patients presented in the present series (see table) responded to cardiac massage with a normal cardiac rhythm. This would support Beck's theory that most cases of cardiac arrest are due to electrical instability and not secondary to irreparable myocardial damage. The one patient whose heart did not respond in any way to cardiac massage was in extremely poor physical condition.

Bloomfield and Mannick[6] feel that it is necessary to document the myocardial infarction prior to arrest to discern the necessity of thoracotomy. They also suggest that the electrocardiographic changes of myocardial infarction noted only after the cardiac massage in most cases reflect manipulative trauma rather than true myocardial infarction associated with coronary artery disease. In this study, all patients presented without evidence of acute myocardial infarction until cardiac arrest occurred. The acute myocardial infarction itself appeared to be the immediate, initiating event for cardiac arrest. To investigate the possibility that the electrocardiographic changes were on the basis of cardiac massage, the medical records of six living patients who developed cardiac arrest in the operating room, as a complication of operations, were reviewed. No heart disease was evident in any of these patients, and preoperative electrocardiograms were normal. After cardiac massage, no change or abnormality could be detected in repeated electrocardiograms. Cardiac manipulation or massage per se, therefore, would appear not to produce electrocardiographic changes of acute myocardial infarction. The acute myocardial infarction pattern that occurred in the two patients in whom cardiac resuscitation was successful was on the basis of true coronary artery disease. In fact, a damaged area was seen in the first patient during massage.

In the heart with ventricular fibrillation, cardiac massage is necessary as a preliminary measure to improve myocardial oxygenation and tone prior to attempts at electrical defibrillation, and also to prevent a recurrence of the fibrillation. Wiggers[7] demonstrated in dogs that ventricular fibrillation regularly occurred after ligation of a coronary artery. Defibrillation with electric shock was always possible, but fibrillation recurred unless the tie occluding the coronary vessel was removed and myocardial oxygenation improved. Four minutes has been set as the time limit within which adequate circulation must be artificially established.[8] In dogs, complete arrest of cerebral circulation for greater than three minutes and 25 seconds produces irreversible neurological changes.[9] In a review of cases collected from the entire United States, there was a much higher survival rate when the massage was started within four minutes, as contrasted to when it was started after this.

From observation of the two recent cases of successful cardiac resuscitation in acute myocardial infarction and from the analysis of three other cases with massage, an altered prognosis is at hand for many patients who would otherwise die from acute myocardial infarction. If a patient with good myocardial reserve develops myocardial infarction with arrest or ventricular fibrillation, cardiac massage may be a life-saving measure. Immediate restoration of effective circulation, as well as adequate ventilation, is vital.

Summary

In two patients with cardiac arrest in acute myocardial infarction, successful cardiac resuscitation occurred outside the operating room. There is, with cardiac massage, a favorable prognosis in cases of cardiac arrest or ventricular fibrillation in acute myocardial infarction.

SOME NONTECHNICAL ASPECTS OF OPEN-HEART SURGERY IN THE COMMUNITY HOSPITAL

Alfred R. Henderson, M.D., Robert R. Meijer, Ph.D., Harvey Black
and
Georges Oteifa, M.D., Asbury Park, N. J.

Considering present world-wide birth rates and figures relative to the incidence of congenital heart disease, fewer children are given the opportunity for corrective surgery within a year with present facilities than are born eligible within a given day. This fact does not take into consideration surgical candidates with acquired heart disease. Open heart operations are feasible within hospitals at the community level. The equipment needed is not as complicated as so often anticipated, and the chances for success are good if the proper personnel equip themselves with certain unpurchasable principles and if confusing, complicating, and obstructing attitudes and gadgets are kept out of the operating room. Particular emphasis is placed on thorough indoctrination of the entire team in the laboratory. The necessary personnel can usually be found, and the equipment acquired, by smaller communities as well as by larger ones, leaving only certain intangible personal traits to decide success or failure.

Four years of endeavor in the experimental laboratory and operating rooms in community hospitals has afforded ample opportunity to face challenging issues which should be of interest to others embarking on a similar course. Eliminating the purely scientific and technical problems encountered in undertaking open-heart surgery with use of a pump oxygenator, the thesis can be broadened to encompass almost any major, unique, and "drastically new" scientific project at the same civic level of medical and surgical practice. These problems should be of special interest to all young men who wish to go beyond the fringe of established and readily acceptable medical practice.

The subject may be divided into the following headings: (1) the practicability of open-heart surgery in the community hospital; (2) the availability of case material; (3) assembling a team; (4) preliminary experimental experience; (5) preoperative evaluation and selection of patients; and (6) some perplexities encountered at the beginning.

Practicability of Open-Heart Surgery in the Community Hospital

Cardiac surgery with a bypass pump oxygenator has become an established procedure in an ever-increasing number of institutions. To be sure, numerous problems pertaining to details, especially regarding oxygenating mechanisms, remain, but these are rapidly diminishing. Ambition for use of the new operation has become almost irrepressibly contagious among thoracic surgeons throughout the United States, and the problems involved are diminishing through its constant success.

In some institutions, the mechanical heart is in daily use and hundreds of patients owe their survival to it. A survey of the waiting lists of patients referred to some of the more well-known centers indicates increasing acceptance by medical men throughout the world. An impressive listing of cardiovascular anomalies considered applicable to bypass extracorporeal techniques is as follows: Congenital anomalies include ventricular septal defects, single ventricle, atrial septal defects, atrioventricular canal, tricuspid atresia, downward displacement of the tricuspid valve (Ebstein's disease), anomalous pulmonary venous drainage, pulmonic valvular and infundibular stenosis, tetralogy of Fallot, transposition of the great vessels, aortic sinus aneurysm, anomalous coronary arteries, aorticopulmonary window (aortic septal defect), subaortic stenosis, aortic regurgitation, and endocardial fibroelastosis. Acquired anomalies include aortic stenosis, aortic regurgitation, mitral stenosis and regurgitation, rupture of the sinus of Valsalva, intracardiac tumors, thoracic aortic aneurysms, and rupture of the ventricular septum.

Those with the greatest experience have shown that the mortality resulting from the operative intervention in certain congenital anomalies of the heart (e. g., interventricular septal defect), uncomplicated by some additional defects, such as severe pulmonary hypertension, and the effects of time-consuming indecision and unwarranted procrastination, can fall well within the justifiable limits of 2 to 3%. Other lesions of a more complicated and hazardous nature have mortalities well below those for the medical treatments assigned them. A continued downward trend attends operative experience. Indeed, the big "if" has been replaced by the big "when" in the protocols of numerous medical centers in the United States.

From the surgical services of the Fitkin Memorial Hospital, Monmouth Medical Center, Riverview Hospital, and St. Barnabas Hospital.

Still, as could easily have been predicted, far too many physicians have been little impressed or influenced by this giant step of surgical advancement. One of the important purposes of this paper is to reduce some of the unnecessary fears associated with the undertaking of this work, while arguing that open-heart surgery is entirely within the realm of a great many small city and community hospitals. It will be repeatedly pointed out that the possession of certain unpurchasable and intangible qualities will better determine its achievement than the physical plant and imposing props so often used as excuses for performance in some communities.

Availability of Case Material

The availability of patients will be determined by two factors: (1) the local incidence of recognized operable heart disease and (2) the cooperative efforts of regional colleagues in referring cases.

Incidence of Operable Heart Disease.—A completely acceptable estimate of the incidence of congenital heart disease in the general population is not yet available.[1] Most reports seem to be much too low. In view of the uncertainty of diagnosis and the widespread unfamiliarity with anomalous heart conditions, this is not surprising. Incidence reports from large series of births, postmortem examinations, and routine hospital admissions vary greatly (from 0.5 per 1,000 to 1.25 per 100). Figures based on routine examination of school children are also fallacious, since the highest incidence of death from congenital heart disease in any given year occurs during the first year of life.

Congenital and acquired heart disease occur with about equal frequency in the pediatric age group.[2] British authors report an over-all incidence of congenital defects of the heart of about 3 per 1,000 births and 1 per 1,000 at 10 years of age. Richards and associates,[3] reporting on 60,000 babies in New York City, place the figure at about 0.83%, including stillbirths. Lillehei and co-workers [4] state that about 50,000 infants born in the United States each year possess some form of anomalous heart. Considering present world-wide birth rates, this means that 2,000 infants with congenital heart disease are born every 24 hours.

Even more significant than mere figures is the fact that most of these infants possess correctable defects when techniques of open-heart surgery can be applied. Lillehei and co-workers [4] emphasize the all-important fact that, actually, less children are being given correction in a year, with present facilities, than are born eligible for operation within a given day. Though the figures are much less accurate than those for congenital lesions, a conservative estimate places at least 25,000 persons eligible annually in the United States for operation for acquired cardiac diseases.[4] This is all the more reason to reemphasize the need, the country over, for less complacency and apathy and more purposeful activity.

Keith and associates [5] report that congenital heart disease is the most common form of heart disease in infancy and childhood, rheumatic heart disease running second. Even a most superficial glance at any group of figures indicates the potential in terms of availability of clinical material. Indeed, the majority of patients arriving at the large medical centers have been sent from communities with inadequate facilities, some of them great distances away.

No colossal amount of graduate training will be required of the man in practice to recognize and properly channel patients suitable for more refined examination and possible operation. In the words of Osler: "The environment of a large city is not essential to the growth of a good clinical physician. Even in small towns a man can, if he has it in him, become well versed in methods of work, and with the assistance of an occasional visit to some medical centre he can become an expert diagnostician and reach a position of dignity and worth in the community in which he lives."[6] To know just what should be done is the first step; then to do it or get it done comprises the total philosophy of practical life. Convincing the practitioner, internist, and pediatrician in the community that local diagnostic and surgical facilities might be as good as those of the large city medical center is no painless and artless feat. We often speak of the need for laboratory space and materials, of aid and grants from this and that agency, but we so seldom openly speak of our most urgent needs: a genuine interest on the part of others within the medical precinct, unsolicited encouragement and reencouragement in the face of success and failure, purposeful and constructive discussion, and the offer of assistance and patient, understanding silence. The routine referral of available clinical material is a measure of final success; referrals during the trying days, when everything seems more potential than actual, are a measure of the faith and good will that make success inevitable. A man, or a team, in an unsettled environment cannot compose a peak performance.

Assembling a Team

One of the obstacles to be hurdled early in the course is the misguided notion that only by the assemblage of a vast throng of superscientists can this project be accomplished. Those who have not passed beyond proprietary literature and newspaper science are awed by the photographs depicting operating room scenes where, somewhere in the midst of the complex wilderness of gadgets and staff, is a patient undergoing open-heart surgery. The "pinball machine" effect would sometimes make a Rube Goldberg contrivance Arcadian by comparison. Nothing could be further from the truth.

To be sure, in some instances where a great deal of basic physiological data are to be obtained during the course of an operation, many recording and measuring devices will have to be used. This, however, must be differentiated from the mere monitoring of a patient through the procedure when additional or superfluous data are not absolutely necessary. Simplicity should be the governing rule in any area where the prime interest revolves around the performance of an operation per se rather than the gathering of coincidental scientific data. Every individual, each control, every recorder, and all connections and lines are potential sources of hazard to the patient. No effort should be allotted to unnecessary gadgets or experimentation. The prime interest of the team at the community hospital is the operative intervention on an anomalous heart with the swiftest and safest route between the diagnosis and the accomplished operation. Fundamentally, a team need consist of two or three surgeons, one scrub nurse and her personal assistant or circulating nurse, one monitoring cardiologist, one pump "engineer" and his assistant, a laboratory technologist, and the anesthetist and his assistant. Each member of the team must be thoroughly indoctrinated in his role by repeated performance in the experimental laboratory long before the final move into the operating room. Disciplinary repetition in the laboratory has made each individual procedure as perfect and mechanical as that of eating a meal.

No matter how "simple" such devices as mechanical hearts may become, or how readily patients and colleagues accept the new technology, it is a foregoing truth that many hours will have to be spent by the surgical team subjecting themselves to the nurturing experiences gained only through repeated experiments in the laboratory.[7] "There is no more potent antidote to the corroding influence of mammon than the presence in a community of a body of men devoted to science, living for investigation and caring nothing for the lust of the eyes and the pride of life."[8] Of such material must a team ideally be constituted.

As part of the team it may well be necessary to include persons who are otherwise employed as engineers, physicists, steamfitters, and even veterinarians—anyone who can and will contribute a needed talent to the fulfillment of the project. A community is composed of a heterogeneous group of people of varying backgrounds and training. Much valuable aid can come from those who are so often willing to contribute to any purposeful effort. Indeed, this is a distinguishing feature of the community hospital setup. Repeated and motivated experiment, attention to minute details, the capacity for work before 9 a. m. and after 4:30 p. m. and Saturdays and Sundays as well, capacity for continued learning, the ability to keep from becoming too easily satisfied, the desire for progressive improvement, and many more intangibles, unpurchasable or obtainable by diplomas and degrees, are the necessary ingredients for a successful team. No amount of building space, grants-in-aid, or fancy and friable glassware will make it work.

Much debate goes on concerning the good and less desirable features of the various mechanisms available—bubblator versus diffusator, finger pump versus roller pump, heating versus cooling, or rubber versus plastic. Amid the confusing clamor there rises one unmistakable fact: some group, or groups, has made every kind of pump and oxygenator work within the justifiable region of safety. You cannot argue with success, and though one way may be somehow better than another there is the undisposable truth that the team is the most important single factor in success. Unsuccessful experiences will least and last of all condemn the human part of the mechanism.

Preliminary Experimental Experience

Mechanical heart-lung machines, though now flagrantly advertised in medical journals as seemingly "ready to use," cannot be bought and assembled like "do-it-yourself kits" and be made to work. Once assembled, the product becomes unlike any other on earth, appearance notwithstanding. No quantity of available funds can buy such a machine ready for use. There is much to be learned concerning its performance under every variable condition of temperature, flow-rate variation, and flow-volume conditions, the amount of oxygen required under any condition of flow, the adaptability to varying patient size, and a multitude of other inconstant details of performance.

The answers to the many basic factors to be learned are not all found in articles or in the results of any other man, machine, or group. There is no effortless or painless way of working out the obstacles and wrinkles; there is no pleasant and palatable way for arriving at even the simplest of principles that need to be understood. Work is the magic word; it is the open sesame to achievement. Without work, without the willingness to repeat experiment after experiment until there remain no unanswered questions regarding safety within reason, a man has no right to transport his equipment from the experimental laboratory to the operating room.

This does not mean that an impressive number of experimental successes need be on hand for reporting, though some seem to relate success to large sums of figures. We know of one group who operated on 140 dogs before a survival was achieved and of another who became repeatedly successful after the fifth animal experiment. There is no doubt in our minds that one group paid more attention to details than the other. No one doing experimental work in the community hospital, where animals, money, time, and effort may exist at a greater premium, can afford unnecessary waste in any direction. The prime motives should be not to design some new freak, basically unlike anything else on earth, but to assemble an apparatus from units known to be useful and practicable and to get it to work so that the community can benefit positively from its presence. Alterations in design and expensive tool and die work should be left principally to the large centers where money, manpower, time, space, and available machine shops are accessories to routine performance.

To visit groups working elsewhere, to spend sufficient time with others who have pioneered and won success, will prove time-saving and effort-saving. It is also an inspiring experience to witness success. It is encouraging to watch another group successfully function together. It is a tonic beyond words to witness an aspiration of your own come true elsewhere—nothing else is more reassuring.

It is important to send all members of the team on such "tonic tours." Scrub nurses, private duty nurses, laboratory technicians—all have much to learn, and there is no learning that equals learning at first hand, which will prove an investment beyond decimal points and dollar signs. The day probably will never come when the perfect, tailor-made machine, devoid of human error in its mechanism and running, will be available. Those who sit idly by, waiting for this era, always find reasons for justifying idleness and poor performance. Progress has been the accomplishment of those who were ever fearful that they could not do enough and not of those who were afraid they were doing too much or more than their share.

Preoperative Evaluation and Selection of Patients

Again, illustrations and reports of monitoring appliances and recording apparatuses serve to confuse uninitiated minds. There is no intention to degrade, decry, or criticize the larger institutions that are doing an important job of gathering physiological data about disease. But a distinction must be made for the man in daily practice between the study of patients for purposes of attaining myriads of different academic data and the study of patients merely for making a working diagnosis. One actually needs to invest in only a few relatively simple pieces of apparatus to carry out the everyday needs for diagnosis and evaluation of patients for cardiac surgery. Aside from the routine studies (electrocardiograms, x-rays, and the usual laboratory tests), cardiac catheterization and, occasionally, angiocardiography are indispensable to the evaluation of the patient with congenital heart disease; such studies give sufficient data for a working diagnosis on which one can determine the need for surgery. Indicator dye dilution curves, phonocardiographic recordings, and electrokymography yield some additional data but may unnecessarily overburden the minds, pocketbooks, and available time of the part-time type of team which can be assembled in the community hospital.

After all, what precisely does the surgeon need to know other than a tenable diagnosis? Intracardiac and pulmonary vascular pressures and sometimes pulmonary arterial wedge pressure curves, pressure gradients across valve orifices, sites of shunts, and position of anomalous vessels are the basic preoperative requisites. With the dissemination of available, trained, thoracic surgeons, the stimulus is present for many small hospitals to incorporate these basic studies in their work-a-day protocol.

The most common error from the surgeon's point of view, associated with impatience to get started, is to select almost any kind of case for his initial efforts. Knowing that much is to be gained by a successful operation on a patient with an advanced cardiac problem, for whom there is no help from any other source, he is often willing to take the long chance—ignoring the fact that surgical failures have a more profound reverberation than medical failures. An early high mortality is much less tolerated at the community level, where criticism of new procedures is readily given. But the surgeon often finds himself in a whirlpool of confusion, being denied relatively "healthy" patients who can better tolerate the operative insult and being given the symptomatic cases which are the most impressive from the unreasonable clinician's viewpoint. A patient without symptoms is much more apt to be kept from the surgeon. In congenital heart disease it is much wiser to operate on existing pathology and not on the patient's symptoms.

Pulmonic stenosis (valvular and infundibular), interatrial septal defects, and pure interventricular septal defects without significant pulmonary hypertension constitute cases ideally suited for a beginning. Gradually, tetrology of Fallot, anomalous pulmonary venous drainage, acquired valvular heart disease, and others can be added as operative experience and acceptance are gained.

Some hospitals set up conferences comprised of members of the general staff to decide on the selection of cases. This is often fallacious from first thought, since such a group consists in the main of "voting members" who are ill-equipped, insufficiently interested, and unlearned in the field and who often gain very little from this real opportunity to learn. It is far better to set up a small group of genuinely interested men, internists, pediatricians, laboratory personnel, and the catheterization and surgical teams, to make these decisions. In this group there should be no room for the man who makes little or no earnest effort to acquaint himself with the fundamentals and who only visits the larger centers, availing himself of the voluminous written material and attending regional and national meetings. It has been stated that the clinical material can be found in the community, that the opportunity is always present, and that only work remains as a personal factor to be contended with.

Perplexities at the Beginning

Some intangible qualities of people have been stressed as the most important components of the various factors comprising the organization and functioning of a team. Lest one would be impressed wrongly that certain physical factors are of little consequence, a few words must be said concerning the importance of such tangibles as money and materials, space and time, and personal and personnel problems.

Most community hospital's and sources of funds for medical research are limited in comparison with the sizable grants and budgets of the larger centers. Being restricted, one cannot buy everything one would like to buy. This may not be such a handicap after all.

Much of our limited time and effort can be wasted on "gadgeteering." More than one great laboratory is arrayed with functionless expenditures, representing previous pursuits long since passed up for seemingly more worthwhile pursuits. The community hospital and the community can ill afford purposeless expense or the space to function as a museum.

One of the first principles, then, is to recognize the limitations of activities. A man who undertakes this project at the community level lives three distinct lives—one for the project, one for his practice, and one for his personal or family life. He becomes a part-time devotee to each. He is constantly faced with decisions as to which to devote himself to, since, when he decides on one, he automatically decides not to do another. His life becomes crowded with little or no time for refreshing unessentials; when lack of money or energy does not limit him lack of time does. He soon finds himself in the same dilemma as the youngster with a penny who wants one of each thing under the counter.

This is no doubt the most momentous task of all—to decide on the goal, strip it of unessentials, and then select the straightest and shortest route to its achievement, appearing unencumbered by a restricted budget, inadequate space, or disinterested and incredulous colleagues. The goal, of course, will be the creation of a relatively simple mechanism capable of maintaining extracorporeal circulation and oxygenation in the safest possible manner. There will be a limit to the sidetracking experiments and other pursuits which may only wind up with a self-satisfying bibliography.

Local and neighboring county and state divisions of the American Heart Association have proved most generous in granting financial aid to community hospitals undertaking such programs. Other organizations and clubs within the community are often likely sources of small annual donations, as well as hospital auxiliaries and interested individuals. The hospital and its administrators should consider the project an investment worthy of space and other resources. Indeed, without this interest there can be no beginning.

The difficulty is that the man or group needing the cash finds it an easy matter to think that others should be ready to part with it. It will take a lot of repeated efforts, speaking engagements, and other methods of public convincing that this, unlike other demands, is more than indiscriminating charity or giving. Every attempt must be made to make such drives for financial aid of an initiating and temporary nature, stressing the eventual creation of a self-sustaining and independent mechanism or one needing a minimal amount of aid for its sustenance. One of the best stimuli for convincing support is activity itself. A group already at work is more apt to receive help than one which spends time sharpening pencils, clearing desks, and waiting for an uninterrupted day, the mood, the money, or other desirables which seldom come without real effort.

Everything comes to him who hustles while he *waits. Hours pass, days go by, and so do the years* and even life itself finding men and institutions nursing intentions. One message, if nothing else, we wish to impart is this:

Given a trained surgeon and an interested and dedicated group of workers in a community hospital, there may be excuses but there are no real reasons why this newest surgical innovation cannot be added to the protocol. Postponement, the putting-off that usually waits for supposedly better times, circumstances, conditions, or machines, may cost the hospital an opportunity to take a giant scientific step forward. Patients, too, will be denied their rightful opportunity for this recent and effective treatment.

321 Sunset Ave. (Dr. Henderson).

This study was supported by grants from the Monmouth County and Morris County (N. J.) heart associations and the New Jersey State Heart Association.

SURGICAL INTERVENTION IN HEMOPHILIA

REVIEW OF THE LITERATURE AND REPORT OF TWO CASES

George R. Pieper, M.D., Seymour Perry, M.D.
and
John Burroughs, M.D., Los Angeles

Two surgical operations on patients with hemophilia are described. One was an appendectomy performed on a 26-year-old man with the laboratory findings and long history of hemorrhages characteristic of hemophilia. The other was a goniotomy in a 7-month-old boy with similar laboratory findings and a history of recent hemorrhages. In both patients the antihemophilic globulin (AHG) concentration was less than 1% on assay. Infusions of fresh plasma were given before operation in both cases, and in the second case assays for AHG showed that adequate levels could be achieved by such infusions provided the apparatus was siliconized, the plasma chilled, and the infusion given rapidly. In the older patient the postoperative course was marked by some bleeding, but both patients recovered.

Hemophilia is a disorder of blood coagulation resulting from deficient plasma levels of specific factors, the most common of which is antihemophilic globulin (AHG), followed in incidence by plasma thromboplastin component (PTC) and plasma thromboplastin antecedent (PTA). Characteristically, the clotting time in hemophiliacs is prolonged, with a normal bleeding time, prothrombin time, and platelet count; thromboplastin generation and prothrombin consumption are abnormal. Brinkhous [1] has classified hemophilia as (1) severe (classic) hemophilia, with essentially no AHG by assay; (2) intermediate hemophilia, about 5% AHG; (3) mild hemophilia, about 15% AHG; and (4) subhemophilia, about 35% AHG. The latter type usually gives a normal coagulation time.[2]

Morbidity and mortality in the hemophiliac undergoing surgery are high; even extraction of a tooth may lead to serious bleeding problems. Craddock and co-workers,[3] for example, reported three deaths in five hemophiliacs after major operations. This report is an analysis of the experiences of various authors relating to the problem of major surgery in the individual with hemophilia. To our knowledge there has been no survey of the literature on this problem since Craddock's in 1948. In addition, we are reporting two patients with severe hemophilia subjected to relatively serious surgical procedures.

Report of Cases

Case 1.—A 26-year-old male student known to have classic hemophilia entered the University of California outpatient department in Los Angeles on July 15, 1958, complaining of recurrent dental abscesses. History included multiple recurrent hemarthroses and epistaxes beginning at age 8 months. Treatment had consisted largely of pressure to affected joints and immobilization. One blood transfusion when he was 2 years of age had caused a severe reaction and none had subsequently been attempted. Family history revealed no "bleeders" in five generations on the maternal side. However, clotting studies had not been performed.

Physical examination revealed an abscess of the lower right first molar tooth, with many other decayed teeth. There was little limitation of motion except in extension of the left knee. Pertinent laboratory findings were as follows: platelet count 117,000 per cubic millimeter (normal 200,000-350,000); coagulation time greater than 36 minutes; prothrombin time [4] was 10.5 seconds (100%); prothrombin consumption (Owren,[5] modified [6]) was zero; and thromboplastin generation (Miale and Wilson [7]) revealed deficiency of a plasma coagulation factor which corrected on substitution of normal BaSO$_4$-treated plasma. AHG concentration was less than 1% on assay.[8] X-rays revealed old arthropathy of both knees consistent with hemophilia.

The patient was scheduled for admission to the University of California Hospital, Los Angeles, for preparation for dental surgery. However, on the evening of Aug. 13, 1958, the patient entered the University of California Hospital emergency room complaining of anorexia, nausea, vomiting, and periumbilical pain of 30 hours' duration. Examination at this time revealed abdominal tenderness which gradually localized in the right lower quadrant, without guarding or rebound. The temperature was 39 C (102.2 F); rectal examination was unrevealing. The physical examination was otherwise as previously described. Urinary sediment contained 8-10 red blood cells per high-power field and 1-4 white blood cells per high-power field. The blood leukocyte count was 14,250 per cubic millimeter. Abdominal x-ray revealed a possible fecolith in the proximal appendix. A diagnosis of acute appendicitis with possible impending perforation was made, and, after considerable deliberation, operative intervention was elected. One unit (250 ml.) of fresh plasma was given intravenously over a period of 30 minutes, followed by a second unit which was allowed to drip during the operation. The clotting time was normal just prior to the operation, but, owing to lack of laboratory facilities at the late hour, AHG levels could not be obtained.

During surgery, which was performed by one of us (J. B.), all unnecessary trauma was avoided. The patient was given a general anesthetic without intubation. A right paramedian incision was made in the lower quadrant and bleeders tied with 0000 silk, with electrocoagulation of

---

From the departments of medicine and surgery, School of Medicine, University of California Medical Center and Wadsworth Veterans Administration Center.

multiple small bleeding points. Serous fluid was encountered on entering the peritoneum. Immediately beneath the incision was a periappendiceal abscess enclosed in omentum, which was entered and suctioned. The omentum was dissected free proximal to the appendix with cautious clamping and ligation of the omental stump with 000 silk. The omentum was thus freed from the appendix and removed. The appendix was then carefully dissected free from surrounding tissues and removed in the usual manner. Three minutes' observation revealed no bleeding. The rectus sheath was closed around a 0.25 in. Penrose drain. Subcutaneous tissue was closed with interrupted 0000 silk around a drain, a light gauze dressing applied, and the patient returned to the ward in good condition. Blood loss was estimated at 50 ml. Pathological examination of the specimen confirmed the diagnosis of acute suppurative appendicitis with focal acute peritonitis.

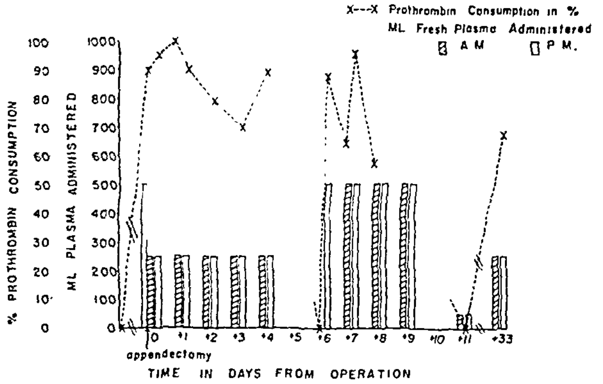

Fig. 1 (case 1).—Prothrombin consumption and plasma therapy in hemophiliac on whom appendectomy was performed.

Infusions of plasma were continued postoperatively. Treatment and results of prothrombin consumption tests are summarized in figure 1. On the ninth postoperative day the patient complained of dyspnea. Venous distention, pulmonary rales, and hepatomegaly were noted. A chest x-ray revealed multiple patches of density in both lung fields. These findings were attributed to hypervolemia secondary to plasma administration. The patient improved rapidly with sodium restriction and interruption in plasma therapy for two days. On the 21st postoperative day slow oozing from the wound site was noted and a subcutaneous hematoma appeared. Several small bleeding points in the drain site were cauterized with silver nitrate and the hematoma was allowed to absorb. Hematocrit levels remained constant throughout. On the 31st postoperative day a draining peridontal abscess in the right mandible appeared and responded promptly to antibiotics. The patient was discharged in good condition on the 39th postoperative day. Dental extractions were postponed at the patient's request.

Case 2.—*A 7-month-old male was admitted to the University of California Medical Center, Los Angeles, pediatrics department, for goniotomy procedure on Sept. 28, 1958.* Previous admissions had revealed multiple anomalies, including congenital adrenal aplasia, glaucoma, and hemophilia. Hydrocephalus was also suspected.

The infant had had a hemorrhage from a femoral venipuncture site previously, and hematochezia had been noted. The family history revealed no other "bleeders." It was not feasible to do clotting studies on other members of the family. Positive findings included a head circumference of 44.5 cm.; ocular tension, with the patient under anesthesia, was 40.6 by Schiøtz's tonometer (normal—less than 25).

Blood studies revealed a plasma factor deficiency in the thromboplastin generation test corrected by $BaSO_4$-treated plasma, and AHG of less than 1% on assay. Serum electrolytes, initially markedly abnormal, were corrected when treatment for the endocrinopathy was instituted. AHG levels are summarized in figure 2.

After preoperative preparation with fresh plasma infusions, the child was intubated and general anesthesia used. Surgery was performed by Dr. Stephen Seiff. Examination showed the corneal diameters to be 13 mm. on each eye, with tension of 5 with a 10 weight bilateral (equal to 40.6 Schiøtz). There were no gross breaks in Descemet's membrane. Bridle sutures were then passed beneath the inferior, superior, and medial rectus with scant bleeding. Goniotomy was attempted in the right eye but the anterior chamber collapsed and the procedure had to be terminated. However, goniotomy was successful in the left eye. Oozing was minimal.

The infant made an uneventful recovery from the goniotomy with relief of increased intraocular pressure. Fresh plasma infusions were continued postoperatively. Management of the hemophilia is summarized in figure 2. Surprisingly low levels of AHG in the infant's blood even after infusions of plasma led to the discovery of unfortunate errors in preparation of the plasma, as will be discussed later. Adequate levels were achieved, however, in both the plasma for infusion and the patient's blood, when siliconized apparatus was used for collection, when the plasma was constantly chilled, and when administration was rapid.

Comment

Surgery in the hemophiliac has always carried with it a prognosis so serious that surgeons have avoided any operative procedures if possible. The table summarizes all case reports in the available literature of major surgery in hemophiliacs. Cases were included when they met the criteria outlined by Craddock,[3] namely, (1) laboratory findings of prolonged clotting time without abnormalities in other tests of the hemostatic mechanism, (2) positive family history, (3) history typical of hemophilia, and (4) occurrence in a male. In addition, most recent reports include assays for specific defects. It should be noted that all of the criteria do not apply to every case. In both of our cases, for example, family history was negative. Absence of a history of bleeding likewise does not preclude the diagnosis of hemophilia. However, previous episodes of hemarthrosis, bruising, hematuria, and

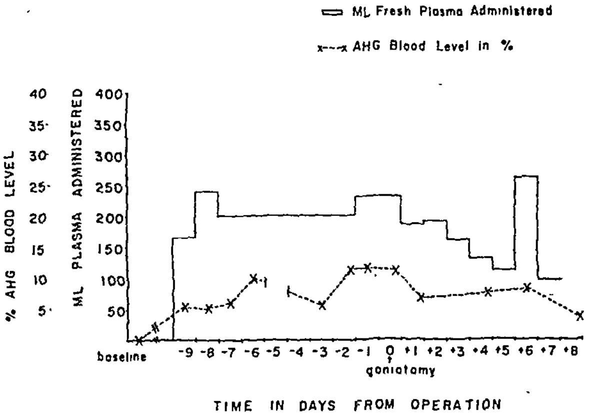

Fig. 2 (case 2).—AHG blood level and plasma therapy in hemophiliac on whom goniotomy was performed.

continued oozing from minor lacerations are found in most severe hemophiliacs and lend support to the diagnosis. Occurrence in the female is extremely rare.[9]

Of the 50 cases listed in the table, mortality from major surgery was 20%; the same mortality applies when only the 24 cases with laboratory-proved coagulation defects are selected. Intra-abdominal operations in 22 proved hemophiliacs of all types resulted in 3 deaths, a mortality of 13.7%. Among 12 hemophiliacs, appendectomy led to three deaths; 2 proved hemophiliacs of 7 undergoing surgery died, a mortality of 28.6%.

† These cases in 1950 and earlier fulfill criteria outlined in text. However, since the thromboplastin generation test and AHG assay were not being done at the time, they can be listed only as "probables."

These mortality figures for hemophiliacs undergoing major surgery are approximately half those reported by Craddock,[3] and are also considerably lower than those of Friedrich in 1935.[10]

For appendectomy, the mortality figures are also approximately one-half of Craddock's figure of 66.6%.[3] The incidence of death in normal persons after appendicitis with rupture and peritonitis, who are treated conservatively and without operation, is 10 to 15%.[11] While hemophiliacs are known to suffer serious complications during conservative management, especially with infections,[12] nevertheless it appears that appendectomy in the hemophiliac is attended by twice the mortality of conservative treatment. Morbidity is also higher in the hemophiliac in whom operation was done. In terms of length of hospitalization, hemophiliacs remain in the hospital an average of 34 days after appendectomy.[13] Normal persons with appendicitis but without rupture have a six-day hospitalization after appendectomy.[11a] Conservatively managed normal persons with appendicitis and abscess formation stay in the hospital only 20.6 days.[11a] Data on the conservative management of appendicitis in hemophiliacs are inadequate. In addition, many of the hemophiliacs studied had life-endangering hemorrhages during the prolonged postoperative course.

Management of hemophiliacs in recent years appears to be improving, an impression substantiated by the report of only 1 death in 17 recent intraabdominal operations. There appears to be an increasing willingness to perform operations on hemophiliacs. Thus, of 45 cases in the literature, half were reported in the last decade.

Major surgical procedures in sites where local hemostatic measures are applicable present much less of a problem than internal operations.[14] For this reason, surgery involving extremities will not be discussed here. The use of local cooling measures to enhance vasoconstriction, and hemostatic substances such as fibrin foam placed into the wound, all help to induce coagulation. However, with bleeding into hollow viscera or into cavities, these measures are not applicable and the possibility of exsanguination is increased.

In case 1 several favorable factors applied: the patient's coagulation defect was known, permitting swift correction; fresh plasma was immediately available; and the appendix was easily mobilized through a bloodless incision. In spite of this good fortune, the patient developed a large hematoma at the operative site.

Both cases 1 and 2, particularly the latter, emphasize the importance of careful collection and rapid administration of blood or plasma. The blood must be collected rapidly in siliconized bottles or plastic bags, without foaming and with constant agitation so as to insure continuous mixing of anticoagulant and blood. Blood or plasma must be administered rapidly. Blood or plasma normally will vary greatly in its AHG content (50-150%), and on exposure at room temperature will lose AHG activity rapidly.[15]

Severe bleeding occurring in a hemophiliac treated carefully to attain a satisfactory laboratory AHG level is unfortunately a common problem. The prothrombin consumption test may also be misleading.[16] No satisfactory explanation can be offered for this lack of correlation until more detailed understanding of the interaction of the various components in forming thromboplastin is achieved. It must be remembered that time alone will determine the prognosis in the hemophiliac undergoing surgery and not necessarily the results of clotting studies. Hypervolemia from plasma administration is a complication occasionally encountered in hemophiliacs. This problem may be managed with exchange transfusions of fresh whole blood or plasma, or concentrates of human or bovine AHG may be used.[17] Unfortunately, bovine AHG preparations are not readily available in the United States, and pooled plasma concentrates carry the risk of infectious hepatitis. Fraction 1 of Cohn, containing a high concentration of AHG, may be of help but varies considerably in potency and may also transmit viral hepatitis. Much work is needed to provide better replacement therapy.

Another complication is the development of a circulating anticoagulant as described by Lawrence and Johnson. This is a grave development and is extremely difficult to handle.

Summary

Two known hemophiliac patients survived operative procedures, one for appendectomy and one for goniotomy. These cases emphasize the importance of careful collection and rapid administration of blood or plasma. Although laboratory methods for the assessment of hemophilia are still inaccurate, management of hemophiliacs in recent years appears to be improving. Of 50 cases in the available literature of persons suspected of having hemophilia and in whom major surgical procedures were performed, mortality was 20%. In 24 such cases with proved hemophilia there was a similar mortality. A mortality of 28.6% was found for appendectomy in proved hemophiliacs. In spite of the better preparation and treatment of the hemophilic surgical patient in recent years, any operative procedure in a hemophiliac remains a grave undertaking.

This study was supported in part by the U. S. Public Health Service, Parke, Davis & Company, Detroit, and the Gladys F. Bowyer Fund.

Technical assistance was supplied by Mary Baker, B.A., and Gloria Paul, B.A.

Dr. Jeanette Schulz granted permission to report case 2.

TREATMENT OF PARALYSIS AGITANS WITH CHLORPHENOXAMINE HYDROCHLORIDE

Lewis J. Doshay, M.D.
and
Kate Constable, M.D., New York

Chlorphenoxamine was administered to 25 patients with paralysis agitans in a preliminary test to determine dosage and observe side-reactions. Thereafter it was administered to 136 patients who had been treated unsuccessfully with other drugs. It allayed tremor only in the occasional patient, and in some the tremor was accentuated. Its most consistent effect was on akinetic, tired, weak patients, who were enabled to move with greater celerity, strength, and endurance. It stimulated without inducing excitement and relaxed without causing flaccidity or enfeeblement. Three case histories illustrate its effects on the disabling symptoms of the patient. The side-effects observed were neither frequent nor serious. Tolerance did not seem to increase with lapse of time, and the favorable effects continued only as long as the drug was administered.

Argument is often heard that we have more than enough compounds for the treatment of paralysis agitans (Parkinson's disease), and some even claim that hyoscine hydrobromide alone can suffice for the care of all the symptoms of this disease. The fact remains that, despite the addition during the past decade of a half dozen new synthetics—trihexyphenidyl (Artane) hydrochloride,[1] cycrimine (Pagitane) hydrochloride,[2] procyclidine hydrochloride (Kemadrin),[3] benztropine (Cogentin) methanesulfonate,[4] ethopropazine (Parsidol) hydrochloride,[5] and orphenadrine (Disipal) hydrochloride[6]—to the older belladonna preparations, those who treat large numbers of patients who suffer from paralysis agitans feel a dire need for more and better compounds, for various reasons: 1. Many patients, especially those suffering from tremor and akinesia, are not helped sufficiently by current drugs. 2. People live longer; hence we see increasing numbers of older patients, many of whom cannot tolerate the available remedies. 3. Drugs tend to lose their beneficial effects with the passing of time, so we must have a large assortment of good compounds for replacement. 4. Some patients tire of any remedy during the long siege of the illness and are forever in search of something new. 5. There are increasing indications that neurosurgery is likely to fail in its anticipated promise of relief, so patients in the foreseeable future will of necessity have to rely on medication for any benefits they are to derive from treatment.

This paper will introduce a new drug, chlorphenoxamine hydrochloride, that has proved beneficial to many of our patients whom standard

---

From the Neurological Institute of the Presbyterian Hospital and the Department of Neurology, College of Physicians and Surgeons, Columbia University.

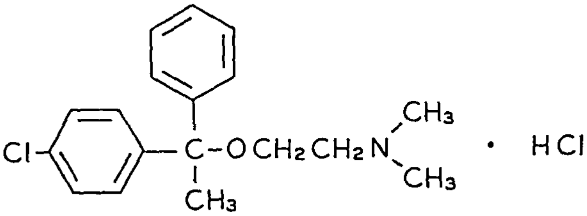
agents for paralysis agitans failed to help. It has been in use in Germany for several years after prior establishment of its therapeutic safety.[7]

Chlorphenoxamine is beta-dimethylaminoethyl (p-chlor-alpha-methyl-benzhydryl) ether hydrochloride. Chemically, it is a derivative of diphenhydramine (Benadryl) hydrochloride, with structure as shown in the figure.

The addition of a p-chlor atom or an alpha-methyl group to the beta-dimethylaminoethyl benzhydryl-ether molecule lessens the antihistaminic action of the compound and increases its anticholinergic action. The addition of both elements serves to accentuate this action. The oral LD_{50} dose in mice is 410 mg. per kilogram, which indicates a high index of safety. Pathological studies of animals that had been fed chlorphenoxamine for long periods failed to reveal any abnormalities in the organs or blood constituents. Hemogram studies in 20% of our patients and cephalin flocculation, thymol turbidity, and urinalysis studies in eight of these patients were all reported normal.

Clinical Material and Procedure

Chlorphenoxamine was supplied to us to determine its possible usefulness in the treatment of this disease. It was provided in the form of 100-mg. capsules and 50-mg. coated tablets. The tablet was found to be more practical and better tolerated and is the form we have continued to use.



Chlorphenoxamine hydrochloride.

The study began with a group of 25 specially selected patients, with the aim of establishing the effects, side-reactions, and range of therapeutic dosage. Some patients, known to possess a high tolerance for drugs, used as much as 600 mg. per day without evidence of side-reactions. Others reported satisfactory results from only 25 mg. of chlorphenoxamine, three times daily, achieved by cutting the tablet in half. However, it became evident early in the study that the optimum dosage for most patients was about 50 mg., three times daily. Some fared better on 100 mg., three times daily, especially the younger postencephalitic patients. It was found better tolerated after meals, with milk, because a few patients complained of indigestion when it was taken with water. There was little occasion for increasing the dosage, as patients tended to remain on therapy with the same amount of drug month after month, indicating that there is little increase in tolerance. In cases where such increase did occur, it was usually after three to six months of use, and the addition of one or two tablets per day served to restore the initial benefits.

The preliminary group of 25 patients was steadily expanded to include 161 patients with paralysis agitans, who were selected only to the extent that they had failed to derive sufficient benefits from other drugs. Among those were 96 males (60%) and 65 females (40%). The youngest was 38 years of age and the oldest 76. In addition to the patients with paralysis agitans, six with senile tremor, three with hereditary chronic progressive chorea with mental deterioration (Huntington's chorea), three with familial hereditary tremor, one with dystonia musculorum deformans, one with hemiballismus, and one with torticollis spasm were likewise studied for the effects of chlorphenoxamine.

The new compound was used alone in 67 patients and was combined with other drugs in 94. Comparisons were made of its action with those of well-known drugs and with placebos. Objective studies were conducted with 12 patients in the laboratory by means of electronic instruments specifically designed for measuring changes in rigidity and tremor.[8]

On the basis of the above studies, clinical observations, and reports from the patient and family, the results of treatment with chlorphenoxamine were classified as failures if no benefits accrued to the patient, if the therapy was discontinued because of side-reactions, or if the patient had not been heard from for more than two months, which meant the allotment of medicament had been exhausted and the patient was dissatisfied. Patients were regarded as "failures" even if they had been on the drug therapy but one day. Since no patient was actually made "worse" by the medicament, no such classification was deemed necessary. The successful results were grouped under the one heading of "improved," because experience has shown that in paralysis agitans it is not desirable to delineate fine shades of change, since the symptoms and behavior of the patient are often influenced by emotional and situational factors and they can vary from day to day.[9] Doubtful and borderline changes were not counted among the successful results. Moreover, no patient was classified as "improved" unless chlorphenoxamine had been used with favorable effects for at least two months.

Results

On the basis of the stated criteria, the results of treatment with chlorphenoxamine are recorded in table 1. It is noted that 53% of the patients were improved. Among those were many who were remarkably benefited by the new compound. The low incidence of disturbing side-reactions made it even more acceptable to the patients. The favorable results were about equally distributed among the older and younger patients (table 2). Thus, 28 (49%) of 58 patients in the 61-70 age range were improved as compared to 15 (55%) of 27 patients in the 41-50 age range. This finding bears special significance, considering that the group of patients with paralysis agitans is becoming increasingly older [10] and that such patients are usually hypersensitive to drugs; hence they respond less favorably than younger patients.

TABLE 1.—*Results of Treatment with Chlorphenoxamine Hydrochloride in 161 Patients with Paralysis Agitans**

Disease Type	Unimproved	Improved	Total
Postencephalitic	14	15	29
Arteriosclerotic	33†	27	60
Idiopathic	29‡	43	72
Total, No.	76	85	161
Total, %	47	53	100

* Fifteen additional patients (6 with senile tremor, 3 with familial hereditary tremor, 3 with hereditary chronic progressive chorea with mental deterioration, 1 with dystonia musculorum deformans, 1 with torticollis spasm, and 1 hemiballismus) were treated with chlorphenoxamine. Only those with hereditary chronic progressive chorea and hemiballismus responded favorably.

† One patient died from a gallbladder operation. Another underwent ultrasonic surgery, so that chlorphenoxamine therapy had to be discontinued.

‡ One patient died from severe burns.

The 47% failures were in large measure accounted for by patients who had tremor as the predominant symptom or those in whom a minimal tremor became accentuated by the drug. Some failures were accounted for by patients who had failed on therapy with all other compounds because of neurotic or unstable components of personality. Still other failures occurred among patients who, through long usage, had become dependent on trihexyphenidyl, cycrimine, or procyclidine hydrochloride and were generally distrustful of a new compound. A few discontinued use of chlorphenoxamine because of genuine concern about side-reactions, such as indigestion, especially where there had been a history of gastric ulcer. Some have not been heard from, and the reason for their dissatisfaction remains unknown.

Aside from numerical findings, the day-to-day experience with the patients served to confirm the outstanding quality of the new product. Not only were the reports highly gratifying but there was a pronounced demand from the patients and family for the drug, to an extent where it was hardly possible to maintain a sufficient supply month after month. This was in sharp contrast to our experience with 10 other new compounds which were being tested at the same time as the chlorphenoxamine. There was no comparable interest in any of the other drugs. Thus, apart from all other considerations, the consistently great demand for chlorphenoxamine was conclusive proof that it was helping the patients more than the other experimental drugs and more than some of the standard agents which they had formerly used.

Chlorphenoxamine exerts a gentle yet potent action, entirely different from that of the parent compound, diphenhydramine. It has a muscle relaxant action far above that of diphenhydramine and also an energizing and stimulating action, without induction of excitement or agitation. Patients are able to move faster and more freely and with greater strength and longer endurance. It helps to loosen rigid muscles, and it successfully counteracts akinesia, tiredness, and weakness. While in an occasional patient it served to allay tremor and excitement, it had the least satisfactory action against tremor, which in fact it tended to accentuate in 16 patients when used alone. However, with addition of ethopropazine or diphenhydramine it was found possible to keep tremor under satisfactory control, sometimes even with the addition of small doses of trihexyphenidyl.

Chlorphenoxamine helped to relax spasm and cramps of somatic origin and was especially beneficial to those who suffered from visceral spasms, or so-called inner tension and tremor. Some patients with frequency and urgency of urination obtained striking relief from its use. The muscle relaxant action is seemingly of a gentle nature, since even in large doses there was no evidence of enfeeblement or flaccidity. The usual duration of action was four to six hours and the onset of action about 30 minutes. However, a few patients were maintained comfortably on one tablet a day.

A number of patients (67) found it possible to discontinue use of all former remedies and to function successfully in their occupations and everyday activities with use of chlorphenoxamine alone. Others found it more advantageous to combine it with trihexyphenidyl (30 patients), benztropine methanesulfonate (25), procyclidine (12), cycrimine (10), ethopropazine (10), and diphenhydramine (5). It combines readily with all agents used for paralysis agitans. Of the 15 patients with extrapyramidal syndromes not associated with paralysis agitans, only the patient with hemiballismus and the two with hereditary chronic progressive chorea with mental deterioration responded favorably.

TABLE 2.—*Age of Patients in Relation to Results of Chlorphenoxamine Treatment*

	Age, Yr.					Total

* One patient died from severe burns.

† One patient underwent ultrasonic surgery and chlorphenoxamine had to be discontinued.

‡ One patient died from a gallbladder operation.

Report of Cases

Chlorphenoxamine was so effective in most patients with paralysis agitans that it is considered desirable to submit several illustrative cases that, in addition, will provide details of the administration, dosage, and side-effects.

Case 1.—A 57-year-old man had idiopathic paralysis agitans. In 1949 he began to experience some difficulty in writing. This was followed by tremor and rigidity of the right arm and leg, which rapidly spread to involve the trunk and left limbs. In addition there was marked akinesia; frozen facies; labored speech; and contractures in the spine, neck, and limbs. He could not dress or feed himself without assistance, and when he was placed on his feet, his gait was propulsive and he tended to fall. He became totally disabled for work in 1955. Therapy with a variety of drugs, including trihexyphenidyl, benztropine methanesulfonate, cycrimine, and orphenadrine, in turn, had been tried, but his tolerance was poor and he rejected all medicaments on complaint of dryness and mental fogginess. For the past three years he had relied almost entirely on physiotherapy for relief. In June, 1958, therapy was started with a 100-mg. capsule of chlorphenoxamine, three times daily, and when seen a month later he showed remarkable change. His mind was sharper, his movements freer, and his gait steadier, and he was able to smile and talk. There was a release of automatic movement so that he was able to get out of a chair with ease and spontaneity. He then began to take two 50-mg. tablets three times a day and has continued to the present in a more vigorous, active, and happier state than he has been in many years. There have been no side-reactions.

This man could not tolerate standard agents and yet found it possible to accept large doses of chlorphenoxamine with benefit and without a single complaint of side-reactions. A euphoric element appeared among the effects in this as in many other cases. It is difficult to be certain whether this is a direct action of the drug or whether it is secondary to the physical improvement. It would seem to be primary.

Case 2.—A 55-year-old woman had suffered from postencephalitic paralysis agitans since 1925, when drowsiness and tremor of the right hand appeared. During succeeding years came rigidity of the trunk and right limbs, sialorrhea, drooling, and monotone speech. Vaccines were tried without avail and, later, massive doses of atropine and Bellabulgara. More recently, trihexyphenidyl was used, but by 1956 contractures appeared in the neck, spine, and legs, and the body became bent. Rigidity and akinesia progressed to a point where the patient was barely able to get out of a chair, and her gait became propulsive and stumbling. Other preparations were tried, among them benztropine methanesulfonate, cycrimine, and orphenadrine, with only temporary relief, and the patient returned to therapy with trihexyphenidyl. In April, 1958, 50 mg. of chlorphenoxamine, three times daily, was added to the 10 mg. of trihexyphenidyl, three times daily. The effect on tremor, rigidity, akinesia, and drowsiness was dramatic. Her mind sharpened, she moved with greater speed and freedom, and her speech became clearer. She was able to get in and out of bed; before she had been unable to do so. She felt stronger and happier. In August she ran out of her allotment of chlorphenoxamine and again became rigid, with her body bent, and in an effort to get out of bed she fell and injured her side and head. On continuing therapy with chlorphenoxamine, she regained the original improvement and has continued to do well.

The above case illustrates the manifold actions of the new compound, even against tremor. It especially points up the fact that when medication is discontinued, all benefits cease; hence the need for continuous medical supervision and treatment of patients with paralysis agitans.

Case 3.—A 60-year-old man suffered from idiopathic paralysis agitans of eight years' duration. His chief problem was tremor of the left arm, with increasing rigidity in the left limbs. He was sensitive to all medicaments, and even small doses caused nausea and dryness and made him feel "dopey" and weak. In February, 1958, therapy with 50 mg. of chlorphenoxamine was tried with 1 mg. of benztropine methanesulfonate, twice daily. After a week he complained of indigestion and an upset stomach. The chlorphenoxamine therapy was discontinued. A month later it was tried without benztropine methanesulfonate and the effect was "marvelous." He became more relaxed and stronger, and his appetite improved. "If I could only stay this way for the rest of my life" was his comment. He has taken chlorphenoxamine, 50 mg. three times a day, for the past seven months and there have been no further complaints of indigestion.

The above case shows the lasting good effects of chlorphenoxamine and indicates that it can be used alone to better advantage in some sensitive patients than when combined with other compounds.

An instance of failure and a common problem are illustrated in case 4.

Case 4.—A 63-year-old man had bursitis of the left shoulder three years ago; it improved with x-ray treatment. Shortly after came a general slowing down of the body and a shuffling, stumbling gait. His left arm, and later the right arm, became tightened and drawn upward across the abdomen. He was given a diagnosis of arteriosclerotic form of paralysis agitans. He was treated with 2 mg. of trihexyphenidyl, three times daily; he discontinued this therapy after a week because of dryness and mental confusion. Later therapy with a combination of 1.25 mg. cycrimine and 25 mg. of phenindamine (Thephorin), three times daily, was tried, which after a favorable interval had to be abandoned because of complaints of "dopiness," dryness, and blurring of vision. He returned to therapy with one tablet of trihexyphenidyl a day. By this time tremor appeared in his arms, and he was placed, in turn, on therapy with ethopropazine, diphenhydramine, and hyoscine, to all of which he was sensitive. In August, 1958, he experienced cramps in his legs. Benztropine therapy was tried and had to be discontinued because of mental confusion. He was thereupon given 50 mg. of chlorphenoxamine, three times daily, after meals. He reported that the first tablet made him very drowsy and that the second tablet put him to sleep "for two days" so that he could not work in his candy store. He returned to therapy with one tablet of trihexyphenidyl per day, which could not possibly combat his advanced symptoms.

Here we could see neurotic and hypersensitive components in the personality operating as severe obstacles to better therapy.

Side-Reactions

There was not a single instance of dangerous or toxic effects among the 161 patients with paralysis agitans under treatment with chlorphenoxamine. Such side-effects as occurred from its use were of minimal degree and of no greater frequency than those encountered with standard agents. Ten patients complained of indigestion; eight, drowsiness; six, dryness of the mouth; four, nausea; four, dizziness; and two, anorexia. A total number of 28 patients (17%) offered a total of 34 complaints. Chief among the complaints were indigestion, drowsiness, and dryness of the mouth. The indigestion was largely corrected by having the patients take the medicament after meals and with milk instead of water.

It is of interest that no objective pupillary changes occurred, even among patients who were using as much as 600 mg. of chlorphenoxamine a day; nor was there a single complaint of blurring of vision. On this basis, chlorphenoxamine may be considered an ideal drug to use in patients with paralysis agitans who also suffer from glaucoma.

Comment

We stand in great need of drugs that will successfully counteract akinesia, adynamia, mental sluggishness, and lack of mobility in patients with paralysis agitans. In fact, some neurosurgeons have reached a decision not to operate in such situations, because even after reduction or elimination of rigidity and tremor the patients are almost as disabled as they were before the operation. While we possess several drugs that can combat these symptoms, it so happens that orphenadrine has a tendency to lose its good effects rather rapidly in some patients; dextro amphetamine (Dexedrine) sulfate often causes excitation and disturbing palpitations; methylphenidate (Ritalin) hydrochloride helps an occasional patient only when used in large doses of 20 or 40 mg.; and amphetamine (Benzedrine) sulfate causes cardiocirculatory reactions in the older patients.

In this setting, chlorphenoxamine has proved a valuable addition to current remedies because it exerts a gentle, stimulating action that continues month after month in a high percentage of patients in whom it proves effective. It is especially good to use in patients in whom the effects of orphenadrine have worn off. It affords energy, greater freedom of motion, more strength of body, and a general feeling of well-being that lasts throughout the day. True, it does not perform as would be desired in all cases, but then no drug has yet been discovered that is effective in 100% of patients with paralysis agitans. Experience has shown that if a new drug provides 30% of patients greater benefits than they were able to obtain from available compounds, it has clinical merit. Because chlorphenoxamine is a nontoxic compound and because it affords relief to 53% of patients who were insufficiently helped by current remedies, it is a worthy addition to the armamentarium of preparations for paralysis agitans.

Summary and Conclusions

A new drug, chlorphenoxamine, has been shown by studies abroad and in our own series of 161 patients with paralysis agitans to be free of toxic effects. It has positive value in the treatment of the disease. It is especially effective against rigidity, akinesia, fatigue, depression, and weakness, but less against tremor. It provides the patient with more energy and strength, greater freedom of motion, and longer duration of activity than most current remedies. Increased tolerance is comparatively rare and does not appear before three to six months of use. The method of administration and posology are presented and illustrated by case records. The side-reactions are minimal. It is of little benefit in non-Parkinsonian extrapyramidal diseases. The findings indicate that chlorphenoxamine is a valuable addition to the armamentarium of drugs for use in patients with paralysis agitans. It can be used alone or with other agents, such as trihexyphenidyl (Artane) hydrochloride, cycrimine (Pagitane) hydrochloride, procyclidine hydrochloride (Kemadrin), benztropine (Cogentin) methanesulfonate, or ethopropazine (Parsidol) hydrochloride.

710 W. 168th St. (32).

The chlorphenoxamine used in this study was supplied by the Pitman-Moore Company, Division of Allied Laboratories, Inc., Indianapolis. It will be marketed under the trade name of Phenoxene.

CLINICAL NOTES

STATISTICAL METHOD FOR DETERMINATION OF OVULATION TIME IN WOMEN

Donald S. Murray, Ph.D., Philadelphia

The data developed by Sevag and Colton for their paper "Simple Chemical Method for the Determination of Ovulation Time in Women," which appears in this issue of THE JOURNAL, page 13, offer the opportunity to test the possibility of applying a simple technique of linear correlation to estimate the day of ovulation. The data studied were limited to normal full-term pregnancies where conception was achieved by therapeutic donor insemination. In addition, all patients having menstrual cycles of less than 23 or more than 34 days were eliminated from consideration. Data beyond these limits appeared to be sufficiently unusual as to warrant their exclusion from a study that seeks to determine whether any typical relation exists between the length of the menstrual cycle and the day of ovulation.

Average Length of Menstrual Cycle and Day of Ovulation for Sixty-seven Women

	Average Length of Cycle in Days, No. of Women												
Day of Ovulation	23	24	25	26	27	28	29	30	31	32	33	34	Total
10			1	2									3
11			1	3	2	3		1					10
12	1		1	3	1	6	1	1		1			15
13					2	6	4	3		1	1	1	18
14						4	3	3	3	2		1	16
15									2			1	3
16							1				1		2
Total	1	0	3	8	5	19	9	8	5	4	2	3	67

Sixty-seven patients met the criteria concerning manner of conception and length of the menstrual cycle. These patients had a mean cycle length of 28.7 days and a mean day of conception of 12.8 days as compared with 29.0 days and 12.7 days, respectively, for all cases in which conception took place. The table presents the cases of these patients, classified on the basis of the average length of the menstrual cycle and the day on which conception occurred.

With the average length of the menstrual cycle as the independent variable the following measures are obtained: regression equation: $Y_c=2.2+0.37X$; standard error of estimate, 1.1; and coefficient of correlation, 0.63. In using this regression equation the average length of the menstrual cycle is substituted for X, and the Y_c value obtained indicates the likely day of ovulation. It may be expected that approximately two-thirds of the cases will lie within a range of ± 1 standard error of estimate. The coefficient of correlation, which in this case differs significantly from zero, is an indication of the relationship or association between the average length of the cycle and the day of ovulation.

To illustrate the use of these measures let it be assumed that a woman has an average menstrual cycle of 30 days. Substituting this for X in the equation gives day 13.3 for Y_c, i. e., ovulation is most likely to occur during the 13th day. The standard error of estimate indicates that in approximately two-thirds of the cases ovulation would occur for such a person not earlier than day 12.2 nor later than day 14.4.

From these statistical measures several observations can be made. First, the data tend to confirm the findings of Sevag and Colton that ovulation (as judged by successful inseminations) occurs between the 10th and 15th day for nearly all cases regardless of the length of the menstrual cycle. Using the extremes of length of the cycle for the 67 cases studied, 23 days and 34 days, the range of the day of ovulation runs from 10.7 to 14.8, i. e., essentially the same results as the Sevag-Colton paper indicate. Second, the amount of change in the day of ovulation for a one-day change in the average length of the menstrual cycle is slightly more than one-third of a day.

Meaning of Statistical Measures

The value of the regression equation that has been developed lies in the fact that it permits one to determine the probable date of ovulation when

---

the chemical procedures described in the Sevag-Colton article are not available. Although in their article they indicate that ovulation seems most likely to occur between cycle days 10 and 15, the use of the equation permits a more critical determination that takes account of the length of the menstrual cycle, e. g., for a 24-day cycle ovulation can be expected on day 11.1, whereas for a 32-day cycle the day of ovulation might be expected to be 14. For the person interested in determining dates in the absence of the availability of chemical tests such variation could be of significance.

FEBRILE REACTION TO PROCAINAMIDE THERAPY

Edgar F. Luton, M.D., Memphis, Tenn.

Since procainamide (Pronestyl) was introduced in 1950, four instances of febrile reactions to this drug have been reported. Review of these and details of another well-documented case are presented in order to delineate the characteristics of the reaction and the type of investigation necessary to establish the diagnosis with a reasonable degree of accuracy.

In each of these cases, the appearance of the febrile reaction was rather prompt. It occurred within the first 24 hours after administration of the drug and it disappeared within 24 hours after the drug therapy was discontinued. The appearance of fever and general malaise in patients with recent myocardial infarctions in two of the cases reported led to investigation for cause of the fever other than the presence of a febrile reaction due to the drug. This is likely to be the course taken under circumstances that were present at that time, and, if it is not borne in mind that febrile reactions to procainamide can occur, such investigations may be extensive and futile. When discontinuation of the drug therapy is followed by clearing of the febrile reaction, one cannot assume that this is proof of a febrile allergic drug reaction. After the symptoms have been reproduced on administration of the drug and seen to disappear on discontinuation of administration for a total of three occasions, it is reasonable to conclude that one is dealing with an allergic febrile reaction. Myocardial infarction is a serious illness and complications deserve serious consideration. The clinical picture and investigation of such a reaction to procainamide therapy are illustrated in the following case report.

Report of a Case

A 61-year-old male was admitted to the hospital on Feb. 15, 1957, because of progressive dyspnea of about two months' duration. He had been hospitalized in January, 1952, with an acute myocardial infarction. During that hospitalization he had numerous premature ventricular contractions and was given procainamide, 500 mg. every four hours, or every six hours, for a period of four weeks. The drug therapy was discontinued after four weeks. He had been hospitalized later because of symptoms of angina pectoris and was found to have a low cardiac reserve.

On admission, physical examination revealed moist inspiratory basal rales, moderate cardiac enlargement, and a trace of ankle edema. He was observed to have frequent premature contractions, which on electrocardiographic study were demonstrated to be ventricular premature contractions. The signs and symptoms of congestive heart failure disappeared on bed rest, a low-sodium diet, and an occasional injection of meralluride (Mercuhydrin). On March 6, 1957, procainamide therapy, 250 mg. every six hours, was begun because of the premature ventricular contractions. On March 7, he had a chill and for the next 11 days felt poor generally. He complained of weakness, anorexia, general malaise, and febrile sensations, and he had run an elevation of temperature almost constantly. On March 18, the drug therapy was discontinued and within 24 hours the patient felt much better. His appetite improved, and he no longer complained of generalized aching and sensations of fever. His temperature became normal.

On three subsequent occasions the patient was given procainamide with definite febrile responses beginning about 12 hours after the first dose. The procainamide was given in doses of 250 mg. every four hours for a variable number of times. When he was given only 250 mg. for one dose, he did not have any reaction. If it were given for two doses, he would have a chill and fever. Dummy capsules of the same appearance but containing lactose did not give a similar reaction. To document the febrile

---

From the Medical Service of the Veterans Administration Medical Teaching Group Hospital (Kennedy).

reaction clearly, the patient's temperature was taken every four hours day and night. During this time it ranged between 96.2 and 98.0 F (35.7 and 36.7 C). No change in temperature or symptoms appeared on administration of the dummy capsules, but when he was given procainamide, 250 mg., at 8 a. m., and this was repeated at noon, a chill was experienced at about 9 p. m. His temperature was 101 F (38.3 C) at 12 midnight, 100 F (37.8 C) at 4 a. m., and normal at 8 a. m. and remained normal for the next two days.

The patient declared that the first sensation of the reaction was a tingling and generalized feeling of nervousness, followed by general malaise and nausea. At the same time he would develop a definite diuresis. When he was observed at these times he appeared to have peripheral vasoconstriction. His skin was pale and moist. Chill and fever then appeared. He had no diarrhea and no vomiting; his blood cell count did not change. Procainamide did not have any appreciable effect on the premature ventricular contractions. Results of a patch test were negative to procainamide. Further skin testing was not done, since it is well known that skin tests are not reliable in drug reactions of this type.

Comment

The first report of febrile reactions to procainamide was by Leibowitz[1] in 1951. He reported the case of a 48-year-old businessman with episodes of tachycardia not responding to quinidine. The patient was given 500 mg. of procainamide four times daily, and within a week he reported experiencing weakness and sweating during the day and shaking chills and fever in the evenings. He stopped taking the drug and suffered no further chills and fever until he was advised to reinstate the medication and within 24 hours experienced another shaking chill. Procainamide administration was discontinued and within 24 hours his temperature was normal. Attempts to induce him to take it again were unsuccessful.

In August, 1952, two cases of febrile reaction to procainamide given orally because of premature contractions were reported.[2] One of the patients had had a recent posterior myocardial infarction and was on anticoagulant and procainamide therapy.[2a] An unusually high temperature was noted for five days, and anticoagulant and procainamide therapy was discontinued with the result that within 24 hours the temperature was normal. Improvement in the patient was said to be immediate and dramatic. Aching and malaise, as well as nausea and apprehension, had been experienced, and these were no longer present within 24 hours after the drug therapy was interrupted. Two days later, the patient was given 250 mg. of procainamide at 10 a. m. and by 4 p. m. that afternoon was uncomfortable and irritable and had a temperature of 104 F (40 C). A total of five doses of 250 mg. of procainamide every four hours was given and then the therapy was discontinued. The next day the patient felt normal again and remained so for five days. The therapy was then resumed for the third time, and after the third dose she again developed fever with a maculopapular itching rash. After discontinuing administration of the drug, symptoms disappeared promptly.

The second patient[2b] was a 53-year-old male with hypertension of 20 years' duration who suddenly developed substernal pain and was found to have an acute anteroseptal infarction pattern on an electrocardiogram. He was immediately given a dose of 1.5 Gm. of procainamide orally because of premature contractions. This was followed by 250 mg. of the drug every four hours. After the third dose the patient developed a generalized maculopapular erythematous rash with severe itching, nasal congestion, slight generalized lymphadenopathy and a temperature of 102 F (38.89 C). Procainamide therapy was discontinued and diphenhydramine (Benadryl) given every four hours. His symptoms disappeared within 24 hours. The patient was receiving other medicines at the time of the reaction so he was given procainamide three months later. After the fourth dose of 250 mg. every four hours, the same reaction occurred, and the therapy was discontinued. Results of a patch test were negative.

In December, 1952, McGarry[3] reported the case of a 57-year-old man with an acute myocardial infarction who, after being placed on therapy with 500 mg. of procainamide every four hours from the 5th day after infarction until the 20th day, showed a temperature range between 101 and 103 F (38.33 and 39.44 C). After the procainamide therapy was discontinued there was prompt defervescence and striking subjective improvement. After the patient had been feeling well for 72 hours, a test dose of 500 mg. of procainamide, given orally, produced a recurrence of fever with nausea, headache, and joint pains which subsided within eight hours.

Procainamide was introduced in 1950 as a treatment for cardiac arrhythmias, and in the subsequent years it has become widely used because it has been effective and relatively nontoxic. It was developed as a substitute for a procaine which had previously been shown to have an antiarrhythmic myocardial action but had the undesirable properties of being short in duration of action and stimulatory to the central nervous system. Procainamide has rather rapid and complete gastrointestinal absorption and is slowly metabolized when compared with procaine. Untoward side-effects, such as anorexia, or nausea and vomiting, as well as a tendency to sometimes produce a hypotensive state, are features of administration of this drug that are well known. Among the rather rare side-effects of administration of procainamide are ventricular fibrillation, ventricular tachycardia, and allergic reactions. Included in the allergic type of reactions thus far reported are rashes, asthma, and fever. Agranulocytosis, which has been reported, might also be an allergic reaction.

THE FERTILITY TESTOR

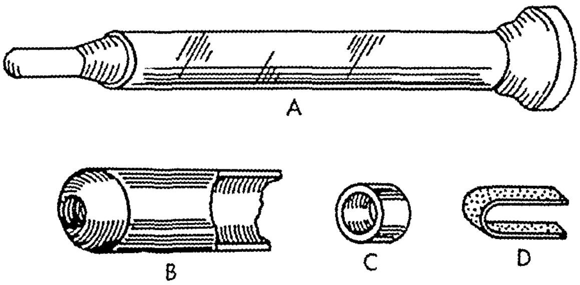
Joseph B. Doyle, M.D.
and
Frank J. Ewers, M.D., Boston

In previous issues of The Journal it has been demonstrated that the fertile period of the menstrual cycle can be concurrently identified by detecting a rise in the glucose content of the cervical mucous cascade utilizing Tes-Tape (paper impregnated with the enzyme, glucose oxidase) on either a swab[1] or a tampon.[2] Gluconic acid, the end-product, is converted to hydrogen peroxidase which, in the presence of traces of orthotolidine, produces a blue color that can be seen as shades of green when viewed on a yellow strip. The glucose present in the cervical mucus may be partly from aspirated liquor folliculi, but most of it is from glycolysis within the cervix itself.[2] A recent positive test from the cervix and cul-de-sac fluid of a patient who had previously undergone supracervical hysterectomy and bilateral salpingectomy without oophorectomy demands such a conclusion.

Both techniques required further improvement to minimize the contact of the Tes-Tape with glucose originating from the vagina itself. To this end we have successfully used a simple, inexpensive, permanent plastic syringe, like the Fertility Testor (see figure) designed by one of us. (F. J. E.). This consists of a narrow 6-in. hollow barrel perforated at its rounded tip by an orifice through which the strip of Tes-Tape may be thrust into contact with the cervix with the beveled nub of the plunger to which it has been affixed by a small plastic ring.

Method

It is preferable for the physician to introduce the syringe through a vaginal speculum in his office in order to acquaint the patient with the sensation of contact with the cervix. Care must be taken to introduce it into the vagina grasped like a pen, with the plunger inserted only halfway down the barrel, thus eliminating contact of the Tes-Tape strip with the vaginal secretions. Since at ovulation time the cervical mucus is a cascade 2 to 10 times its usual volume and is less viscid and more watery, the glucose-laden mucus bathes the posterior fornix



Fertility Testor. To use, (1) take apart by removing plunger, *A*, from barrel, *B*, then (2) remove ring, *C*, from tip of plunger, (3) measure strip of tape, *D*, from roll to cover entire narrowed tip of plunger, and (4) cover tip of plunger with strip of tape. (5) Hold tape in place by putting ring over tape and tip of plunger, push down ring until it fits snugly (no other fixative is required), and (6) replace plunger halfway into barrel.

From the departments of gynecology and obstetrics, St. Elizabeth's and St. Margaret's hospitals.

of the vagina regardless of the direction of the external orifice of the cervix. After the barrel strikes the posterior fornix the plunger is gently pressed to force the tape through the opening at the tip of the barrel. After three minutes of deep cervical contact the patient is advised to withdraw the plunger and its affixed Tes-Tape through the barrel, thus avoiding contact of the tape with the vagina. Within three minutes after withdrawal the color of the Tes-Tape is compared with the blocks of three shades of green on the side of the Tes-Tape dispenser.

Interpretation.—Any color change appearing along even the sides of the Tes-Tape is significant, for by capillary attraction the glucose solution gravitates to the juncture with the dry Tes-Tape. If no sugar is present it remains yellow; a quantity less than 0.1% will result in pale green (+); and a quantity of glucose over 0.25% will produce a deep green (++) color. The color change is usually best seen in that portion of the Tes-Tape under the plastic ring. The deep green, indicative of a high glucose value, usually occurs synchronously with ovulation.[3] We find it useful to have the patient record her basal oral temperature on a chart each morning and the result of her glucose test below the temperature recording each evening prior to any coitus on every day of the cycle after the cessation of menstrual flow. If the patient must be up during the night, the temperature may be unreliable; but the glucose test is unaffected.

With such a concurrent indicator, the known variability of the relation of ovulation to the basal thermal shift—between two days before, the day of the thermal shift, and two days after it—can be more accurately checked. Actually, the appearance of a + result of the test, indicating a 0.1% glucose level, and the first ++ result, indicating a 0.25 level, usually precede the shift in basal temperature by a day or two. Occasionally the maximal glucose present does not exceed 0.1% (+), which is still significant and may represent the prevention of follicular fluid from reaching the cervix by neurogenic uterotubal spasm.[2]

Fertility Use.—The infertile couple will utilize for first coitus the day of the first + result, since sperm will survive until the day of the first ++ result. Usually the first ++ reaction occurs synchronously with rupture of the follicles as confirmed during culdotomy by simultaneous biopsies of the endometrium and the ovarian follicles or early corpora hemorrhagica (25 cases). A negative test result was seen on three other occasions when there was no ovulation. Similar accuracy of the Tes-Tape glucose reaction has been reported by Birnberg,[1] who obtained 20 successful therapeutic inseminations out of 27 attempts on the first day of the ++ reaction with a single insemination. Though small in numbers these reports suggest valuable consistency and utility of the test.

Its greatest usefulness appears to be for those patients with infertile husbands whose thermal shifts were prolonged, e. g., from day 7 to day 24. Prompt conception followed isolated coitus on day 11 when during the preceding month the glucose pattern was negative to day 9, followed by a + reaction on day 10, a ++ reaction on days 11 and 12, a + reaction on day 13, and negative through the rest of the cycle. An occasional patient may show a ++ reaction all month. However, if preceded by a hot-water douche and drying of the vagina by a tampon, more consistent readings may be obtained. For these patients, and for diabetics, the test may be of limited value. Naturally, use of this method can be no guarantee that pregnancy will or will not occur, since 25% of ova are abnormal and the conceptus does not necessarily nidate properly.

Use in Postponing Pregnancy—Concurrent Ovulation Rhythm Technique.—The highly fertile couple desiring for medical reasons to avoid pregnancy must be advised not to have coitus during the month until four days after the few days of positive glucose tests have ceased. Since one patient had positive glucose tests for four successive months on days 11 and 17, respectively, this test may aid those women who ovulate more than once a month to practice periodic continence (rhythm theory) more successfully by avoiding coitus until after any such secondary positive test.

Further confirmatory studies of the glucose content of the liquor folliculi[2] and tubal and uterine fluids and their relation to the fern pattern, sperm survival, and spinnbarkeit of cervical secretion are in progress.

Summary

An accurate calculation of fertility time can be made by simultaneous use of basal temperature charts and cervical glucose determinations made with use of an inexpensive permanent plastic syringe-like instrument, the "Fertility Testor," which permits the introduction of a strip of Tes-Tape (paper impregnated with the enzyme, glucose oxidase) for assay of glucose from the cervical mucous cascade at ovulation time, without interference from vaginal secretion.

520 Commonwealth Ave. (10) (Dr. Doyle).

The Fertility Testor is available on prescription only from physicians from the Fertility Testor Company, Ottawa, Ill.

COMMITTEE ON MEDICOLEGAL PROBLEMS

CHEMICAL TESTING PROCEDURES FOR THE DETERMINATION OF ETHYL ALCOHOL

Theodore E. Friedemann, Ph.D., Denver
and
Kurt M. Dubowski, Ph.D., Des Moines, Iowa

This report is chapter 5 from a manual, being prepared by the Committee on Medicolegal Problems, dealing with medical and legal procedures involved in the use of chemical tests for intoxication.

Chemical analysis of the blood, urine, saliva, or breath gives the following information: first, it establishes the presence or absence of alcohol in the body; second, it determines the concentration in body fluids and tissues; third, it permits calculation of the approximate total quantity of alcohol in the body; and, finally, it furnishes the basis for calculation of the approximate volume of alcoholic liquor or beverage which may have been ingested within some hours prior to collection of the sample. Thus, chemical analysis not only furnishes objective data on the presence of alcohol in the body but also checks the reliability of statements with respect to ingestion of alcohol.

Observations on the subject's physical and mental state and the results of chemical tests together constitute the data on which judgment of the degree of intoxication is made.

Of the more than 200 analytical methods for ethyl alcohol, the majority have many common features with respect to such unit operations and unit processes as distillation, oxidation, and determination of the degree of oxidation. The majority depend on two important properties of alcohol: volatility and oxidizability. All methods, however, depend on one or more physical or chemical properties of alcohol, and all use one or more basic unit operations and unit processes for differentiation of alcohol from other compounds and for determination of ethanol identity and quantity. The differences between methods are largely in the combinations of the unit operations and in the details within each unit operation. The methods differ greatly in simplicity, speed, accuracy, specificity, sensitivity, and applicable range of concentrations. They therefore vary considerably in their adaptability to clinical and forensic problems.

The existing methods, although large in number, fall into two categories: laboratory tests, applied principally to the analysis of blood, urine, and saliva; and on-the-spot tests, applied to the analysis of exhaled breath. Both categories of methods require not only understanding of the chemical principles but also skill in the chemical and instrumental manipulations. The laboratory should be well planned and organized; the equipment must be adequate; the analyst should possess training and experience at least equivalent to that of the clinical laboratory technologist, and preferably be a professional analytical chemist; and over-all supervision (or frequent consultation) should be maintained by an experienced toxicologist, clinical biochemist, or pathologist.

Basic Principles of Chemical Tests

All methods for the determination of ethyl alcohol in biological materials include several common elements: (1) sampling, including collection of exhaled air, body fluid, or other constituent, and measurement of the aliquot to be analyzed; (2) separation of ethyl alcohol from the biological material of the sample aliquot; and (3) quantitation of the separated alcohol. Some alcohol methods, particularly those for forensic application, include a fourth step: identification of ethyl alcohol and/or any possible chemically interfering substances as sample components.

Sampling.—Careful sampling, preservation, and handling are fundamental to accuracy. The identity and integrity of the sample must be maintained from the time of collection until analysis. This aspect of laboratory tests is far more exacting and difficult than that of on-the-spot tests, in which samples of exhaled breath are collected and immediately analyzed, but not stored. However, this feature of the laboratory tests not only permits many analyses by the same method in the same

Army Medical Research and Nutrition Laboratory, Fitzsimons Army Hospital (Dr. Friedemann); Director of Chemistry, Iowa Methodist Hospital and Raymond Blank Memorial Hospital for Children, and Criminalist, state of Iowa, Department of Public Safety (Dr. Dubowski). Dr. Dubowski is now at the J. Hillis Miller Health Center, University of Florida, Gainesville.

laboratory, or redetermination by other methods, but also allows independent analysis in other laboratories.

Removal of Alcohol from Sample.—The techniques for removal of alcohol fall into three categories: diffusion-desiccation, aeration, and distillation. The latter includes simple distillation, steam distillation, and distillation under reduced pressure.

Diffusion-Desiccation.—The most widely known diffusion procedure is that of Widmark.[1] The sample is placed into a small glass cup which is suspended in a sealed flask containing oxidizing solution. In the Conway desiccation procedure, the apparatus consists of a covered cylindrical glass or porcelain dish with a center well. The sample is placed in the space surrounding the center well, which contains the oxidizing solution.

Aeration.—Aeration of the sample at room temperature and bubbling of the vapor through potassium dichromate and sulfuric acid solution or other oxidizing reagent has been used,[2] as has aeration at elevated temperatures, which shortens the required aeration time.[3]

Distillation.—Distillation of alcohol from the sample may be carried out with heat and evacuation or with steam.[4] The recovery of alcohol by these methods has not been as good as by simple distillation at atmospheric pressure; the apparatus for vacuum and steam distillation is more complicated, and the operation requires more attention and time. The recovery of alcohol by direct distillation at atmospheric pressure is quantitative, or nearly so; this procedure is therefore preferred.

Prevention of Foaming During Distillation.—Foaming is always encountered during distillation of untreated biological materials. It not only slows the rate of distillation but also may lead to considerable entrainment of impurities into the distillate. Precipitation of blood and tissue proteins eliminates foaming almost entirely.

Harger[5] precipitates the proteins by sodium tungstate and dilute sulfuric acid; an aliquot of the protein-free filtrate is then distilled. Trichloroacetic acid and other precipitants have been similarly used. Friedemann[6] has obtained an efficient precipitation by adding an acid mercuric sulfate–copper sulfate–ferric sulfate reagent to the sample, followed by adding calcium hydroxide suspension. The reagent removes sugars, primary and secondary amines, amino acids and proteins, sulfhydryl compounds, ketones, ketoacids, aldehydes, and many phenols. The filtrate from saliva may be analyzed directly without distillation.[6]

Direct distillation of the sample without previous precipitation of protein and filtration is preferred by most authors. The precipitant or antifoaming agent is added to the sample in the distilling flask. Picric acid is the oldest and perhaps most widely used antifoaming agent, but tartaric acid, both picric and tartaric acid, phosphoric acid, paraffin, mineral oil, and silicones have also been used.[7] The presence of high salt concentrations facilitates volatilization according to some analysts, who add large quantities of ammonium sulfate or sodium sulfate.

Tungstic acid and mercury salts are the most efficient precipitants and antifoaming agents, some analysts preferring the use of a combination of acid mercuric sulfate and tungstic acid, which permits rapid distillation of blood and urine samples without foaming.

Removing Interfering Substances from Distillates.—The most important volatile substances in forensic samples of blood and urine are organic acids, aldehydes, ketones, and phenolic compounds. Examples are formic, benzoic, and salicylic acids; formaldehyde and acetaldehyde (and paraldehyde, which readily decomposes to acetaldehyde when distilled with acid); acetone; and "carbolic acid" and menthol. The distillate may be treated with freshly precipitated silver oxide, which is added to the approximately neutral distillate and allowed to stand for some time before redistillation. For many years this has been a standard procedure for removing aldehydes and ketones. Silver oxide slowly oxidizes methyl and ethyl alcohols to the respective acids.

It has also been found that freshly precipitated mercuric oxide in approximately neutral solution efficiently removes aldehydes and ketones; during four or five hours' refluxing with the reagent, 3 to 5% of alcohol is lost. Greater quantities are lost at high alkali concentrations. Mercuric oxide has been similarly used. Some analysts recommend the addition of mercuric sulfate and an excess of calcium hydroxide suspension to the distillate. No loss of alcohol is noted at the approximately 0.08 *N* alkalinity of calcium hydroxide suspension.

Quantitative Determination of Separated Alcohol.—In all published alcohol methods quantitative determination of separated alcohol depends on one or more of the following analytical principles:

1. Isolation of ethyl alcohol and measurement of its mass or volume in pure form.
2. Determination of the physical properties of a distillate or vapor phase containing ethanol (e. g., by gas chromatography, interferometry, mass spectrometry, polarography, or measurement of specific gravity or refractive index.
3. Pyrogenic dehydration of ethanol to ethylene, followed by bromination, liberation of free iodine, and measurement of the latter.
4. Formation and estimation of iodine derivatives of ethanol (e. g., iodoform, ethyl iodide, etc.).
5. Conversion of ethanol to ethyl nitrate and measurement of hydrolysis of the latter by release of free iodine from potassium iodide.
6. Oxidation of ethanol to acetaldehyde and quantitation of the latter.

7. Enzymatic dehydrogenation of ethanol with alcohol dehydrogenase with simultaneous reduction of diphosphopyridine nucleotide (DPN) to dihydro-DPN, and measurement of the latter by ultraviolet spectrophotometry.

8. Oxidation of ethanol with a known standard oxidizing reagent to a predetermined color endpoint.

9. Oxidation of ethanol to acetic acid with an excess of oxidizing reagent and determination of the ethanol oxidized from the quantity of oxidizing reagent reduced as determined from the quantity of reaction products resulting, or by measurement of the excess of oxidizing agent remaining (by titration, photometry, spectrophotometry, visual color comparison, etc.).

10. Oxidation of ethanol to acetic acid and titration of the latter.

The last three procedures are employed most widely at present and therefore will be discussed briefly.

Oxidation of Isolated Alcohol: Choice of Oxidizing Agent.—Potassium permanganate, iodine pentoxide, and potassium dichromate are the most commonly used oxidizing agents.[8] Permanganate oxidation in acid solution is used in the Drunkometer on-the-spot test. Complete oxidation is accomplished rapidly. The reaction is sensitive, reproducible, and not noticeably affected by the small quantities of volatile substances other than alcohol which may be present in the exhaled breath of normal and intoxicated persons.

On the other hand, permanganate oxidation in alkaline solution is not specific for alcohol, yielding oxalic acid and carbon dioxide with alcohols, aldehydes, acetone, and other readily oxidizable substances. After alkaline oxidation, the solution may be acidified, which further oxidizes the oxalic acid to carbon dioxide. The residual permanganate is determined by various methods. The procedure is quite specific for alcohol if preceded by distillation from tungstate and acid mercuric sulfate and by redistillation from mercuric sulfate and lime, which removes (see above) most of the interfering classes of compounds.

Oxidation by iodine pentoxide has also been used.[9] The oxidation, which is carried out at high temperature, requires careful regulation and produces carbon dioxide and water. It is similarly complete for many other substances and therefore is not specific for alcohol. The oxidation is highly sensitive and reproducible. It is applicable only to determination of alcohol in vapors, and it is the basis for the Alcometer on-the-spot test for alcohol in breath.

The majority of methods employ oxidation by potassium dichromate in sulfuric acid solution. However, this oxidation has also been carried out in nitric acid and in phosphoric acid. The relative rates and the degree of oxidation of alcohol and other organic compounds (and therefore the specificity for ethyl alcohol) are affected by acid concentration and temperature.

At concentrations above 20 *N*, sulfuric acid (concentrated sulfuric acid has about 36 *N* titratable acid) dichromate yields acetic acid from ethyl alcohol, which is further oxidized to carbon dioxide and water. The greater the acidity the greater the rate, until, in concentrated acid, the complete oxidation to carbon dioxide is rapidly accomplished. Twelve oxidizing equivalents are used per mole of ethyl alcohol. In concentrated acid most other organic compounds are also oxidized quantitatively. Thus, the dichromate oxidation, although possessing maximal sensitivity, is nonspecific at high acid concentrations.

As the sulfuric acid concentration is decreased below 20 *N*, the interfering effect of many volatile substances like acetone, ether, and chloroform becomes negligible. Thus, ethyl alcohol is oxidized quantitatively to acetic acid by dichromate at 18 *N* acidity. The reaction has high specificity but is slower and only one-third as sensitive as in concentrated acid solution.

Oxidation of Isolated Alcohol: Colorimetry, Spectrophotometry, and Titrimetry.—The final step in all oxidative methods is a measurement by either chemical or instrumental means. In the majority of titrimetric methods the oxidation is carried out with excess dichromate, followed by determination of the residual dichromate by various methods. Some add potassium iodide and titrate the liberated iodine with standard sodium thiosulfate solution. Direct titration of the excess dichromate may also be done with potassium ferrocyanide in the presence of diphenylamine or with standard ferrous sulfate solution using such indicators as *o*-phenanthroline. The color of the reaction mixture after oxidation may be compared visually with known standards or measured photometrically.

In some of the earliest chemical methods, the volatile acidity was determined by distillation and subsequent titration by standard alkali. Aliphatic alcohols, such as ethyl alcohol, produce the respective fatty acids. Thus ethyl, propyl, and butyl alcohols produce acetic, propionic, and butyric acids respectively. Each of these acids has a characteristic rate of distillation. Each also has a characteristic distribution between water and various solvents. From the titration of total volatile acidity and the observed distribution, the respective alcohol may be identified and determined quantitatively.[10]

Sampling for Laboratory Tests

Choice of Specimen Materials.—The source, type, and quantity of specimen for alcohol determination depends on such practical considerations as availability of persons legally and technically qualified to obtain various types of samples, possible necessity for procuring specimens in the field, available laboratory facilities, maximum time allowable for rendition of reports, and the desirability of minimizing the interval between the event in issue and the sampling time. Since alcoholic influence, in those states having statutory definitions, is expressed in terms of the concentration of ethyl alcohol in the blood, and since adequate correlations have been established between degrees of alcoholic influence and blood alcohol concentrations, it seems most direct and acceptable to analyze blood specimens, when possible. The blood alcohol concentration may be determined indirectly by analysis of any other body tissue or of exhaled air, using the known relations of distribution of alcohol between blood and tissues and between blood and alveolar air.

In practice, alcohol analyses are conducted on blood, breath, cerebrospinal fluid, saliva, tissues, and urine. When use of blood as a specimen material is impossible or undesirable, breath or urine specimens are most frequently employed for analysis, each having certain advantages and shortcomings. Thus, obtaining urine specimens from female subjects requires separate facilities and possibly, for forensic purposes, a female attendant able to identify the specimen as to its origin, noncontamination, or nondilution. Breath specimens are not readily collectible in duplicate or in sufficient quantity for later separate independent analyses by systems other than the Intoximeter (which makes such duplicate sampling a relatively expensive procedure) and generally must be analyzed immediately after collection in order to obtain reliable results. In dead persons, it may be difficult to obtain any specimen material, blood usually being the most readily and consistently available.

A number of technical problems must be considered in the use of blood specimens for routine alcohol determinations. During the early stage of alcohol absorption, the concentration of alcohol in arterial and venous blood may vary slightly. It has been suggested that only analysis of peripheral venous blood form the basis of precise interpretations; peripheral venous blood is probably also easiest to obtain in adequate quantities. Capillary blood, properly collected to avoid errors of sampling such as evaporation and dilution with tissue exudate, is also satisfactory, and the results of analysis approach those of arterial blood. Generally, the distribution or concentration of alcohol in the body fluids and tissues at equilibrium is in proportion to the water content.[11] The alcohol content of serum or plasma is about 10% higher than that of whole blood, in accordance with the water content of the body fluids. In any large-scale testing program occasional blood specimens are received which are partially clotted through use of ineffective anticoagulants or faulty sampling technique. Such clotted specimens can be analyzed without difficulty after homogenization.

Analysis of urine is used by many law enforcement agencies and clinical laboratories for the indirect determination of blood alcohol. Aside from the practical problem of collection facilities, two special technical considerations exist: the first is the relation between the level of alcohol in the venous blood and in the ureteral urine; the second is the relation between the alcohol content of the venous blood and of the urine present in the bladder at the time of collection of both, since any single random urine specimen represents a pooled ureteral urine sample, possibly further altered to some extent by alcohol diffusion through the bladder mucosa.[12]

Urine contains about 1.30 times as much alcohol as venous blood.[12] Most valid sampling systems recommend that the bladder be emptied and that one-half hour later the subject again be requested to void. The second sample is analyzed and the result, divided by 1.30, is taken as the concentration of alcohol in the venous blood at the time the test was made.[13] Our recommended routine is to collect two urine specimens at precisely known intervals of from 30 to 45 minutes after an initial complete emptying of the bladder, analyzing both later specimens in order to determine whether the subject's blood alcohol level, if any, was increasing or decreasing during the sampling period.

In estimating blood alcohol levels from urine analysis, one must realize that the levels in the first, second, and later specimens after initial emptying of the bladder represent an average of an infinite number of instantaneous ureteral urine alcohol levels during the entire secretion period of that specimen. Consequently, the blood alcohol level calculated by use of the distribution ratio of 1.30:1 is the blood alcohol concentration at a time midway between the beginning and the end of the collection period in the bladder and not the blood level at the time of voiding. All of these procedures assume that the bladder is emptied completely each time and that no residual urine is retained.

Postmortem Specimens.—In the collection of postmortem specimens, precautions must be taken to prevent contamination of the samples and to minimize changes of the alcohol level after their removal from the body. Enzymatic oxidation of alcohol to acetic acid can and does occur to some extent in the liver both before and after its removal from the body.[14] Alcohol can also be oxidized to acetaldehyde and acetic acid in vitro by brain, kidney, heart, and other tissues.[15] Since the oxidation is an enzymatic process, it can be minimized in vitro by effective refrigeration, preferably freezing at -20 C, which also tends to minimize putrefaction of tissue with attendant bacterial and fungal neoformation of alcohol and other volatile organic substances.[16] On the whole, these changes are small.

It is of considerable advantage to collect several different body materials in order to be able to estimate the stage of alcohol absorption existing at the time of death. Thus analyses of postmortem urine and blood yield considerably more information than either analysis alone. If the alcohol level in the urine exceeds that of the blood by more than 30%, assuming that both analytical results represent the actual levels at the time of death, it is obvious that a blood alcohol level existed at some time prior to death greater than either the urine or blood concentrations found post mortem and that the subject at the time of death was probably in the postabsorptive state with respect to the ingested alcohol. Conversely, if the postmortem blood alcohol level equals or exceeds that of the urine, the subject probably died in the absorptive phase and, therefore, probably within a few hours of the time of alcohol ingestion, which can frequently be fixed with some accuracy.[17] The possible import of such conclusions on explaining the cause, manner, and circumstances of death makes it advisable to collect two or more different body materials for postmortem alcohol determination.

The recommended routine is to collect adequate postmortem blood and bladder urine specimens whenever obtainable and to collect brain tissue and cerebrospinal fluid if those are available, as the next choice. Other tissues, such as liver and kidney, are less desirable but usable.

All postmortem body materials must be obtained prior to the start of any embalming procedure. Embalming fluids always contain considerable quantities of formaldehyde and methyl alcohol as well as other volatile substances, the presence of which in sample materials greatly complicates the analysis of ethyl alcohol; they may contain ethyl alcohol, which would render any postmortem alcohol analysis on embalmed tissues meaningless. Special precautions should be exercised against the frequent custom of collecting a postmortem blood specimen from the circulatory system effluent during arterial injection of embalming fluid.

The site of postmortem blood collection is of some importance, particularly in bodies which have been dead for some time, since it has been established that alcohol diffusion into the blood in the heart and the great vessels can occur from a large amount of alcohol in the stomach.[18] Because of the comparative ease with which adequate volumes of blood can be obtained, the heart and great vessels (aorta, pulmonary artery and vein, and vena cava) are the usual sites of collection, and uncontaminated specimens from these sources are satisfactory.[19] Adequate mixing of heart blood specimens before withdrawal is important; if it becomes necessary to withdraw heart blood from a body without autopsy, precautions against dilution of the blood with pleural or pericardial fluids should be employed. Adequate blood volumes for alcohol analysis can also be readily obtained post mortem from the femoral vein by raising the leg.

Size of Specimen.—With modern, sensitive analytical methods, smaller samples may be collected than formerly were required. Since alcohol is freely diffusible and is distributed in proportion to the water content, homogeneity of the sample is not a factor in the choice of sample size, as in the sampling of, say, food or coal for the determination of total nitrogen or calorie content. As reported by Freimuth and associates,[14b] there is no significant variation in alcohol concentration in different areas of the brain. The sample size is regulated by the quantities required for repeat determinations and for possible future rechecking of the analyses.

If necessary, 1 to 2 Gm. of tissue or 1 to 2 ml. of fluid can be analyzed readily. However, in practice, it is desirable to have larger quantities: 2 to 15 ml. of blood, cerebrospinal fluid, or saliva; 10 to 30 ml. of urine; and 10 to 50 Gm. of brain or other tissue. The sample should nearly fill the container.

Precautions During Collection.—Because of occasional claims in the literature that sterilization of the skin with alcohol can cause an apparent blood alcohol level of up to 0.25% w/w in abstaining subjects,[20] it is good practice to employ a nonalcoholic, nonvolatile skin antiseptic. Actually, controlled laboratory studies have consistently demonstrated that even excessive application of ethyl alcohol to the skin before venepuncture increases the existing blood alcohol level not more than 0.02%. Syringes and needles, of course, must be sterile, completely dry, and free of any trace of alcohol or other volatile substance. Consequently, alcohol, acetone, ether, or other volatile organic substances should not be used for sterilization or drying. Postmortem specimens should be collected with similar precautions except for sterility, and special care must be exercised to prevent contamination with any embalming fluid from needles, syringes, or containers.

Preservation.—From both the legal and analytical points of view, it is desirable to refrain as far as possible from adding preservatives or other substances to specimens. Tissue samples may be placed immediately after removal from the body into individual new, clean polyethylene freezer bags, which are sealed and placed into plastic-lined, cylindrical cardboard cartons and are then preserved solely by storage at −20 C in a deep-freeze refrigerator.[22] With this routine, we have found no change from the original alcohol content of brain tissue after 16 months. Freimuth and co-workers [14b] have demonstrated that storage of tissues in closed glass vessels at ordinary refrigerator temperature (5 C) does not prevent changes from the original alcohol content; the brain alcohol level decreased from 0.22 to 0.12% and the liver alcohol level increased from 0.00 to 0.14% within 14 days.[18]

For preservation of blood specimens, from 0.1 to 1.0% of sodium fluoride (1 to 10 mg. per milliliter) is usually added to prevent glycolysis and other enzymatic changes; this is frequently combined with a supplementary anticoagulant, such as sodium citrate or potassium oxalate, in final concentrations of 0.3 to 0.5%. The following combination of anticoagulant and preservative, used in our laboratories (K. M. D.), preserves the original alcohol content of blood without change for at least 18 days at room temperature, for well over one month when combined with refrigeration at 5 C, and apparently indefinitely when combined with "deep-freeze" storage at –20 C: 150 mg. of sodium fluoride as preservative, plus 1 mg. of heparin sodium as anticoagulant for up to 10 ml. of blood. These salts contained in 4 ml. of stock solution are deposited in film form on the container walls by drying in an oven at 95 to 100 C.[17]

Urine is readily preserved with 15 mg. of sodium fluoride per milliliter of urine, combined with refrigeration; with 3.5 mg. of benzoic acid per milliliter; or with 1 mg. of phenylmercuric nitrate per milliliter.

When specimen aliquots are measured by volume for analysis, the effect of the added substances on the original density of the sample can be neglected for all practical purposes, while such is not the case if the aliquots are to be weighed. Addition of the anticoagulants and preservatives in liquid form is obviously not permissible because of the resulting dilution of the original specimen. Sterile handling and storage of specimens, while desirable, is not necessary if the above directions are followed, particularly when combined with effective refrigeration.

Identity of Sample.—In forensic alcohol determinations, certain routine precautions are necessary to provide legally acceptable proof of specimen identity, integrity (absence of contamination or change from its original condition), and preservation of the chain of custody.[23] Identification of the specimen should be complete and definite, preferably by means of a numbered seal or similar device which simultaneously excludes tampering. Minimal information accompanying a specimen for alcohol determination, in addition to a concise statement of the test desired, should consist of the complete name of the subject from whom it was obtained; the nature of the specimen and site from which it was obtained (when applicable); the place, date, and exact time the specimen was obtained; and the name and other necessary particulars of the person obtaining the specimen.

An occasional problem in forensic analyses is the increasing tendency of courts to require positive affirmative proof of the identity of the subject from whom a disputed specimen was obtained, as well as of the identity of the specimen itself, during subsequent litigation, sometimes years later. We have recently placed the right thumbprint of the subject on the sample-identification record as a precaution against such difficulties. A suggested form for identification of specimens is shown in tables 1 and 2. The form has been in use several years in the laboratory of one of us (K. M. D.).

Analytical Significance of Test Results

Correct interpretation of the analysis in terms of actually existing alcohol concentrations at the sampling time is basic to valid physiological evaluation of alcohol test results. Such analytical interpretation of the results of an alcohol analysis is subject to certain purely technical and scientific considerations unrelated to physiological aspects.

The statutory definitions of alcoholic influence or intoxication promulgated in the United States, and expert testimony concerning the same, uniformly express blood and other body material alcohol concentrations in terms of weight/weight per cent. It is, however, universal practice in the United States to perform practically all clinical chemical analyses upon volumetrically measured specimen aliquots. Such volumetric measurement is desirable for technical reasons, such as the change from original density of a specimen material caused by preservatives, and for the expediency of greater speed with adequate precision. If, however, in interpreting the reported tissue or fluid alcohol levels the deviation from weight/weight percentage is not known or considered, significant misinterpretations can occur. Blood, for example, has an average specific gravity of 1.055 and can have an even greater density if the cell volume is unusually high. Thus a blood alcohol level of 0.152 weight/volume per cent (i. e., 1.52 mg. per milliliter) is equal to a level of only 0.144 weight/weight per cent (i. e., 1.44 mg.

per gram). Reported to two decimal places and without specification these values become, respectively, "0.15%" and "0.14%." A hairline legal interpretation made without awareness of the difference caused by the volumetric sampling could conceivably result in a decision different from that which would have resulted from a report on the weight/weight basis, even though the difference is physiologically negligible. The remedy lies in factual reporting of blood and other alcohol concentrations in terms of the actual measurement employed, accompanied either by an estimated recalculation to any other measurement system of interest or, better, by an explanation of the deviation limits attributable to the difference in measuring technique.

Alcohol determination results should include a statement of the precision limits attached to the measurement. This may be done by reporting a given alcohol level to the first doubtful figure and adding the precision limits (e. g., 0.196±0.004% w/w). Reporting only two significant figures (e. g., 0.19% w/w) is preferable, since it is more meaningful physiologically, and is recommended practice. Few, if any, practical alcohol determination methods have a precision greater than 3 to 5% of the alcohol actually present, and reporting of the third significant figure is entirely unwarranted in the physiologically possible concentration range (0.00 to about 0.70% w/w). In expressing the results quantitatively at all, the analyst implies that the report refers to a single determined substance, universally understood to be ethyl alcohol. The validity of such implication depends on the relative specificity for ethyl alcohol of the particular method employed. It is, consequently, good analytical practice and legally desirable to establish experimentally by qualitative tests, to a reasonable degree of certainty, the presence of ethanol and the absence of any substances which could react like ethanol in the analytical system used.

The concordance between a reported true ethyl alcohol level and the original alcohol level in the sample material at the time the sample was obtained is not under the control of the person making a physiological evaluation of an analysis result. The concentration of ethyl alcohol found in body fluids and tissues is a function of the following factors: (1) concentration of alcohol actually present originally; (2) percentage of recovery of actually present alcohol, a characteristic of the individual analytical method; (3) loss of alcohol originally present, after removal of the specimens from the body, from such causes as enzymatic oxidation, and evaporation; and (4) postremoval gain in alcohol as the result of neoformation, by enzymatic fermentation or other factors. In addition, there is the problem of false apparent alcohol concentrations yielded by nonspecific analytical methods, in the presence of various concentrations of volatile reducing bodies produced by decomposition and putrefaction of biological materials, such as aldehydes, amines, ketones, phenols, and sulfides.

It is apparent that during prolonged intervals between the removal of tissues or fluids for alcohol determination and the analysis, particularly in inadequately preserved specimens, the various factors can operate jointly to reduce or obliterate a low original alcohol level, to reproduce accidentally by loss and neoformation the original concentration, or to produce a significant true or apparent alcohol concentration in an originally alcohol-free specimen. The analyst should make every reasonable effort to preserve the specimen until analyzed in as nearly as possible the original state in which it was received by him; and he should indicate in his report factors which might lead to alteration of any original alcohol concentration, such as evidence of sample decomposition or unusual or unidentified specimen odor.

Appendix A presents the details of four laboratory procedures for analysis of tissue and body liquids for ethyl alcohol.

TABLE 2.—*Reverse of Specimen Identification Form*

DIRECTIONS FOR COLLECTION AND SUBMISSION OF SAMPLE

1. This bottle contains sodium fluoride as a preservative and sodium heparin as an anticoagulant; and is suitable for submission of blood, urine, cerebrospinal fluid or other liquid specimens. Do not add anything other than the sample to the container.
2. Use only a sterile, dry, clean syringe and needle for obtaining specimens and, where necessary, use only a non-alcoholic, non-volatile skin disinfectant. Place approximately 10 ml. of whole blood or other liquid specimen into the bottle, cap tightly, and gently shake about 1 minute to dissolve the chemicals.
3. Replace the specimen bottle and this completed form into container; then seal cap with the wire and numbered seal furnished. If possible, refrigerate entire container until mailed or delivered to the laboratory.
4. The specimen in its sealed container may be delivered to the laboratory by messenger or sent by U. S. Mail, preferably by "CERTIFIED MAIL—RETURN RECEIPT REQUESTED."

On-the-Spot Tests

Characteristics and Application.—The great majority of alcohol determinations on human body materials are performed in connection with the investigation of alleged traffic offenses, chiefly on motor vehicle operators suspected of driving while under the influence of alcohol. While theoretically analysis of any body fluid would suffice for the direct or indirect determination of the blood alcohol concentration at the time of the offense, the indirect determination of the blood alcohol level by breath alcohol analysis has proved to have certain special advantages in these situations.

Inherently, in traffic law enforcement and in a few other special situations (differential diagnosis of intoxication states, particularly in persons in police custody; assessment of fitness for specialized tasks like aircraft piloting, railroading, and industrial operations), it is desirable to obtain immediate information concerning the subject's approximate blood alcohol concentration at the time of the investigation, in order to provide a sound basis for instant corrective or other actions which in many cases have far-reaching effects (e. g., arrest, suspension from employment). Conventional methods for alcohol analysis in body liquids (blood, urine, saliva, etc.) *require relatively elaborate laboratory* facilities frequently not in operation or otherwise unavailable at the time these problems arise, and they usually require longer to perform than it is practical to wait for decisions based on the analysis results. Geographical inaccessibility of such laboratory facilities or even of personnel qualified to obtain blood specimens is a frequent factor in traffic law enforcement, particularly in county and state highway patrol operations.

To provide on-the-spot alcohol analyses of the required reliability and practicability, a number of rapid field procedures have been developed. In practice, because of the requirements for minimal physical facilities and technical proficiency, such on-the-spot techniques are limited to breath alcohol analysis. These breath alcohol analyses all share the following characteristic advantages:

1. A breath alcohol analysis result, usually expressed in terms of the blood alcohol concentration, is obtained within a few minutes.

2. Breath as the analyzed material accurately reflects the actual blood alcohol level at the time of the test, without lag or overrun, and is often obtainable nearer the time in issue than other materials.

3. When breath obtained at the time of the analysis is used as the specimen, the problem of *positively identifying the specimen donor is eliminated*, as are most of the collection, identification, preservation, transportation, and evidentiary safeguard problems common to other body materials, together with the need for specially qualified collection personnel, for special collection facilities and containers, and for most of the precautions outlined in detail in the section entitled "Sampling for Laboratory Tests."

4. Since breath analysis eliminates certain difficult steps of the tissue and liquid alcohol analyses, requirements for technical background and skill of the analyst are greatly reduced.

5. Required test facilities can be minimal and are usually limited to the self-contained breath alcohol apparatus used, costs per test after acquisition of the necessary equipment being generally much lower than for comparable laboratory analysis.

6. There is frequently less objection by the tested subject to collection of a breath sample for alcohol analysis than to the body penetration required to obtain a blood specimen, and generally less cooperation and considerably less time are required than for collection of adequate saliva or urine specimens. The embarrassment connected with obtaining a urine specimen under observation is avoided.

7. Multiple, replicate, and serial alcohol determinations at frequent brief intervals are practical, because of the rapidity and relative simplicity of on-the-spot analyses and the rapid nontraumatic sampling of breath specimens, allowing accurate determination of the directional trend of the blood alcohol curve and *many experimental analyses* on a given subject.

On-the-spot breath analyses also embody a few inherent limitations:

1. Entire breath specimens cannot be effectively preserved for later replicate or independent confirmatory analysis, although the alcohol from a measured volume of breath can be collected and preserved for later analysis.

2. Some cooperation is required from the patient for collection of an adequate breath specimen, the extent varying with the nature of the required breath sample (alveolar air, mixed expired air, or rebreathed air) and the collection apparatus (balloon, sample chamber of apparatus, etc.).

3. Most breath alcohol methods, except, under some conditions, those employing the alcohol–carbon dioxide ratio, are inapplicable to unconscious or completely uncooperative subjects.

4. A period of approximately 10 to 15 minutes after the last ingestion of alcohol (or regurgitation) must elapse before breath alcohol analysis, to insure elimination of the possible effects of any residual mouth alcohol.

These characteristics of the on-the-spot alcohol tests make them highly useful as rapid and simple screening tests to indicate or obviate the need for confirmatory body fluid alcohol determination, such as *blood alcohol determination, and to furnish* approximate blood alcohol level data. Under properly controlled conditions, which include proper training and continuing expert supervision of competent operators and adequate expert control of equipment, reagents, and procedures, the on-the-spot tests are also capable of yielding accurate breath alcohol concentration results, acceptable as an index of blood alcohol concentration of adequate reliability for clinical and legal purposes.[25] The significant human physiological characteristics (blood composition, body temperature, respiratory action, etc.) normally vary within sufficiently narrow limits to permit full realization of this technical potential.[26]

General Principles.—Since the first application of breath alcohol analysis to medical purposes in the United States by Bogen in 1927, a number of breath alcohol analysis methods and devices have been developed. They fall into three functional categories: (1) laboratory alcohol determinations, performed on laboratory-collected breath specimens, or on those collected in the field with on-the-spot breath screening-and-collecting equipment, yielding definitive blood alcohol level results; (2) field (on-the-spot) breath alcohol determinations employing portable apparatus and yielding definitive blood alcohol level results; and (3) semiquantitative field (on-the-spot) breath alcohol screening tests employing portable apparatus or disposable single-test units, yielding only approximate blood alcohol level results.

All breath alcohol analyses depend on the fundamental principle that the distribution of alcohol between circulating pulmonary blood and alveolar air occurs by simple diffusion and, like that of other volatile substances, obeys Henry's law, meaning that distribution equilibrium exists and that consequently for a given temperature a constant ratio exists between the concentrations of alcohol in the blood and in alveolar air. (Henry's law is as follows: The mass of gas dissolved by a given volume of solvent, at constant temperature, is proportional to the pressure of the gas with which it is in equilibrium, whence concentration of gas in liquid phase ÷ concentration of gas in gaseous phase = constant at a definite temperature.)

There is general agreement that the mean value of this Ostwald partition ratio of blood alcohol concentration to alveolar air alcohol concentration at the average temperature of exhaled air (34 C) is approximately 2,100:1; i. e., 2,100 ml. of alveolar air contain the same quantity of alcohol as 1 ml. of blood.[27] The breath alcohol methods determine the quantity of alcohol in a known volume of breath or measure the breath volume required to furnish a known quantity of alcohol, in either case yielding a breath alcohol concentration, generally expressed in milligrams of alcohol per liter of breath. From the blood alcohol–alveolar air alcohol ratio of 2,100:1 and knowledge of the alveolar air content of the analyzed breath sample, the corresponding blood alcohol level is then readily calculated. Alcohol quantitation is accomplished by the same general chemical principles outlined under "Basic Principles of Chemical Tests," above, usually controlled oxidation with iodine pentoxide, potassium dichromate in acid solution, or potassium permanganate in acid solution.

A key element in each breath alcohol method is the procedure employed for determination of the quantity of alveolar air actually analyzed for its alcohol content, the following methods being employed:

1. Alveolar air is collected, as by mechanically trapping the final portion of a prolonged expiration (volume greater than 400 ml.), and analyzed directly.

2. Rebreathed ("venous") air, which is identical in alcohol concentration to alveolar air, is obtained by having the subject rebreathe ordinary expired air four or five times with the nostrils closed and is analyzed directly.

3. Mixed expired air is collected and analyzed for alcohol and carbon dioxide content. The proportion of alveolar air in the sample is estimated from its carbon dioxide concentration on the basis of observations that the alveolar air of normal individuals contains about 5.5% carbon dioxide by volume, while atmospheric air contains only approximately 0.03 vol. % carbon dioxide.

4. Mixed expired air is collected and analyzed for alcohol only. As screening methods for the estimation of the approximate blood alcohol level, some "volumetric" tests assume that ordinary expired breath normally contains about 58 to 63% alveolar air and hence employ an equivalence factor of approximately 3,200 ml. of ordinary mixed expired breath measured at 25 C as containing the same quantity of alcohol as 1 ml. of blood.

Reliability.—Correlation Between Blood Alcohol Levels Obtained by Direct Blood Analysis and from Breath Analysis: The validity of breath alcohol analysis for the determination of the blood alcohol level depends on two components: the analytical reliability of the breath alcohol analysis itself and the constancy to the required extent of the human physiological variables affecting the formulas for conversion of the breath alcohol concentration to blood alcohol concentration. Both factors are tested by examining the closeness with which breath alcohol analyses predict actual blood alcohol levels. Consequently, the correlation between breath analysis–derived blood alcohol levels and those obtained by direct blood analysis has been universally employed as a measure of the reliability of breath alcohol analyses for the indirect determination of blood alcohol concentrations and has been extensively studied.

In evaluating such studies, the physiological and technical variables inherent in blood alcohol analysis as well as those attending breath alcohol analysis must be recognized and considered. Analytically, the blood alcohol methods are subject to considerable variation in reliability, with the chemical accuracy, precision, and specificity of some methods for the determination of blood alcohol being far inferior to those of reliable methods for the determination of breath alcohol. Consequently, the significant reliability characteristics of the referee blood alcohol method must be known and considered in comparing the results of simultaneous blood and breath alcohol analyses. Any substantial difference in collection times of blood and breath specimens should also

experimental studies of the
yed breath alcohol methods
cently, employing adequate-
reliable referee blood and urine alcohol methods and models of the Alcometer, Breathalyzer, Drunkometer, and Intoximeter in current production at the time of the respective tests. These recent studies uniformly and conclusively demonstrate that breath alcohol analysis performed by competent operators under expert supervision with properly controlled apparatus, reagents, and procedures can justifiably

for alcohol analysis in body liquids (blood, urine, saliva, etc.) require relatively elaborate laboratory facilities frequently not in operation or otherwise unavailable at the time these problems arise, and they usually require longer to perform than it is practical to wait for decisions based on the analysis results. Geographical inaccessibility of such laboratory facilities or even of personnel qualified to obtain blood specimens is a frequent factor in traffic law enforcement, particularly in county and state highway patrol operations.

To provide on-the-spot alcohol analyses of the required reliability and practicability, a number of rapid field procedures have been developed. In practice, because of the requirements for minimal physical facilities and technical proficiency, such on-the-spot techniques are limited to breath alcohol analysis. These breath alcohol analyses all share the following characteristic advantages:

1. A breath alcohol analysis result, usually expressed in terms of the blood alcohol concentration, is obtained within a few minutes.
2. Breath as the analyzed material accurately reflects the actual blood alcohol level at the time of the test, without lag or overrun, and is often obtainable nearer the time in issue than other materials.
3. When breath obtained at the time of the analysis is used as the specimen, the problem of positively identifying the specimen donor is eliminated, as are most of the collection, identification, preservation, transportation, and evidentiary safeguard problems common to other body materials, together with the need for specially qualified collection personnel, for special collection facilities and containers, and for most of the precautions outlined in detail in the section entitled "Sampling for Laboratory Tests."
4. Since breath analysis eliminates certain difficult steps of the tissue and liquid alcohol analyses, requirements for technical background and skill of the analyst are greatly reduced.
5. Required test facilities can be minimal and are usually limited to the self-contained breath alcohol apparatus used, costs per test after acquisition of the necessary equipment being generally much lower than for comparable laboratory analysis.
6. There is frequently less objection by the tested subject to collection of a breath sample for alcohol analysis than to the body penetration required to obtain a blood specimen, and generally less cooperation and considerably less time are required than for collection of adequate saliva or urine specimens. The embarrassment connected with obtaining a urine specimen under observation is avoided.
7. Multiple, replicate, and serial alcohol determinations at frequent brief intervals are practical, because of the rapidity and relative simplicity of on-the-spot analyses and the rapid nontraumatic sampling of breath specimens, allowing accurate determination of the directional trend of the blood alcohol curve and many experimental analyses on a given subject.

On-the-spot breath analyses also embody a few inherent limitations:

1. Entire breath specimens cannot be effectively preserved for later replicate or independent confirmatory analysis, although the alcohol from a measured volume of breath can be collected and preserved for later analysis.
2. Some cooperation is required from the patient for collection of an adequate breath specimen, the extent varying with the nature of the required breath sample (alveolar air, mixed expired air, or rebreathed air) and the collection apparatus (balloon, sample chamber of apparatus, etc.).
3. Most breath alcohol methods, except, under some conditions, those employing the alcohol–carbon dioxide ratio, are inapplicable to unconscious or completely uncooperative subjects.
4. A period of approximately 10 to 15 minutes after the last ingestion of alcohol (or regurgitation) must elapse before breath alcohol analysis, to insure elimination of the possible effects of any residual mouth alcohol.

These characteristics of the on-the-spot alcohol tests make them highly useful as rapid and simple screening tests to indicate or obviate the need for confirmatory body fluid alcohol determination, such as blood alcohol determination, and to furnish approximate blood alcohol level data. Under prop

yielding definitive blood alcohol level resul
field (on-the-spot) breath alcohol determina
employing portable apparatus and yielding definitive blood alcohol level results; and (3) semiquantitative field (on-the-spot) breath alcohol screening tests employing portable apparatus or disposable single-test units, yielding only approximate blood alcohol level results.

All breath alcohol analyses depend on the fundamental principle that the distribution of alcohol between circulating pulmonary blood and alveolar air occurs by simple diffusion and, like that of other volatile substances, obeys Henry's law, meaning that distribution equilibrium exists and that consequently for a given temperature a constant ratio exists between the concentrations of alcohol in the blood and in alveolar air. (Henry's law is as follows: The mass of gas dissolved by a given volume of solvent, at constant temperature, is proportional to the pressure of the gas with which it is in equilibrium, whence concentration of gas in liquid phase ÷ concentration of gas in gaseous phase = constant at a definite temperature.)

There is general agreement that the mean value of this Ostwald partition ratio of blood alcohol concentration to alveolar air alcohol concentration at the average temperature of exhaled air (34 C) is approximately 2,100:1; i. e., 2,100 ml. of alveolar air contain the same quantity of alcohol as 1 ml. of blood.[27] The breath alcohol methods determine the quantity of alcohol in a known volume of breath or measure the breath volume required to furnish a known quantity of alcohol, in either case yielding a breath alcohol concentration, generally expressed in milligrams of alcohol per liter of breath. From the blood alcohol–alveolar air alcohol ratio of 2,100:1 and knowledge of the alveolar air content of the analyzed breath sample, the corresponding blood alcohol level is then readily calculated. Alcohol quantitation is accomplished by the same general chemical principles outlined under "Basic Principles of Chemical Tests," above, usually controlled oxidation with iodine pentoxide, potassium dichromate in acid solution, or potassium permanganate in acid solution.

A key element in each breath alcohol method is the procedure employed for determination of the quantity of alveolar air actually analyzed for its alcohol content, the following methods being employed:

1. Alveolar air is collected, as by mechanically trapping the final portion of a prolonged expiration (volume greater than 400 ml.), and analyzed directly.

2. Rebreathed ("venous") air, which is identical in alcohol concentration to alveolar air, is obtained by having the subject rebreathe ordinary expired air four or five times with the nostrils closed and is analyzed directly.

3. Mixed expired air is collected and analyzed for alcohol and carbon dioxide content. The proportion of alveolar air in the sample is estimated from its carbon dioxide concentration on the basis of observations that the alveolar air of normal individuals contains about 5.5% carbon dioxide by volume, while atmospheric air contains only approximately 0.03 vol. % carbon dioxide.

4. Mixed expired air is collected and analyzed for alcohol only. As screening methods for the estimation of the approximate blood alcohol level, some "volumetric" tests assume that ordinary expired breath normally contains about 58 to 63% alveolar air and hence employ an equivalence factor of approximately 3,200 ml. of ordinary mixed expired breath measured at 25 C as containing the same quantity of alcohol as 1 ml. of blood.

Reliability.—Correlation Between Blood Alcohol Levels Obtained by Direct Blood Analysis and from Breath Analysis: The validity of breath alcohol analysis for the determination of the blood alcohol level depends on two components: the analytical reliability of the breath alcohol analysis itself and the constancy to the required extent of the human physiological variables affecting the formulas for conversion of the breath alcohol concentration to blood alcohol concentration. Both factors are tested by examining the closeness with which breath alcohol analyses predict actual blood alcohol levels. Consequently, the correlation between breath analysis–derived blood alcohol levels and those obtained by direct blood analysis has been universally employed as a measure of the reliability of breath alcohol analyses for the indirect determination of blood alcohol concentrations and has been extensively studied.

In evaluating such studies, the physiological and technical variables inherent in blood alcohol analysis as well as those attending breath alcohol analysis must be recognized and considered. Analytically, the blood alcohol methods are subject to considerable variation in reliability, with the chemical accuracy, precision, and specificity of some methods for the determination of blood alcohol being far inferior to those of reliable methods for the determination of breath alcohol. Consequently, the significant reliability characteristics of the referee blood alcohol method must be known and considered in comparing the results of simultaneous blood and breath alcohol analyses. Any substantial difference in collection times of the blood and breath specimens should also be considered, particularly in the light of the usual experimental conditions which sometimes preclude complete alcohol distribution equilibrium. These external variables, of course, are absent in correlation studies of the results of simultaneous breath alcohol analyses by different systems or instruments.

Carefully controlled experimental studies of the more commonly employed breath alcohol methods have been conducted recently, employing adequately reliable referee blood and urine alcohol methods and models of the Alcometer, Breathalyzer, Drunkometer, and Intoximeter in current production at the time of the respective tests. These recent studies uniformly and conclusively demonstrate that breath alcohol analysis p [illegible] ly competent operators under expert sup [illegible] h properly controlled apparatus, rea [illegible] dures can justifiably be expected consistently to yield by calculation blood alcohol concentration results within 0.015 weight per cent ethanol of those obtained by direct analysis of blood. The same deviation limits can usually be expected between calculated blood alcohol levels from simultaneous breath analyses by two or more different breath alcohol methods.

Specificity: The specificity of on-the-spot breath alcohol analysis methods is an important consideration, since the nature of most of these tests precludes analytically establishing the absence of interferents; that is, volatile reducing substances which like ethyl alcohol diffuse from the blood into the alveolar air and some of which can reduce the commonly employed oxidizing reagents.

The major reagents employed for alcohol quantitation in breath are iodine pentoxide, potassium dichromate in sulfuric acid solution, and potassium permanganate in sulfuric acid. Of these, iodine pentoxide is the least selective reagent for ethanol, since it readily oxidizes many organic substances, including aldehydes, carbon monoxide, ethyl ether, various hydrocarbons, ketones, and methyl alcohol. Potassium dichromate in acid solution is known to react with aldehydes, ether, methyl alcohol, etc. In general, low concentrations of acetone cause no interference under the reaction conditions employed in breath tests, and food-derived odoriferous flavor substances cause none. Potassium permanganate in approximately 15 *N* sulfuric acid at room temperature, as used in breath alcohol analysis, is probably the test reagent most selective for ethanol, being unaffected by acetone and many volatile food-derived substances in the low concentrations found in breath (citrus fruit oils, cheeses, garlic, onions, etc.), although it reacts with acetaldehyde. Only iodine pentoxide is significantly affected by tobacco smoke, which in practical breath test operation, of course, is totally excluded.

TABLE 3.—*Comparison of Current Major on-the-Spot Breath Alcohol Test Methods*

Apparatus Employed	Method: Developer(s)	Method: Yr. Published	Material Analyzed	Alcohol Equivalent of 1 Ml. of Blood	Reagent Used for Alcohol Quantitation	Test Category	Approximate Cost of Apparatus
Alcometer	*Greenberg and Keator*	*1941*	*Alveolar breath, 12 ml.*	*2,100 ml.*	*Iodine pentoxide*	Quantitative breath analysis	$700 +0.38/test
Alcotest	Grosskopf and Scheibe	1953	Mixed expired breath, 1,000 ml.	3,300 ml. at 34 C	Potassium dichromate in sulfuric acid	Preliminary screening test	$0.75/test
Breathalyzer	Borkenstein	1954	Alveolar breath, 52.5 ml.	2,100 ml.	Potassium dichromate in sulfuric acid	Quantitative breath analysis	$595 +0.60/test
Drunkometer	Harger and co-workers	1938	Mixed expired breath, volume varies	Alcohol-CO_2 ratio: 190 mg. CO_2	Potassium permanganate in sulfuric acid	Quantitative breath analysis	$225 +0.60/test
		1938	Mixed expired breath, volume varies	3,200 ml., CO_2-free, at 25 C	Potassium permanganate in sulfuric acid	Preliminary screening test	Included with above
		1956	Rebreathed air, volume varies	2,100 ml.	Potassium permanganate in sulfuric acid	Quantitative breath analysis	$225 +0.60/test
Drunkotester	Kitagawa and Kobayashi	1953	Mixed expired breath, 100 ml.	3,300 ml. at 25 C	Potassium dichromate in sulfuric acid	Preliminary screening test	$21.50 +0.20/test
Intoximeter	Forrester and co-workers	1941	Mixed expired breath, volume varies	Alcohol-CO_2 ratio: 190 mg. CO_2	Laboratory analysis	Breath collection unit for laboratory quantitative analysis	$4.25 for collecting unit
		1941	Mixed expired breath, volume varies	2,800 ml. at 34 C	Potassium permanganate in sulfuric acid	Preliminary screening test	Included with above

The general alcohol specificity and characteristics of the several reagents are further modified by other variables of the individual breath alcohol methods, such as breath volume analyzed and reaction temperature. Consequently, each breath alcohol method must be evaluated as a whole in regard to its freedom from chemical interference. The entire interference problem is somewhat academic, because in the conditions under which breath tests are employed, predominantly in traffic law enforcement, substances chemically capable of interfering are generally not present in concentrations yielding markedly false apparent alcohol levels. Conversely, the possible presence of food odors, halitosis, and similar conditions will not prevent complete reaction of alcohol with the breath test reagents, nor will masking of beverage odors on the breath, as by chlorophyllin, affect the alcohol content of the breath or the breath alcohol tests.

True reactions with alcohol in expired breath from sources other than the alveolar air (eructation, regurgitation, vomiting) will, of course, vitiate the breath alcohol results but can be detected by observation of the test subject and prevented by the subject's rinsing out his mouth with water.

The rapidity and simplicity of the breath alcohol tests and the individual differences in sensitivity to nonalcohol reducing substances actually lend themselves to a unique application as a semiautomatic qualitative chemical identification system differentiating ethyl alcohol from other reducing substances: Substantially identical alcohol level results (two or more results agreeing within 0.015% w/w) obtained by two different chemical reaction principles (e. g., iodine pentoxide and potassium permanganate oxidations) offer chemical proof of the reducing substance measured being ethyl alcohol, as well as reasonably conclusive evidence of the proper functioning of each test. Presence of a significant concentration of nonalcoholic reducing substance in the breath (with or without presence of ethanol) would affect the different chemical trains in a nonidentical manner and to different degrees and would, therefore, yield quantitatively different apparent "ethyl alcohol" results. For example, presence of much acetone in the breath would cause substantial apparent "alcohol" level results in instruments employing the iodine pentoxide reaction but would not affect breath alcohol methods utilizing potassium permanganate in acid solution.

Calibration and Testing of Apparatus.—The several commercial breath alcohol apparatus either incorporate instrument scales reading directly in blood alcohol concentration or provide calibration tables yielding blood alcohol levels from the observed variables (breath volume analyzed, weight of carbon dioxide absorbed, etc.). The accuracy of blood alcohol concentration predictions by these means can, of course, be checked by direct analysis of a simultaneously obtained blood sample, keeping in mind the referee method limitations.

Simpler methods and apparatus have, however, been developed for calibration and testing of breath alcohol determination instruments, employing mixtures of ethyl alcohol in air or other gases. Careful experimental work has established considerable independently confirmed data on the partition ratio of alcohol between air and water at various temperatures. Using this information, one can easily prepare various known concentrations of alcohol in air by equilibrating air with aqueous alcohol solutions of known concentration. A simple equilibrator consists essentially of a closed metal, glass, or plastic cylinder bearing an air inlet tube terminating in a porous gas-dispersion disk or cylinder, a thermometer, and an air outlet tube connected to a liquid trap. Room air is forced through a 5-cm. layer of alcohol solution by means of an atomizer bulb, in a flow of very small air bubbles, thus attaining complete alcohol distribution equilibrium in one passage; the resulting alcohol concentration of the effluent air is controlled by the concentration of alcohol in the solution and by the temperature.

Analysis of an adequate number of such known air-alcohol mixtures in a breath alcohol apparatus will yield the necessary information for preparation of calibration scales or calibration tables. The original and continuing validity of these or of factory precalibrations can be readily confirmed whenever desired by analysis of one or more air alcohol samples.

EXAMPLE OF CALIBRATION CHECK:

1. The mean alcohol partition ratio constant for the air-water system, $k_{A/W}$, is 0.000217 at 25.0 C. (Ostwald partition ratio coefficient, $k_{A/W}$=weight of alcohol per unit volume of air÷weight of alcohol per unit volume of water.) Hence, 1 liter of air equilibrated at 25 C with water containing 4 mg. of ethanol per milliliter will contain $(1{,}000 \times 4 \times 0.000217) = 0.868$ mg. of alcohol.

2. 2,100 ml. of this air, warmed to 34 C, will contain

$$[2.1 \times \frac{(273+25)^\circ}{(273+34)^\circ} \times 0.868 =]\ 1.769 \text{ mg. of alcohol.}$$

3. A person whose alveolar air contains the same alcohol concentration, 1.769 mg./2,100 ml., will have a blood alcohol level of (1.76 mg./ml.)=0.17% w/v, according to the established blood-alveolar air partition ratio of 2,100:1 at 34 C.

4. Analysis of the above air-alcohol mixture in a breath alcohol apparatus should, therefore, yield the theoretical blood alcohol concentration reading of 0.17% w/v, or (0.17/1.055)=0.16% w/w.

Breath Alcohol Tests

Methods for breath alcohol analysis have been used for many years. The principles and techniques of practical breath alcohol testing as an on-the-spot method will be illustrated by describing briefly in appendix B the components and operation of the six presently commercially available breath alcohol instruments: the Alcometer, the Alcotest, the Breathalyzer, the Drunkometer, the Drunkotester, and the Intoximeter. Some characteristics of each apparatus and of the methods developed for its use are shown in table 3.

Appendix A

LABORATORY PROCEDURES FOR ANALYSIS OF TISSUES AND BODY LIQUIDS FOR ETHYL ALCOHOL

Four methods for the determination of ethyl alcohol in biological materials, all presently well known and widely used in the United States, will be described as exemplifying the many published procedures. Their selection for discussion here does not imply any inferiority of any other procedure. The methods described are equally applicable to tissues, blood, urine, and other body fluids, with some slight modifications for each type of body material. For example, tissues require initial preparation by grinding, blending, or fine comminution to assure homogeneity. Tissue homogenates and blood may be treated by preliminary precipitation of proteins, or they may be distilled directly with the addition of protein precipitants to the distillation flask. The methods described have several common characteristics: all employ distillation for separation of the ethyl alcohol from the specimen; the alcohol in the distillate is quantitated in each by oxidation, using potassium dichromate in sulfuric acid solution below the critical concentration of 20 *N*, the oxidations, in fact, being carried out at less than 18 *N* acidity. Under these conditions, ethyl alcohol in the distillate is quantitatively oxidized to acetic acid and volatile impurities exert minimal interference.

The differences between the methods are in (*a*) the method of distillation, whether by direct distillation or distillation of a deproteinized filtrate; (*b*) the choice of protein precipitants; (*c*) the size, type, and construction of the distillation apparatus; (*d*) the sulfuric acid concentration (ranging from about 17 *N* to 2 *N*) and the potassium dichromate concentration used during the oxidation, with consequent differences in the range of alcohol concentration of the several methods; and (*e*) the measurement of changes in the oxidizing reagent, whether by visual colorimetry, spectrophotometry, or titrimetry. The last represents the most important and distinctive difference between these methods.

Heise Method

The Heise method[7] is as follows:

Principle.—The specimen, commonly blood or urine, is distilled directly from a mixture of picric and tartaric acids to precipitate the proteins and reduce foaming. Varying volumes of distillate in a series of test tubes are made to a constant volume with distilled water. A measured volume of potassium dichromate in sulfuric acid is added and the resulting mixture, at 7 to 8 *N* acidity, is heated in a boiling water bath. The resulting colors are compared visually against a series of 21 color standards prepared with known quantities of ethyl alcohol.

TABLE 4.—*Strong Permanent Standards*

Nominal % Alcohol	Alcohol by Weight	Water, Ml.
0.00	0.00 ml.	1.00
0.00	0.50 ml. of 0.10% by weight	0.50
0.10	1.00 ml. of 0.10% by weight	0.00
0.12	0.60 ml. of 0.20% by weight	0.40
0.14	0.70 ml. of 0.20% by weight	0.30
0.16	0.80 ml. of 0.20% by weight	0.20
0.18	0.90 ml. of 0.20% by weight	0.10
0.20	1.00 ml. of 0.20% by weight	0.00
0.22	0.73 ml. of 0.30% by weight	0.27

Apparatus

1. Distilling apparatus: 500-ml. distilling flask and small condenser. (Equipment and reagents for this procedure are available from LaMotte Chemical Products Co., Towson, Baltimore 4, Md.)
2. Pipets, volumetric.
3. Water bath.

Reagents.—All reagents for this and all following procedures are prepared with analytical reagent grade, chemically pure (C. P.) reagents and distilled water free of reducing substances as shown by suitable purity tests.

1. Oxidizing reagent: 0.33% potassium dichromate in 50% sulfuric acid by volume.
2. Protein precipitants: half-saturated picric acid solution, containing 10% tartaric acid.

Procedure A: Urine Analysis

1. Slowly distill a mixture of 10 ml. of urine and about 10 ml. of picric-tartaric acid protein precipitant from a 500-ml. Florence flask, collecting the first 10 ml. of distillate.
2. Into separate test tubes similar to those used for the standards, place 1 ml. and progressively smaller measured volumes of distillate, making the volume up to 1 ml. in each case with distilled water. Add 3 ml. of the oxidizing reagent to each tube; mix, stopper, and place the tubes in a boiling water bath for four minutes.
3. Cool test tubes and visually compare the resulting colors by transmitted light against the "strong permanent standards" prepared as described in table 4. Divide the nominal alcohol concentration of the matching standard tube by the fraction of 1 ml. of distillate oxidized, to obtain the alcohol percentage of the original urine specimen.
4. If the results are too low to be read, use the weak standards and follow steps 2 and 3 of procedure B below, in which event the alcohol percentage of the original urine specimen=[nominal alcohol concentration of standard ÷ volume of distillate used (milliliters)]×2.

Procedure B: Blood Analysis

1. Add 2 ml. of whole blood to about 15 ml. of the picric-tartaric acid protein precipitant. Distill slowly and collect the first 10 ml. of distillate.
2. Into separate test tubes similar to those used for the standards, place 2 ml. and smaller measured volumes of distillate, making the volume up to 2 ml. in each case with distilled water. Add 1 ml. of the oxidizing reagent to each tube; mix, stopper, and place in a boiling water bath for 12 minutes.
3. Cool the test tubes and visually compare the colors against those of the "weak permanent standards" prepared as described in table 5. Multiply the nominal alcohol concentration of the matching standard tube by [10 ÷ volume of distillate used (milliliters)] to obtain the alcohol percentage of the original blood specimen.

Preparation of Standards

1. Strong Permanent Standards: To each of nine test tubes of uniform diameter add the volumes of alcohol solution and of distilled water indicated in table 4. Add to each tube 3 ml. of oxidizing reagent; stopper the tubes, place in boiling water for four minutes, cool, and seal.
2. Weak Permanent Standards: To each of 12 test tubes of uniform diameter add the volumes of alcohol solution and of distilled water indicated in table 5. Add to each tube 1 ml. of oxidizing reagent; stopper the tubes, place in a boiling bath for 12 minutes, cool, and seal.

Critique.—This is the simplest of the four procedures described, requiring relatively little laboratory space and no special glassware or apparatus. The alcohol recovery of the method as originally described by the author is not as accurate or constant as in the other three methods which follow, chiefly because of the large capacity of the apparatus compared to the small volume of liquid. The distillation is tedious, and much foaming may be encountered with blood samples. The color standard provide steps in color changes (not a continuous series) to which the unknown is approximated. The method thus incorporates both systematic errors and a small, variable, subjective error. Recoveries of 91 to 112% of added alcohol by this method have been reported. A single analysis requires about 20 minutes. Acetone, chloroform, and ether do not interfere in this method.

However, the accuracy and speed of the procedure approaches that of the other methods which will be described, provided the all-glass distillation apparatus and the antifoam agents or precipitants of those methods are used.

Dubowski Method

The Dubowski method [4] is as follows:

Principle.—Specimens of any body fluid (or steam distillates of tissue homogenates) are distilled directly from tungstic acid to precipitate the proteins. An aliquot of the distillate is mixed with a measured volume of standard potassium dichromate in sulfuric acid and the resulting mixture, at 15 *N* acidity, is oxidized at 100 C. The residual potassium dichromate is measured spectrophotometrically at 450-mμ wave length and the corresponding alcohol concentration of the original specimen is obtained from a calibration curve or table prepared from analysis of solutions of known alcohol content.

Apparatus

1. Distilling apparatus: Direct and steam distillation apparatus of Dubowski and Shupe [27] (catalog number SB-1715X, Scientific Glass Apparatus Co., Inc., Bloomfield, N. J.) or distillation apparatus of Harger (see below).
2. Fluid bath: Electric water bath at 100 C or electric constant temperature bath at 100 C, with permanent water-soluble bath fluid (UCON fluid 50-HB-280X, Carbide & Carbon Chemicals Co., 30 E. 42nd St., New York 17, N. Y.).
3. Photometer: Beckman model DU or model B spectrophotometers; Bausch and Lomb Spectronic-20 spectrophotometer; Coleman model 14, 6B, 6C, or 6D spectrophotometers; or filter photometer with microcuvettes and blue filter transmitting in the region of about 450 mμ.
4. Volumetric ware: good grade of pipets and glass-stoppered volumetric flasks.

Reagents

1. Oxidizing reagent: 0.0214 *N* potassium dichromate; 1.0500 Gm. $K_2Cr_2O_7$ in 1 liter of 50 vol. % sulfuric acid. One milliliter of this reagent is equivalent to 0.247 mg. of ethyl alcohol.
2. Sodium tungstate, 10% w/v.
3. Sulfuric acid, 2/3 *N*.
4. Tartaric acid, 10% w/v.

Procedure A for Blood, Urine, Saliva, Cerebrospinal Fluid, Tissue Distillates

1. Place specimen and reagents, as follows, into a 125-ml. distilling flask (a 250-ml. flask in the case of blood): 10 ml. of distilled water (20 ml. for blood analysis only); 2 ml. of the specimen (1-ml. specimens can be analyzed by collecting the distillate in a 5-ml. volumetric flask, proceeding with steps 3 through 5 as usual); 5 ml. of 2/3 *N* sulfuric acid; and 5 ml. of 10% sodium tungstate. Mix the contents by rotation and attach the flask to the distillation apparatus. Begin distillation when the blood has coagulated completely and has changed to a dark brown color.
2. Distill slightly less than 10 ml. directly into a 10-ml. glass-stoppered volumetric flask in about 8 to 10 minutes, using a microburner with a shielded 2.5-to-4-cm. flame. Make the distillate to the 10 ml. mark with distilled water, stopper, and mix thoroughly.
3. Into a 16-by-125-ml. borosilicate glass culture tube with Teflon-lined screw cap, place, in order, 1 ml. of distillate and 5 ml. of oxidizing reagent and mix by vigorous rotation. Immediately close the tube with the screw cap and heat for eight minutes in the 100 C fluid bath, immersing the tube above the liquid level.
4. Cool the tube to room temperature (25 C or less) under running tap water or in an ice bath; mix the contents by rotation, and transfer a portion of the solution into a cuvette. Determine the photometric reading (optical density or per cent of transmittancy) at 450 mμ wave length, after setting the instrument at 100% transmittancy with a reference cuvette containing distilled water.
5. Obtain the alcohol concentration of the unknown specimen, in per cent weight/volume, from a calibration table or curve prepared by subjecting a series of biological specimens of known alcohol content to the entire analysis.

Table 5.—*Weak Permanent Standards*

Nominal % Alcohol	Alcohol by Weight	Water, Ml.
0.000	0.00 ml.	2.00
0.005	1.00 ml of 0.01% by weight	1.00
0.010	2.00 ml. of 0.01% by weight	0.00
0.013	0.52 ml. of 0.05% by weight	1.48
0.016	0.64 ml. of 0.05% by weight	1.36
0.019	0.76 ml. of 0.05% by weight	1.24
0.022	0.88 ml. of 0.05% by weight	1.12
0.025	1.00 ml. of 0.05% by weight	1.00
0.028	1.12 ml. of 0.05% by weight	0.88
0.031	1.24 ml. of 0.05% by weight	0.76
0.034	1.36 ml. of 0.05% by weight	0.64
0.037	1.48 ml. of 0.05% by weight	0.52

Procedure B for Tissues

1. Rapidly liquefy about 10 Gm. of frozen, or ice-cold, tissue in an ice-cold Waring blendor. Weigh out rapidly 2 Gm. of the liquefied sample to the nearest 0.01 Gm. and transfer quantitatively to a

250-ml. distilling flask with 30 ml. of 10% tartaric acid solution. Add 2 to 3 drops of antifoam fluid or use silicone antifoam compound (Dow Corning antifoam AF emulsion 30%, used as a 10% emulsion; Dow Corning antifoam A spray: Dow Corning Corp., Midland, Mich.; antifoam 60 emulsion, General Electric Co., Silicone Products Department, Waterford, N. Y.) or 0.1 Gm. of low-melting paraffin compound. Mix by rotation and attach flask to the steam distillation apparatus.

2. Distill in a rapid current of steam from a generator containing distilled water. Collect about 20 to 30 ml. of distillate in a 125-ml. distilling flask within 8 to 10 minutes.

3. To the 125-ml. distilling flask containing the above steam distillate add, in order, 5 ml. of ⅔ *N* sulfuric acid and 5 ml. of 10% sodium tungstate. Mix by rotation, attach to the distillation apparatus, and proceed as for biological liquids (steps 2-4 of procedure A).

4. Obtain the alcohol concentration of the tissue, expressed in percentage by weight, as in step 5, procedure A, from the same calibration table.

Special Procedures, C

1. Partially decomposed specimens are first distilled from the acid tungstate solution into another 125-ml. distilling flask, to which are then added 10 ml. of saturated aqueous mercuric chloride and 10 ml. of 10% calcium hydroxide suspension. This mixture is then redistilled and the analysis is completed as in procedure A.

2. Submicro and ultramicro determinations are carried out on fresh blood and urine specimens in Conway-type porcelain diffusion cells (catalog numbers 4472-F and 4472-H, Arthur H. Thomas Co., Philadelphia 5, Pa.). For submicroanalysis, 0.10 ml. of whole blood or urine is placed in the outer ring chamber of a 68-mm. diameter Conway unit, together with 1.00 ml. of saturated potassium carbonate to facilitate release of alcohol; 2.50 ml. of potassium dichromate oxidizing reagent is placed in the center well.

For ultramicroanalysis, 0.020 ml. of sample is placed in the outer ring chamber of a 44-mm. diameter Conway unit, together with 0.50 ml. of saturated potassium carbonate; 0.50 ml. of the above potassium dichromate oxidizing reagent is placed in the center well. The cell covers, lubricated with silicone stopcock grease, are applied, and the units are allowed to stand at room temperature of 12 hours, or at 38 C for 2 hours. The contents of the center well are then quantitatively transferred to microvolumetric flasks and made up with distilled water to 5 ml. or 2 ml. in the respective submicro or ultramicro methods. Photometry is carried out in the Beckman model DU spectrophotometer at 450 mμ, using silica microcuvettes whose light path is 10 mm. The alcohol concentration of the original specimen is obtained directly from calibration tables prepared by carrying a series of blood samples of known alcoholic content through complete analyses by the respective methods.

Critique.—The procedure resembles the Heise method; however, the distillation is improved; the test range, sensitivity, and specificity are extended; and the determination of color change after oxidation is made by spectrophotometry. The recovery of alcohol is from 99 to 100%, averaging 99.7%. The mean, deviation between analyses on identical samples by different analysts in separate laboratories is 2.7% of the alcohol actually present (a mean absolute difference of ± 0.004% w/v ethyl alcohol). Alcohol-free blood and urine specimens consistently yield "blank" values less than 0.001% w/v alcohol; and acetone, chloral hydrate, chloroform, ethyl ether, lactic acid, and methenamine do not interfere in this analysis, although methanol and high concentrations of formaldehyde and of paraldehyde do react. The range of the method for a single analysis on unknown specimens is 0 to 0.61% w/v ethyl alcohol; however, higher alcohol concentrations in the original sample do not require a complete repeat analysis, since they can be determined by appropriate dilution of the remaining initial distillate. A single determination requires about 20 minutes. Up to five analyses per hour can be performed in series using a single distillation apparatus, and a single analyst can perform 8 to 12 determinations per hour by using two distillation units.

Harger Method

The Harger method[28] is as follows:

Principle.—Protein-free filtrates of blood, spinal fluid and tissues, and diluted urine are distilled from an all-glass still of small capacity. Alcohol in the distillate is oxidized to acetic acid by an accurately measured quantity of potassium dichromate in sulfuric acid at about 17 *N* acidity. The excess dichromate is accurately titrated with a standard solution of ferrous sulfate in the presence of methyl orange. The difference between this titration and that of a "blank" distillate containing no alcohol represents the quantity of dichromate used in the oxidation.

Apparatus

1. Distilling apparatus: 250-ml. round-bottom Pyrex flask and condenser of small capacity with straight glass condensing tube. The flask and condenser are connected, preferably, with standard taper ground-glass connections.

2. Volumetric flasks and pipettes: 5-ml. microburet graduated in 0.01 ml.

3. Beads or fragments of glass or Vitreosil to prevent bumping.

4. Reaction tubes: Pyrex test tubes, 25 by 200 mm., or 50-ml. Erlenmeyer flasks.

Reagents

1. Sodium tungstate, 10% w/v.
2. Sulfuric acid, 1/12 *N*.

3. Sulfuric acid, approximately 17 *N*: Pour, slowly with stirring, one volume of concentrated sulfuric acid into one volume of water; cool.

4. Sulfuric acid, concentrated.

5. Methyl orange, 0.1%: Dissolve 1 Gm. of methyl orange in 1 liter of approximately 0.025 *N* NaOH solution.

6. Ferrous sulfate solution: Place 50 Gm. of $FeSO_4 \cdot 7H_2O$, weighed to 0.1 Gm., in a 250-ml. volumetric flask containing 150 ml. of water. Carefully add 30 ml. of concentrated sulfuric acid; cool and dilute to the mark with water. Stopper and protect from light.

7. Ferrous sulfate–methyl orange standard solution: Into a 125-ml. Erlenmeyer flask, place 70 ml. of 17 *N* sulfuric acid, 30 ml. of 0.1% methyl orange solution, and exactly 2 ml. of ferrous sulfate solution. Two and one-half milliliters of this solution is equivalent to about 1 ml. of 0.0434 *N* dichromate. Standardize the solution each day. Keep the solution cool and prepare fresh solution after three or four days.

8. Standard potassium dichromate, 0.0434 *N*: Transfer 2.129 Gm. of C. P. potassium dichromate to a 1-liter volumetric flask. Dissolve in water and dilute to 1 liter. One milliliter of this solution is equivalent to 0.5 mg. of ethyl alcohol.

Procedure

1. Prepare the usual 1:10 protein-free tungstic acid filtrate, using 2 ml. or more of blood or spinal fluid, or 2 Gm. or more of minced tissue. For example, to 5 ml. of blood add 40 ml. of 1/12 *N* sulfuric acid, followed by 5 ml. of 10% sodium tungstate solution. Mix. Let stand a sufficient time, with occasional mixing, to allow complete diffusion of alcohol throughout the flask. Filter. Dilute urine tenfold with water. The alcohol in tissues is preferably removed by steam distillation.

2. Pipet 10 ml. of blood filtrate or diluted urine (representing 1 ml. of sample) into a 250-ml. flask. Add 40 ml. of water and a few glass beads or fragments. Connect the flask with the condenser and carefully heat the contents with a microburner flame. Collect almost 50 ml. of distillate through a condenser outlet which dips nearly to the middle of a 50 ml. glass-stoppered cylinder or volumetric flask. Dilute to the 50 ml. mark. Mix.

3. Pipet 10 ml. of the diluted distillate (representing 0.2 ml. or 0.2 Gm. of sample) into a 50-ml. Erlenmeyer flask or 25-by-200-mm. test tube. Add exactly 2 ml. of 0.0434 *N* dichromate solution and then 10 ml. of concentrated sulfuric acid. Mix well; cover with small beaker and allow to stand exactly 10 minutes. Cool in a bath of cold running water.

4. Simultaneously prepare several reagent blanks by substituting 10 ml. of distilled water for 10 ml. of distillate in step 3, using 1 ml. (titration B_1) and 2 ml. (titration B_2) of 0.0434 *N* dichromate.

5. Titrate the excess of dichromate with the ferrous sulfate–methyl orange reagent (in a microburet). The yellow color fades as the chromate ion is reduced. Then, when the first excess drop of reducing solution is added, the pink color of methyl orange fills the solution and makes a sharp end-point.

6. If the sample titration in step 5 is less than 0.2 ml., *repeat the distillation using* 5 *ml. of protein-*free filtrate or oxidize less than 5 ml. of original distillate by substituting distilled water for an appropriate portion of the distillate.

7. Standardize the procedure against specimens and aqueous solutions of known alcohol content.

Calculations.—Let B_1 and B_2=the blank titrations of 1 and 2 ml., respectively, of 0.0434 *N* dichromate (step 4), and let U=the sample titration (step 3). Further, let S=milliliters or grams of sample represented by the sample titration. Then, B_2-B_1=milliliters of ferrous sulfate solution equivalent to 1 ml. of the 0.0434 *N* dichromate. The difference between blank titrations is determined in order to correct for impurities in the water and reagents and for the extra drop to obtain the end-point. Hence $(B_2-U) \div (B_2-B_1)$=milliliter of 0.0434 dichromate required for the oxidation of alcohol. Since 1 ml. of the dichromate is equivalent to 0.5 mg. of ethanol,

$$\% \text{ alcohol in original sample} = \frac{0.5\ (B_2-U).}{10S\ (B_2-B_1)}$$

Critique.—This is perhaps the most widely used laboratory method. It requires simple and inexpensive apparatus. The distillation equipment permits rapid boiling and efficient recovery. The salient feature of the method is the final titration which has a sharp and distinctive end-point. The titration procedure is used in several other methods described in the literature. The range of concentrations of alcohol is up to 0.50% w/v; the speed of determinations and the recovery, specificity, and precision are within the same limits as those of the Dubowski procedure A described above.

Friedemann and Brook Method

The Friedemann and Brook method[10] is as follows:

Principle.—Blood, urine, or tissues are distilled directly or with steam from an acid–sodium tungstate–mercuric sulfate medium (removing volatile amines and some aldehydes, paraldehyde, and ketones). The distillate is redistilled from calcium hydroxide and mercuric sulfate (removing most phenols and the remaining aldehydes and ketones). The alcohols in the distillate are oxidized to the respective acids (formic, acetic, etc.) with potassium dichromate and sulfuric acid at about 2 *N* acidity. The volatile acids are quantitatively distilled from saturated magnesium sulfate solution. A portion of the distillate is titrated directly with standard sodium hydroxide; another portion is titrated after extraction with a measured volume of organic solvent, from which the distribution coefficient may be calculated. The two titrations identify and determine ethyl alcohol and higher alcohols. Methyl alcohol is determined quantitatively by titration of formic acid.

Apparatus

1. Distillation apparatus: All-glass, for direct and steam distillation similar to that used in the Dubowski and Harger methods. (Obtainable from Aloe Scientific Division, A. S. Aloe Co., 5655 Kingsbury Ave., St. Louis 12, Mo.)
2. Soda lime tower: Glass tube, 3 by 48 in., filled with soda lime between cotton plugs, used for aeration of distillates with carbon dioxide–free air.
3. Separatory funnel: Squibb separatory funnel, Pyrex glass, 250 ml. glass-stoppered.
4. Volumetric ware: Good grade of pipets, burets, and glass-stoppered volumetric flasks.

Reagents

1. Calcium hydroxide suspension: Slake 100 Gm. of pure calcium oxide with a minimum of water; add 1 liter of water. Keep the creamy suspension in a glass-stoppered bottle protected from dust.
2. Distilled water, free of volatile impurities.
3. Ethyl ether, anhydrous.
4. Magnesium sulfate.
5. Mercuric oxide, red powder.
6. Mercuric sulfate reagent, 10% w/v in 2 *N* sulfuric acid.
7. Potassium dichromate, powdered.
8. Sodium hydroxide, 0.10 *N* stock solution, protected from atmospheric carbon dioxide.
9. Sodium hydroxide, 0.010 *N*, freshly prepared from the 0.10 *N* stock solution with boiled, distilled water.
10. Sodium tungstate solution 10% w/v.
11. Sulfuric acid, 20 *N*.
12. Sulfuric acid, 10 *N*.

Procedure

1. Into a 500-ml. distillation flask containing 100 ml. of distilled water and 15 ml. of acid mercuric sulfate reagent, place 1 to 10 ml. of blood or urine (or 1 to 10 Gm. of finely ground tissue), 10 ml. of sodium tungstate solution, and some talcum. Mix contents thoroughly by rotation.

2. Distill rapidly until the volume has been reduced about one-half or more, collecting the distillate 1 in another 500-ml. distillation flask.

3. Add to this distillate 1, 10 ml. of acid mercuric sulfate reagent, 10 ml. of calcium hydroxide suspension, talcum, and enough distilled water to bring the volume to about 100 ml. If the sample contains paraldehyde, phenol, or other volatile substances than alcohols, the contents of the first and second distillation flasks should be well shaken and allowed to stand for at least 10 minutes before each distillation.

4. Distill the mixture, receiving 70 to 80 ml. of distillate 2 in a glass-stoppered 100-ml. volumetric flask. Add 10 ml. of 20 *N* sulfuric acid and an excess of powdered or dissolved potassium dichromate. Allow the well-mixed reaction mixture (which contains about 2 *N* acid) to stand overnight at room temperature, or heat for about 30 minutes in a boiling water bath and then cool.

5. Transfer the oxidation mixture to a 500-ml. distillation flask; add distilled water to bring the mixture volume to about 200 ml. Then add about 50 gm. of magnesium sulfate crystals and talcum. The magnesium sulfate reduces the acidity, prevents overoxidation when the volume becomes small, and greatly increases the volatility of the acetic and other acids. Distill the mixture and collect 180 to 190 ml. of distillate 3 in a 500-ml. distillation flask.

6. Aerate the distillate 3 with air from the soda lime tower to remove carbon dioxide and titrate the total volatile acids to the phenolphthalein endpoint with 0.01 *N* sodium hydroxide (titration A). (Aqueous sodium phenolphthaleinate is preferred to the alcoholic indicator solution.)

7. If the presence of methyl alcohol or other alcohols is suspected, treat the distillate 3, after titration A, with talcum, 2 ml. of 10 *N* sulfuric acid, 50 Gm. of magnesium sulfate, and 0.3 to 0.5 Gm. of mercuric oxide in that order; and redistill in 30 to 45 minutes, collecting the distillate 4 in a 250-ml. volumetric flask which is then made to the mark with distilled water. This quantitatively removes formic acid, which is produced in a constant 60% yield from methyl alcohol.

8. Titrate directly 100 ml. of distillate 4 with 0.01 *N* sodium hydroxide after aeration to remove carbon dioxide (titration B).

9. Extract another 100 ml. of distillate 4 with 50 ml. of ethyl ether in a 250-ml. Squibb separatory funnel, shaking for one minute or more. Draw off the aqueous phase and titrate it with 0.01 *N* sodium hydroxide (titration C).

10. The procedure may be considerably simplified, if it is known that only ethyl alcohol is present, by doing only two distillations and one titration, as follows, according to steps 1, 2, and 4 through 6: (*a*) distillation of alcohol from mercuric sulfate–tungstic acid, (*b*) distillation of volatile acids following oxidation, and (*c*) titration of total volatile acids by titration A.

11. In all sample titrations (A, B, and C) corrections for acids, if any, derived from reagents are made by titrations of blank distillates.

12. The procedure is standardized against aqueous solutions and blood containing known quantities of ethyl alcohol or other alcohols.

Calculation of Results.—The difference between titrations A and B determines the formic acid from oxidation of any methyl alcohol present. Titration B determines the volatile acids derived by oxidation from alcohols other than methyl alcohol. Titrations B and C determine the distribution constant $k=(C/B\times 100)$, which is characteristic for the acid derived from each alcohol and which represents the percentage of acid remaining in the aqueous phase. Thus the constant for acetic acid from ethyl alcohol, or the percentage of acid not extracted=86.5; for acids from propyl alcohol=70.0; for acids from butyl alcohol=49.0.

When titration A equals titration B, the sample contains no methyl alcohol. If, in addition, k is 86 to 87, the sample contains only ethyl alcohol.

Critique.—The distinctive feature of this method is the ability to identify and determine specifically ethyl alcohol and other alcohols which may be present in the sample. Most potential interferents are eliminated in the double distillation. With 2-ml. samples the minimum alcohol concentration at which the method is still reliable is about 0.050 ± 0.0015% ethyl alcohol or methyl alcohol and with 5-ml. samples about 0.020 ± 0.0006% (steps 1 through 6). The over-all recovery is within 99% in the four distillations of the complete procedure. The accurate range of the method is very wide, from 0.02 to about 1.0% of alcohol in the sample. The complete procedure is longer and more involved than the three previously described methods. A single determination requires about three hours. However, if the determination is limited to only two distillations and one titration (step 10), about 90 minutes are required for a determination.

QUALITATIVE TESTS FOR SOME COMMON INTERFERING SUBSTANCES

The identity and significant concentrations of possible chemical interferents vary with the particular method chosen for the determination of ethyl alcohol, depending on the relative specificity or selectivity of that method for ethyl alcohol. When present, such interference consists of the production of falsely positive apparent ethanol reactions, or of false elevations of a true ethanol level. The presence of significant concentrations of any potential chemical interferents, in body materials obtained from living subjects, is a comparatively infrequent occurrence, particularly when the subjects are conscious and well. It is even more unusual to find significant levels of two or more potential chemical interferents in a single biological material specimen from a living subject, in addition to ethyl alcohol. However, it is frequently necessary or desirable in forensic alcohol determinations to establish experimentally the absence of such potential interferents in significant concentrations in order to safeguard their probative value; and it is occasionally useful to search for the more common nonethanol volatile organic substances in clinical alcohol analyses conducted in connection with the differential diagnosis of coma states.

Among the volatile substances most commonly encountered in actual or suspected interference with some alcohol determination methods, when present in sufficient quantity, are acetaldehyde, acetone, formaldehyde, isopropyl alcohol, methyl alcohol, and paraldehyde. The following simple tests will generally suffice for indicating the presence or absence in body material specimens of concentrations of these six substances potentially capable of interference in some, though not all, ethyl alcohol determination methods. These screening tests are not intended to cover every substance potentially capable of chemical interference in some alcohol analysis, nor is inclusion of a test for a given substance an indication that it can or will interfere in any particular ethanol determination method.

Obviously, if these or other tests disclose the presence of significant levels of potentially interfering substances in a specimen to be analyzed for ethyl alcohol content, the possibility of such interference should be eliminated by choosing a method unaffected by the interferent(s) present or by adequately modifying the proposed alcohol procedure. Should this be impossible or impractical, or should the specimen appear unsuitable for alcohol analysis because of advanced decomposition, putrefaction, or especially great chemical contamination, it is generally preferable to forego that alcohol analysis rather than to jeopardize the validity of the results.

An important application of these screening tests is in clinical alcohol analysis practice under the following two conditions: (1) in the event of lack of concordance between a confirmed ethyl alcohol analysis result and the subject's physical condition, and (2) in comatose or seriously intoxicated subjects, to avoid a false sense of security based on, and a misleading clinical interpretation given to, a positive ethyl alcohol analysis result, in the presence of another unrecognized concurrent intoxication (e. g., by methyl alcohol).

Acetaldehyde Test

Acetaldehyde is detectable in biological materials and distillates by its distinctive pungent odor at concentrations below 0.01%, as is paraldehyde, which is hydrolyzed during distillation and appears in the distillate as acetaldehyde. The following chemical screening test identifies acetaldehyde in significant concentrations.

Reagents

1. Acetic acid, glacial, C. P.
2. Piperidine (hexahydropyridine).
3. Sodium nitroferricyanide, saturated solution, freshly prepared.

Procedure

1. To 1 ml. of unoxidized body material distillate in a small borosilicate glass test tube, add 1 drop of freshly prepared sodium nitroferricyanide solu-

tion to give a pale yellow color to the solution; then allow 1 drop of piperidine to flow down the side of the inclined tube. Shake the tube to mix the contents, and observe the resulting solution color.

2. Add 3 to 4 drops of glacial acetic acid; mix by shaking and observe for color changes.

Test Interpretation

Negative: A yellow to light brown color is obtained in step 1, which changes to a slightly lighter shade of yellow on addition of glacial acetic acid. (Formaldehyde does not react in this test.)

Positive: A green to deep blue color, depending on the concentration of acetaldehyde, is obtained within two minutes in step 1; it changes to deep green on addition of glacial acetic acid and then fades.

Sensitivity.—The test becomes positive at acetaldehyde concentrations of 0.005% or higher in the distillate.

Acetone Test

Acetone is readily detectable in body material distillates at concentrations considerably below those interfering in most alcohol determination methods, by use of commercial urine acetone test materials based on Rothera's test.

Reagent.—Acetest reagent tablets, containing aminoacetic acid, disodium phosphate, and sodium nitroferricyanide (catalog number 2381, Ames Co., Inc., Elkhart, Ind.).

Procedure

1. Place 1 Acetest reagent tablet on a clean piece of white paper. Place 1 drop of distillate on the tablet.

2. Observe the tablet for color changes after 30 seconds.

Test Interpretation

Negative: Tablet color remains unchanged or tablet becomes pale cream colored.

Positive: Tablet surface changes within 30 seconds to a color varying from light lavender to deep purple, depending on the acetone concentration present.

Sensitivity.—The test becomes positive at acetone concentrations below 0.01% in the distillate.

Formaldehyde Test

Formaldehyde is readily detectable in biological material distillates by a sharp recognizable odor even at low concentrations (below 0.02%) and is demonstrable by simple specific chemical tests at far lower levels.

Reagents

1. Chromotropic acid disodium salt: 4,5-dihydroxy-2,7-naphthalene-disulfonic acid disodium salt, Practical (catalog number P230, Distillation Products Industries Division, Eastman Kodak Co., Rochester 3, N. Y.).

2. Sulfuric acid, concentrated, C. P.

Procedure

1. To 1 ml. of biological material distillate in a small borosilicate glass test tube, add approximately 10 mg. of chromotropic acid disodium salt and mix thoroughly by shaking.

2. Add 1.5 ml. of concentrated sulfuric acid along the side of the inclined test tube so as to underlay the aqueous solution. Examine the interface for a purple or violet color.

3. Cautiously mix the tube contents by gentle swirling, and allow the tube to stand for approximately five minutes. Examine for presence of a diffuse purple or violet color.

Test Interpretation

Negative: Colorless or yellow color at the interface (step 2) and a colorless or yellow mixture (step 3). (Acetaldehyde does not react in this test.)

Positive: Presence of a purple or violet color at the interface (step 2) and a purple or violet color in the mixture (step 3).

Sensitivity.—The test becomes positive at formaldehyde concentrations below 0.00005% in the distillate.

Isopropyl Alcohol Test

Isopropyl alcohol can be identified in acetone-free body material distillates by a simple modification of Denigès' procedure,[3b] sensitive to concentrations below interfering levels.

Reagent.—Denigès' reagent: Suspend 2 Gm. of yellow mercuric oxide in 16 ml. of distilled water and, while mixing, add 8 ml. of concentrated sulfuric acid. Stir and dissolve with addition of another 16 ml. of distilled water.

Procedure

1. To 1 ml. of distillate in a small borosilicate glass test tube add 2 ml. of Denigès' reagent. Stopper the test tube and heat in a fluid bath at 100 C for 30 minutes.

2. Cool the tube and examine for presence of a white finely divided precipitate, centrifuging the tube if necessary.

Test Interpretation

Negative: No white precipitate or white turbidity is present.

Positive: A distinct white precipitate is present. (Acetone also yields a positive test and is ruled out by the acetone test described above.)

Sensitivity.—The test becomes positive at isopropanol concentrations of 0.005% in the distillate.

Methyl Alcohol Test

Methyl alcohol, which interferes in most ethyl alcohol determination methods, can be identified readily and, in the absence of formaldehyde, specifically at extremely low concentrations in biological material distillates by a simple modification of Eegriwe's chromotropic acid test for formaldehyde.

Reagents

1. Acid permanganate reagent: 3.0% potassium permanganate in 12.8% phosphoric acid (15 ml. of 85% syrupy phosphoric acid per 100 ml.).

2. Chromotropic acid disodium salt: 4,5-dihydroxy-2,7-naphthalene-disulfonic acid disodium salt, Practical.

3. Sodium bisulfite ($NaHSO_3$), C. P., powdered.

4. Sulfuric acid, concentrated, C. P.

Procedure

1. Into a small borosilicate glass test tube place 1 ml. of biological material distillate; add 0.1 ml. (approximately 2 drops) of acid permanganate reagent, shake well to mix, and allow to stand at room temperature for two minutes.

2. Add just enough powdered sodium bisulfite to decolorize completely the excess potassium permanganate and any brown manganese dioxide formed (approximately 5 to 10 mg.).

3. Add approximately 10 mg. of chromotropic acid disodium salt and shake gently to dissolve; then add 1.5 ml. of concentrated sulfuric acid, allowing the acid to flow down the side of the inclined test tube to form a separate layer below the aqueous solution. Examine the interface for presence of a purple or violet color.

4. Cautiously mix the tube contents by gentle swirling and allow the tube to stand for approximately five minutes. Examine for presence of a diffuse purple or violet color.

5. In all positive methyl alcohol tests, also test the unoxidized distillate for formaldehyde as described above.

Test Interpretation

Negative: Absence of a purple or violet color at the interface (step 3) or of a diffuse purple or violet color (step 4) indicates the absence of methyl alcohol and of formaldehyde. (The solution may be colorless or yellow to light brown.)

Positive: Presence of a purple or violet color at the interface (step 3) or of a diffuse purple or violet color (step 4) indicates the presence of methyl alcohol or of formaldehyde in the distillate, the color intensity being proportional to the concentration. (The presence of formaldehyde in the distillate can be ruled out by the formaldehyde test described above; i. e., by a negative result following steps 3 and 4 of this test performed on 1 ml. of unoxidized distillate.)

Sensitivity.—The test as described becomes positive at methanol concentrations of less than 0.0002% in the distillate.

Appendix B

PROCEDURES FOR ANALYSIS OF BREATH FOR ETHYL ALCOHOL

Alcometer

The Alcometer (originally called Alcoholometer) (fig. 1), developed by Greenberg and Keator,[9] is a fully automatic apparatus (manufacturer: Frederick G. Keyes, Inc., 243 Broadway, Cambridge, Mass.), based on use of the iodine pentoxide reaction of Haggard and Greenberg,[3] in which the cycle of events is controlled by a synchronous electric motor.

The major components of the analytical train are as follows (fig. 2): (1) a pump supplying room air to purge the instrument and to sweep the sample through the analytical system; (2) a silica gel drying tube no. 1 for drying incoming room air; (3) an iodine pentoxide reaction tube no. 1 to oxidize any interfering substances in the incoming room air; (4) a bulb, containing powdered copper, to absorb any liberated iodine; (5) a drying tube no. 2 to insure complete dryness of the purified room air; (6) a fixed volume sample chamber, with solenoid valves; (7) an iodine pentoxide tube no. 2 to oxidize any alcohol present in the breath sample; (8) a glass or plastic bubbler tube leading from the second reaction tube into the indicator solution; (9) an indicator solution vial containing starch–potassium iodine to react with any iodine released in the iodine pentoxide oxidation in tube no. 2; and (10) a photronic colorimeter consisting of two barrier layer photocells, a photometer lamp, and a microammeter calibrated directly in blood alcohol concentration.

In addition to the Alcometer, the following expendable materials are required for each test: one indicator vial containing 0.1% starch and potassium iodine solution in a vial which also serves as a photometer cuvette and one wood mouthpiece.

The analysis consists of four principal phases: (1) purging of the sample chamber and chemical train with purified room air; (2) collection of a measured volume of alveolar air; (3) pumping of the breath sample through the hot iodine pentoxide reagent bed and flushing of any liberated proportionate quantity of iodine vapor into the 0.1% starch indicator solution; and (4) measurement of the resulting blue color of the indicator solution with an integral photoelectric colorimeter, on which a reading, proportionate to the alcohol concentration of the breath sample, is obtained on a microammeter scale, calibrated directly in blood alcohol concentration.

Alcohol is oxidized as follows by the iodine pentoxide:

(*a*) $5C_2H_5OH + 6I_2O_5 = 10CO_2 + 15H_2O + 6I_2$

(*b*) $C_2H_5OH + I_2O_5 = 2CO_2 + H_2O + 2HI$

At a constant temperature and a constant rate of air flow, the yield of iodine is consistently proportional to the quantity of ethyl alcohol oxidized.

Various mechanical and electrical components operate the instrument through the proper sequence of steps according to predetermined timing; interlocks prevent untimely operation or omission or duplication of steps in the analysis. The initial warm-up of the instrument requires about 10 minutes, and a complete analysis thereafter requires about 8 minutes.

Alcotest

This portable device (fig. 3), developed by Grosskopf and Scheibe,[21] utilizes the vapor-in-air detector tube system of Grosskopf and employs potassium dichromate in sulfuric acid for oxidation of alcohol in mixed expired breath (manufacturer: Drägerwerk, Lübeck, Germany; U. S. distributor: Schueler and Company, 75 Cliff St., New York 38, N. Y.).

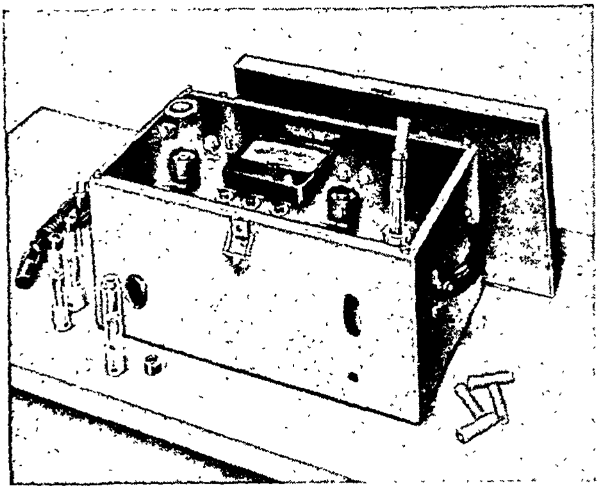

Fig. 1.—The Alcometer, model M-4.

A single test unit consists of an expendable sealed glass detector tube, an expendable plastic mouthpiece, and a sturdy plastic breath-measuring bag of 1 liter capacity. The detector tube is a 9.5-mm. diameter glass tube, 85 mm. long, containing a 15-mm. long reagent layer of silica gel impregnated with potassium dichromate in sulfuric acid solution held between glass wool plugs. A 1-mm. wide annular marking of yellow color approximating that of the reagent zone before the test encircles the tube in the middle of the reaction layer. Alcohol is oxidized as follows:

$$2K_2Cr_2O_7\ (\text{yellow}) + 8H_2SO_4 + 3C_2H_5OH = 2Cr_2(SO_4)_3\ (\text{green}) + 2K_2SO_4 + 3CH_3COOH + 11H_2O$$

The reaction is accompanied by a color change from the yellow of the potassium dichromate to the green of the chromic sulfate, the width of the green zone being roughly proportional to the breath alcohol concentration. The approximate lower sensitivity of the original test is at about 0.08 mg. of alcohol per liter of tested air (corresponding in this test system to about 0.03% w/v blood alcohol), and the maximum recognizable upper test range is at about 0.5 mg. of alcohol per liter (corresponding to about 0.17% w/v blood alcohol). In accordance with the suggestions of one of us (K. M. D.), a special Alcotest 1.5 unit was later developed for United States practice.

The flow resistance of the tube (1 liter per minute at 35 to 55 mm. H_2O pressure) is such that in actual use 1 liter of expired breath is generally forced through in about 15 seconds, requiring the test subject's full lung pressure and preventing aspiration and admixture of room air. The absorbed water vapor from the breath reacts with the concentrated sulfuric acid in the reagent layer to produce a temperature of about 80 C, which increases the speed of the reaction and heats the glass reaction tube sufficiently to prevent condensation of breath prior to its passage through the reagent zone.

The test operation consists of three steps: 1. Both ends of the detector tube are cut off. A plastic mouthpiece is placed on one end, and the other end is inserted (in the direction indicated by an arrow on the tube) into the plastic air inlet of the completely deflated plastic bag for collecting and measuring 1 liter of air. 2. The 1-liter test bag is inflated by the subject with mixed expired breath through the mouthpiece and detector tube, if possible with a single breath, in not more than 20 seconds. 3. The reaction zone of the detector tube is examined to determine whether any discoloration of the originally yellow reagent layer to green has occurred, and if so its extent.

Fig. 2.—Schematic diagram of the Alcometer.

Rough semiquantitative interpretation of any color change noted in the Alcotest 1.5 detector tube can be made as follows: At no discernible green discoloration the probable blood alcohol level of the test subject is less than 0.05% w/v. A green coloration of the reaction zone up to the yellow marking ring (about 8 mm.) indicates a probable blood alcohol level of 0.05 to 0.15% w/v. A green coloration of the reaction zone beyond the yellow comparison ring indicates that the probable blood alcohol level of the test subject is above 0.15% w/v.

A complete test requires about one minute. The test materials are packaged in a small cardboard carton containing 10 detector tubes, 10 cellophane-wrapped sterilized plastic mouthpieces, an ampul-tip breaker, and one plastic breath-measuring bag, together with a direction booklet and a color comparison chart. The shelf life of the unit is stated to be at least two years.

The Alcotest is designed only for use as a preliminary breath alcohol screening test.

Breathalyzer

The Breathalyzer (fig. 4) (distributor: Stephenson Corporation, Red Bank, N. J.) was developed by Borkenstein[25] and utilizes potassium dichromate in sulfuric acid solution as the reagent for oxidizing alcohol in alveolar air. The operation consists of four principal phases (fig. 5): (1) flushing of the apparatus with room air; (2) collecting a measured volume of alveolar air; (3) passing the breath sample through potassium dichromate–sulfuric acid solution in an ampul-cuvette and allowing oxidation to proceed; and (4) measuring the resulting color change of the reagent with an integral photoelectric filter photometer. The increased light transmission through the test ampul, resulting from the color change from the yellow of the dichromate to the green of the chromic sulfate, is measured with a balanced electrical circuit from two photovoltaic cells, using the Bunsen principle. A light bulb is mounted on a movable carriage between the ampuls, and the distance the light must be moved to reestablish the original photometric balance between light transmission through the ampuls prior to analysis is registered by the movement of a coupled pointer across a scale calibrated directly in blood alcohol concentration.

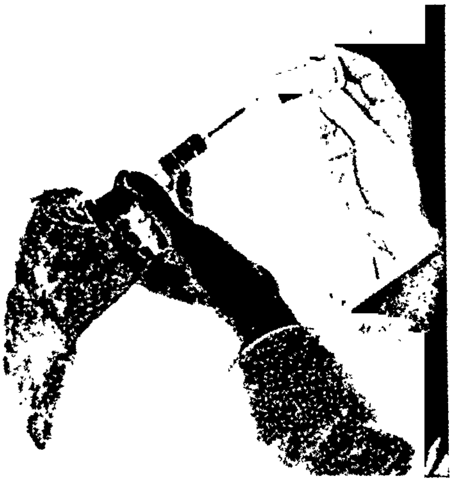

Fig. 3.—The Alcotest unit.

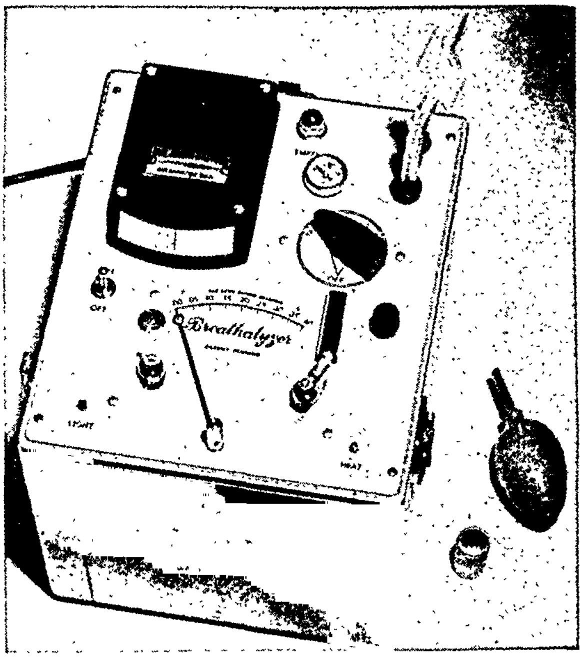

Fig. 4.—The Breathalyzer.

In addition to the Breathalyzer apparatus in its self-contained aluminum carrying case, the following expendable materials are required for each test: (1) two Breathalyzer reagent ampuls containing 3.0 ml. of 0.025% potassium dichromate in 50 vol.% sulfuric acid (one ampul serves as a photometric standard and is reusable; the ampuls also serve as photometer cuvettes), (2) one glass capillary bubbler tube for delivering the breath sample into the reagent ampul, and (3) a plastic mouthpiece and saliva trap.

A complete analysis requires about 6 minutes, and the initial warm-up of the instrument requires about 20 minutes. The Breathalyzer is designed for quantitative breath alcohol determination.

Drunkometer

The Drunkometer (fig. 6) (distributor: Stephenson Corporation, Red Bank, N. J.), developed by Harger and associates,[8] is a portable apparatus which also incorporates provisions for performing a rapid semiquantitative breath alcohol screening test. Potassium permanganate in sulfuric acid solution is used to quantitate the alcohol from samples of mixed expired breath or rebreathed air.

The apparatus consists of the following main components (fig. 7): (1) a rubber balloon for collection of the breath sample; (2) the alcohol reaction unit, consisting of an ampul containing sulfuric acid and potassium permanganate, connected to the balloon through a glass capillary tube and mounted in front of an electrically illuminated window between two color comparison standards in similar ampuls; (3) a breath-quantity measuring system consisting of a two-way valve, a water displacement gasometer, and an alternate chemical train of a moisture-absorbing tube of Dehydrite (an anhydrous granular magnesium perchlorate, supplied by Arthur H. Thomas Co., Philadelphia 5, Pa.) and a carbon dioxide–absorbing tube of Ascarite (a sodium hydroxide asbestos absorbent, supplied by Arthur H. Thomas Co., Philadelphia 5, Pa.).

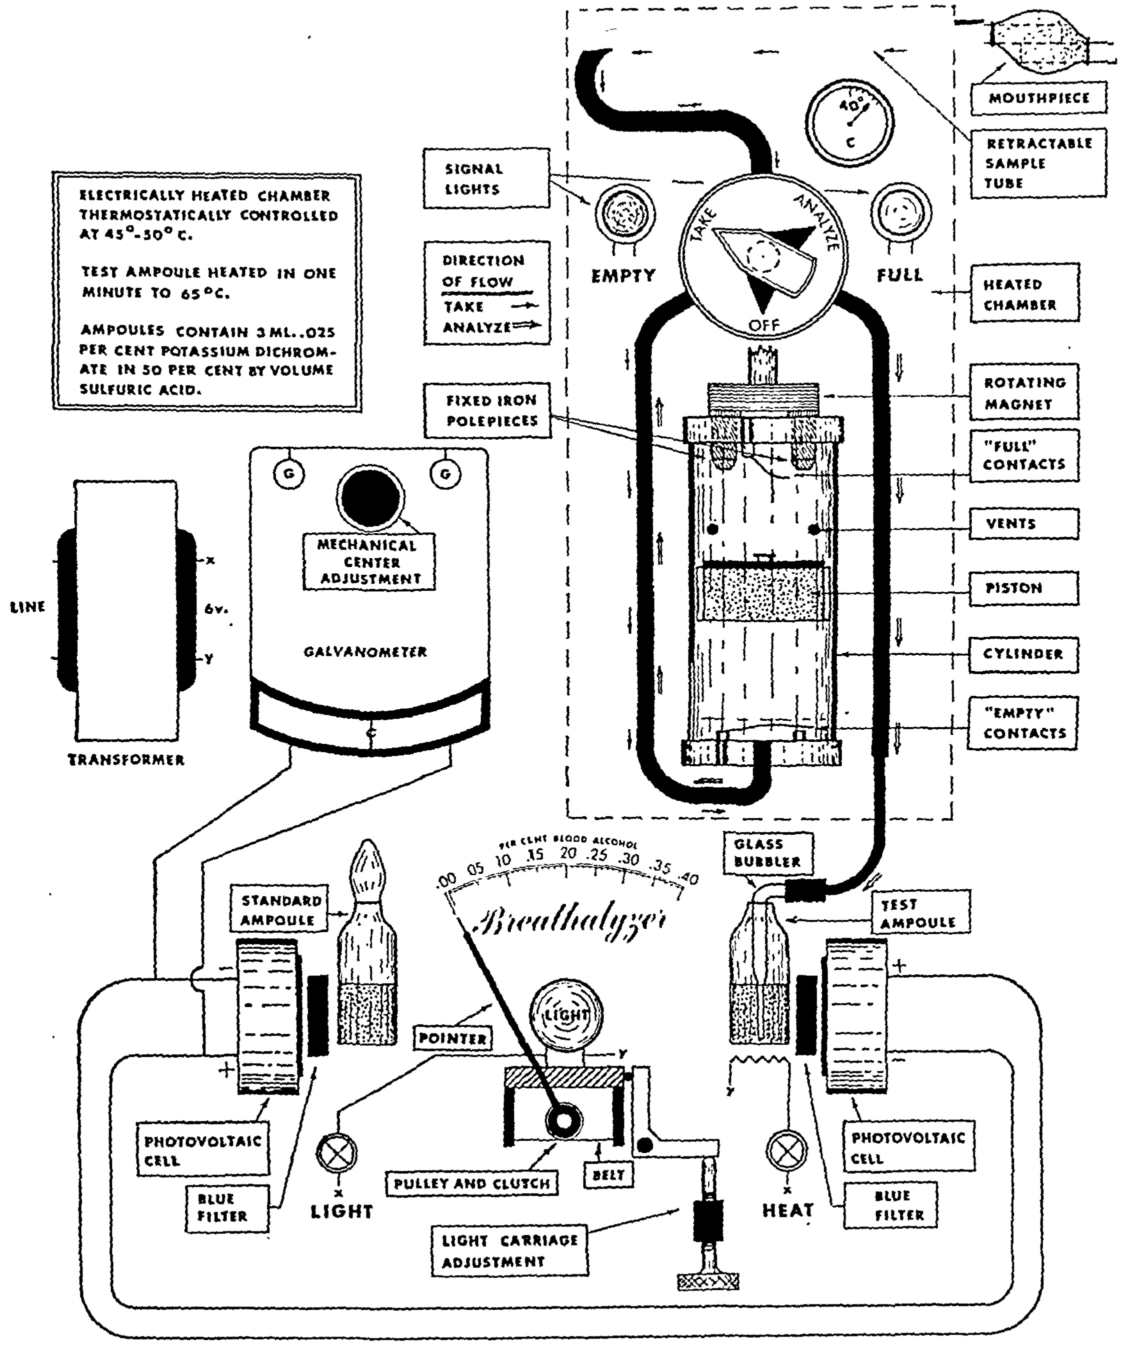

Fig. 5.—Schematic diagram of the Breathalyzer.

In addition to the self-contained apparatus, the following expendable materials are required for each test: (1) a rubber balloon with wood mouthpiece; (2) a sealed glass ampul reaction tube containing 10 ml. of 16 N sulfuric acid, to which 1.0 ml. of $N/20$ potassium permanganate solution is added immediately prior to an analysis; and (3) a 4-mm. glass inlet bubbler tube with rubber sleeve for making gas-tight connections between the ampul, the breath inlet tube, and the gasometer.

The Drunkometer can be used as a preliminary rapid semiquantitative screening test employing mixed expired breath or for quantitative determinations employing mixed expired breath or rebreathed air. In each instance, a fixed quantity of ethyl alcohol (0.169 mg.) is measured and the volume of mixed expired breath or rebreathed air required to furnish this quantity of alcohol is determined by direct water displacement, or the volume of alveolar air is calculated from the weight of carbon dioxide absorbed.

The analysis consists of the following major phases: (1) collection of a suitable breath sample by inflation of a rubber balloon with mixed expired breath or rebreathed air; (2) passage of the sample through the alcohol reagent in the ampul reaction tube until the original purple permanganate color has reached a pink-yellow end-point intermediate between the pink and yellow color standards, or until about 2,000 ml. of breath have passed through the apparatus (indicating a probable blood alcohol level of not more than 0.03%); (3) measurement of the breath volume required to reach the end-point (and which, therefore, contained 0.169 mg. of ethanol) by one of the following procedures: 1. Semiquantitative ("volumetric") test using mixed expired breath and quantitative determination using rebreathed air: The breath after leaving the reaction ampul passes directly to the graduated gasometer, where it displaces an equal volume of water. The breath volume used is read directly from the gasometer. 2. Quantitative determination using mixed expired breath: The breath after leaving the reaction ampul passes through the Dehydrite and through the previously weighed Ascarite tube, which absorbs the carbon dioxide present and is later reweighed to determine the carbon dioxide quantity absorbed during the test.

Calculations.—Since in all three variations of the tests (table 3), the quantity of alcohol required to reach the end-point (0.169 mg.) is identical, only the breath volume used for each test needs to be determined to supply the basic information concerning breath alcohol concentration. This is, in turn, converted to blood alcohol concentration using the observations that the weight of alcohol present in 1 ml. of blood is equal (*a*) to that present in about 3,200 ml. of mixed expired breath after removal of carbon dioxide and collection over water at 25 C or (*b*) to that present in 2,100 ml. of alveolar breath or in 2,100 ml. of rebreathed air or (*c*) to that accompanying 190 mg. of carbon dioxide from mixed expired breath or from alveolar breath. A complete "volumetric" Drunkometer test requires about 5 to 8 minutes; the complete quantitative determination requires about 10 minutes, including time for weighing the Ascarite tube before and after the test.

Drunkotester

The portable Drunkotester (manufacturer: Komyo Chemical Industrial Co., Ltd., Meguro, Tokyo, Japan; distributor: Kongo Shoji Kaisha, Ltd., Central P. O. Box No. 1253, Tokyo, Japan), developed by Kobayashi and Kitagawa, utilizes potassium dichromate in sulfuric acid solution to oxidize the alcohol in mixed expired breath.

The equipment consists of an expendable rubber balloon, an expendable sealed glass alcohol detector tube, a metal piston pump with two-way valve measuring 50 ml. per piston stroke, and a comparison chart—all contained in a small metal carrying case. The detector tube is a 4-mm.-diameter glass capillary tube, 12 cm. long, containing five narrow reagent zones of silica gel impregnated with potassium dichromate in sulfuric acid solution which are separated by 1 cm. long layers of powdered glass.

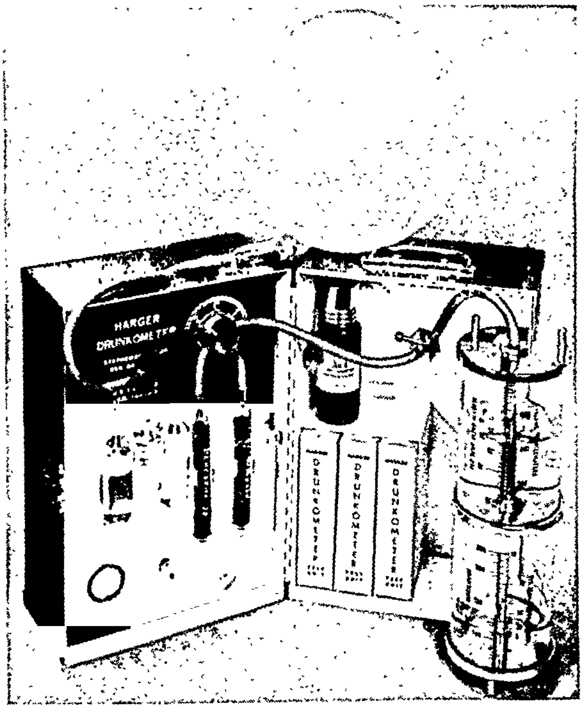

Fig. 6.—The Drunkometer.

In the operation, the ends of the glass detector tube are cut off and a rubber balloon is inflated by the subject with mixed expired breath. One end of the detector tube is inserted into the rubber balloon outlet, the other into the pump inlet opening. The pump valve is opened and 50 ml. of breath are aspirated from the ballon through the detector tube in approximately 15 seconds. The pump valve is then reversed; the piston is returned to the initial position; the valve is reopened, and another 50-ml. breath sample is aspirated through the detector tube. The tube is then disconnected and warmed briefly over an open flame (burner, match, cigarette lighter, etc.). The number of reagent zones which have changed from their original yellow color are noted by comparison with an unused tube, and the color intensity of the several changed zones (various shades of orange, green-yellow, and blue-green) is compared with a color chart depicting 12 tubes in various stages of change corresponding to blood alcohol levels of 0.00 to 0.42% in steps of 0.03 or 0.04%. A complete test requires about three to five minutes.

Intoximeter

The Intoximeter (fig. 8) (manufacturer: Intoximeter Association, 334 Buffalo Ave., Niagara Falls, N. Y.), developed by Jetter, Moore, and Forrester,[26] is a portable device for quantitatively absorbing both alcohol and carbon dioxide from exhaled breath which may be obtained in the field and later analyzed in the laboratory, combined with an integral system for performing a preliminary on-the-spot breath alcohol screening test.

The breath collection system is based on the organic vapor-absorbing properties of magnesium perchlorate. In principle, the method depends on the complete absorption of alcohol and of water vapor from a mixed expired breath sample by magnesium perchlorate, followed by the quantitative absorption of carbon dioxide by Ascarite.

Each unit is usable for a single test and can be recharged with chemicals for reuse. The main components of the Intoximeter are as follows (fig. 9): (1) a rubber balloon for initial collection and temporary storage of the breath sample; (2) a field test unit used as a screening test and consisting of a glass tube containing a fritted glass disk charged with sulfuric acid and potassium permanganate, connected to the balloon; and (3) a quantitative test unit, consisting of a train of two tubes, containing respectively magnesium perchlorate and Ascarite.

The operations in the field consist of three steps: (1) collection of a sample of mixed expired breath by inflation of the rubber balloon; (2) passage of a small portion of the collected breath through the field test unit containing an acid potassium permanganate solution (a portion of any alcohol present in the breath reacts with the acid permanganate, destroying its original purple color in a time interval roughly inversely proportional to the breath alcohol [and therefore the blood alcohol] concentration); (3) successive passage of the remaining sample through the magnesium perchlorate tube and the preweighed Ascarite tube for later quantitative laboratory analysis. (The former tube quantitatively absorbs any alcohol and all water vapor present in the breath; the latter quantitatively absorbs the carbon dioxide.)

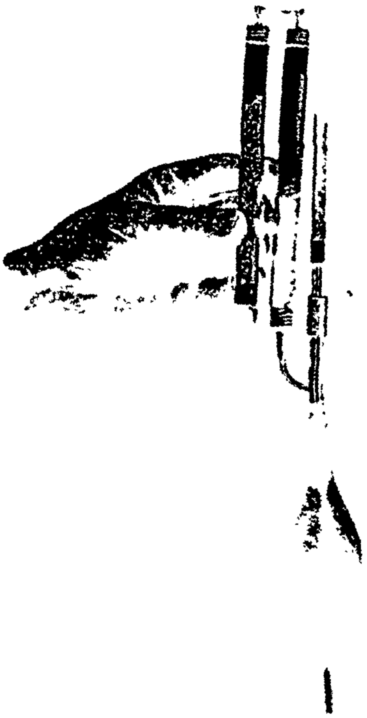

Fig. 8.—The Intoximeter.

After these initial steps the entire Intoximeter is returned to a suitably equipped laboratory, where the quantity of absorbed alcohol is distilled and determined by the Harger[5] or other suitable laboratory test and the Ascarite tube is reweighed, yielding the weight of carbon dioxide from the increase in weight over that before the test. From the analysis of alcohol and carbon dioxide, the blood alcohol concentration is calculated on the basis of the observation that the weight of alcohol present in 1 ml. of blood is equal to that accompanying 190 mg. of carbon dioxide in the mixed expired or alveolar breath.

Performance of the on-the-spot field test and breath collection usually requires about five minutes.

The Intoximeter Association has announced the development of a "photoelectric intoximeter" which is stated to employ an alveolar air sample and potassium dichromate in sulfuric acid solution as the oxidizing reagent for quantitative breath alcohol analysis and to incorporate provisions for the simultaneous collection of a second alveolar air sample for subsequent confirmatory laboratory analysis.

THE HUMANITIES IN MEDICINE

GUEST EDITORIAL

Amos R. Koontz, M.D.

THE physician has long been looked on as a special sort of person in our society. The best of the profession have always been leaders in their communities. The repute in which the physician has been held was eloquently stated in Robert Louis Stevenson's tribute to him: "He is the flower of our civilization, and when that stage of man is done with, only to be marveled at in history, he will be thought to have shared but little in the defects of the period and to have most notably exhibited the virtues of the race."

For generations the best of our physicians have been educated not only in the science of their times but also in the humanities. However, there was a time when some of our medical schools were "proprietary schools," which did not require even a grammar school education as a prerequisite to study medicine. About 50 years ago that deplorable situation changed as a result of the well-known Flexner report and the American Medical Association's simple device of classifying schools as A, B, and C schools. Many schools which could not stand the publicity of their lower classifications went out of existence, thus reducing the number by more than half. We now have standard minimal entrance requirements, and the general educational average of the entering student is far superior to what it had ever been before this change was made.

In spite of the better education offered today the comment is often heard that the medical manuscripts are dull and boresome in comparison to those of 50 years ago. Few physicians today write as Osler did. Welch's lectures were erudite and Lewellys F. Barker was gifted with a flow of English such as few people have attained. Other examples could be cited. What has caused the difference?

In some of our select medical societies, one hears prominent men use poor English and pronunciation so bad that the listener is distracted from the content of the paper. There are probably two reasons for this.

First, our secondary education has deteriorated, except in the best private schools and the exceptional public school. Superintendents of public instruction and school boards have required teachers to take courses (mostly repetitious) in education, *in order to become "qualified" and to be advanced.* The stress has been on method instead of content. Not only are some of these courses useless but they hinder the acquisition of a real education in such fundamentals as mathematics, history, the languages, and science. This trend has been carried over into our colleges, where, with the number of "snap" elective courses offered, it is possible to graduate and still be an ignoramus. This is not the fault of our youth but of the type of educational processes to which they are exposed.

Young persons who are going to study medicine must have a more serious outlook on educational problems than the average student. But many youngsters do not decide to study medicine until they are well along in college and often not until they are through. If they have not taken the solid courses and skipped the froth along the way, they will not be prepared for medicine.

About the time of World War I, "premedical" courses were instituted, to insure that those who were to study medicine would be properly grounded in the fundamental sciences they would need to understand the medical sciences. As time went on and competition for entrance to medical schools became keen, these courses "backfired," resulting in the average student entering medical school with a far more limited fundamental education than a physician should have. As medical schools stressed science in entrance requirements, the premedical student loaded up on science and often completely neglected the humanities. Some medical schools now (belatedly) are concerned about this and deplore that their entering students have not a well-rounded education. If physicians are to take the social and cultural positions in their communities which is the ideal of our profession, every one who is to study medicine should be liberally educated in both the sciences and the humanities. Once this is accomplished, medical schools need not worry about the fundamental education of the students whom they select for admission, and the medical public need not worry about the diction of speakers at medical meetings or the lucidity of papers in medical journals.

In the meantime, we have on our hands a whole generation of physicians who entered medical school qualified in science but not in the humanities. Must such physicians sit and bemoan their fate? Certainly not. By properly selected reading, they can still broaden their education. But when is a practitioner, busy with patients, staff meetings, committee meetings, the medical literature, medical meetings, and writing papers, to have time for outside reading. The answer is utilization of scraps of time. There should always be nonmedical reading material on the bedside table. A few minutes to half an hour may be utilized before the lamp is turned off. A good book should be at hand when one is waiting for trains and planes and every overnight bag should contain one. And don't waste time looking out the window—grab a book. The more comprehensive a man's education, the better physician he will be. He is thereby given more of the human touch.

"In no profession does culture count for so much as in medicine, and no man needs it more than the general practitioner, working among all sorts and conditions of men, many of whom are influenced quite as much by his general ability, which they can appreciate, as by his learning of which they have no measure. The wider and freer a man's general education the better practitioner he is likely to be, particularly among the higher classes to whom the reassurance and sympathy of a cultivated gentleman of the type of Eryximachus, may mean much more than pills and potions." Osler said that.

CARDIAC RESUSCITATION IN MYOCARDIAL INFARCTION

Sudden death may occur in the early stage of acute myocardial infarction as a result of either ventricular standstill or ventricular fibrillation. A few such patients with recent myocardial infarction have been saved, where quick and heroic action together with fortunate circumstances were responsible for resuscitation with cardiac massage during the critical four-minute period.[1] It would seem that the time has come when a greater number of deaths from ventricular fibrillation or standstill could be prevented by planned readiness for such emergency resuscitation of patients admitted to the hospital with a diagnosis of recent myocardial infarction. Fortunately, in some patients with acute or impending myocardial infarction a warning develops in the form of bouts of premature beats or advanced atrioventricular block before the fatal change in cardiac mechanism sets in. Consideration should be given to placing patients in the acute stage of myocardial infarction routinely under continuous electrocardiographic observation with a monitoring system for excessive slowing or acceleration of the ventricular action; thus it might be possible both to recognize in time the patient who is in immediate danger of developing a fatal disturbance of cardiac rhythm and to foresee whether he is threatened by ventricular standstill or ventricular fibrillation. New methods for the treatment of the former have become available. An external pacemaker for electric stimulation of the heart[2] has been used successfully under such circumstances[3] and may now be replaced by the newly developed transistor pacemaker with percutaneous insertion of a myocardial electrode.[4] It is to be expected that a similar device, which would eliminate the need for thoracotomy, will be perfected for defibrillation of the ventricles, although rhythmic manual compression ("massage") may still be necessary in certain cases to restore and maintain pumping action until resumption of spontaneous coordinated heart action.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. Include the address label clipped from your latest copy of The Journal, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

COUNCIL ON NATIONAL DEFENSE

ARMY MEDICAL SERVICE PRESENTS MASS CASUALTY CARE CONCEPTS AND TECHNIQUES

The seventh annual National Civil Defense Conference will be held in Atlantic City on Saturday, June 6, immediately prior to the opening of the annual American Medical Association convention. "The one-day program will highlight medical problems involved in nuclear warfare," said Dr. Harold C. Lueth. "The program . . . will dramatize the important fact that the medical and health professions can take positive action to minimize the impact of mass casualties if properly trained and organized." Dr. Louis M. Orr will open the conference. Physicians attending the meeting will get a one-day version of the Army's one-week education and training program dealing with mass casualty concepts and treatment techniques.

The general methods of instruction for these courses include lectures, student participation, group and panel discussions, visual aids, and manikin demonstrations. Currently, the courses are being given at Walter Reed Army Medical Center in Washington, D. C., and Brooke Army Medical Center in San Antonio, Texas. The courses embrace both the short-term and long-term expected injuries. Counter medical and health measures are stressed to combat the nuclear effects of blast, burn, and radiation injuries, both from the preventive and curative standpoint. All information pertaining to registration may be obtained from Frank W. Barton, Secretary, Council on National Defense, American Medical Association, 535 N. Dearborn St., Chicago 10.

Morning

8:00-9:00	Registration
9:00-9:05	**Call to Order and Introductory Remarks** Harold C. Lueth, M.D., Chairman, Committee on Disaster Medical Care, Council on National Defense, A. M. A.; Member, Council on National Defense, A. M. A., Evanston, Ill.
9:05-9:15	**Welcome Address on Behalf of A. M. A.** Louis M. Orr, M.D., President-Elect, A. M. A., Orlando, Fla.
9:15-9:25	**Introduction to Army Medical Service Course on Management of Mass Casualties** The Surgeon General, Department of the Army.
9:25-9:40	**Graphic Presentation of Situation**
9:40-10:10	**Casualty Estimation and Analysis** Major Jack C. Fitzpatrick, MC, USA, Nuclear Medical Officer, Office of the Assistant for Nuclear Warfare, Instruction and Casualty Studies, Army Medical Service School, Brooke Army Medical Center, Fort Sam Houston, Texas.
10:10-10:45	**Casualty Demonstration** Lieut. Col. Vincent I. Hack, MSC, USA, Army Medical Service School, Brooke Army Medical Center, Fort Sam Houston, Texas.
10:45-11:00	BREAK
11:00-11:20	**First Aid: Survival Care** Lieut. Col. Joseph D. Goldstein, MC, USA, Chief, Department of Atomic Casualties Studies, Walter Reed Army Institute of Research, Washington, D. C.
11:20-11:30	**Discussion of Emergency Medical Packet for 100 Casualties** Col. Theodore M. Carow, MC, USA, Chief, Supply Division, Office of the Surgeon General, Department of the Army, Washington, D. C.
11:30-12:00	**Sorting and Establishment of Priorities** Lieut. Col. H. Haskell Ziperman, MC, USA, Director, Department of Military Medicine and Surgery, Army Medical Service School, Brooke Army Medical Center, Fort Sam Houston, Texas.

Afternoon

12:00-12:30	**Management of Burns Resulting from Nuclear Disaster** Lieut. Col. Edward H. Vogel, MC, USA, Commanding Officer, Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston, Texas.
12:30-1:00	**Management of Soft Tissue Trauma** Lieut. Col. William H. Moncrief Jr., MC, USA, Director, Division of Surgery, Walter Reed Army Institute of Research, Washington, D. C.
1:00-2:15	LUNCH
2:15-2:45	**Preventive Medicine in Disaster: Public Health Aspects** Col. Philip R. Beckjord, MC, USA, Assistant Chief, Preventive Medicine Division, Office of the Surgeon General, Department of the Army, Washington, D. C.
2:45-3:15	**Chemical and Biological Warfare** Col. William D. Tigertt, MC, USA, Commanding Officer, United States Army Medical Unit, Fort Detrick, Md.
3:15-3:30	BREAK
3:30-3:45	**Impact of Radioactive Fall-out on Medical Operations** Col. Roy D. Maxwell, MSC, USA, Assistant for Nuclear Warfare Instruction and Casualty Studies, Army Medical Service School, Brooke Army Medical Center, Fort Sam Houston, Texas.
3:45-4:15	**Psychological Aspects of Disaster** Col. Albert J. Glass, MC, USA, Chief Psychiatry and Neurology Consultant, Office of the Surgeon General, Department of the Army, Washington, D. C.
4:15-5:00	**Panel Discussion—Question Period**

MEDICAL NEWS

ALASKA

Rise in Radioactivity.—During the first six weeks of 1959 air sampling stations at Juneau, Anchorage, and Fairbanks all measured radioactivity, which rose to about 10 micromicrocuries per cubic meter of air according to reports received by March 1 at the Alaska Department of Health radiological office in Juneau. When the first monitoring station of Alaska's radiation surveillance network went into operation at Juneau in May, 1956, the background radioactivity was measured at 0.15 to 0.25 micromicrocurie per cubic meter of air. The highs recorded in Juneau between Jan. 1 and Feb. 17, were 11.4 on Jan. 5, 5.9 on Jan. 26, and 9.3 on Feb. 9. In Anchorage the reading on Jan. 16 was 7.6, after which it went up to 8.7 on Jan. 23 and 9.2 on Jan. 26. In Fairbanks the highest reading for the period was 10.5 on Jan. 26. The readings are the USPHS Washington laboratory results obtained from 24-hour air samples made in Alaska by using 4-inch dust filters and indicating beta activity in comparison with a 0.02 microcurie radioactive strontium standard.

CALIFORNIA

Program for Teaching and Research.—Under a $255,000 grant from the Russell Sage Foundation, Stanford Medical School will establish a new teaching and research program that combines social sciences with medicine. Students and faculty of the Medical School and of the departments of sociology, psychology, and anthropology will collaborate. The program will begin next fall when the medical school moves into its new 20-million-dollar center on the campus. The Russell Sage grant will provide basic support for the first five years. It will finance a beginning staff, student fellowships, and research. Nurses, social workers, and other members of the health team are expected to join the program eventually. Plans were developed from studies supported by an earlier grant from the foundation. The planners included Associate Dean Lyman M. Stowe of the Medical School, and professors Rodney R. Beard, of preventive medicine, Thomas A. Gonda, of psychiatry, and Edmund H. Volkart, Ph.D., of sociology. Professor Volkart will direct the program during its first year. It will emphasize interdepartmental teaching and research and will supplement health teaching and research along current lines.

ILLINOIS

Chicago

Annual I. F. Volini Lectureship.—This lectureship, presented annually under the auspices of the Phi Sigma of Phi Chi, of which fraternity Dr. Volini was a member, was given April 6 by Dr. Edward Compere, Northwestern University Medical School, on "The Stimulation or Retardation of Bone Growth."

English Anatomist to Lecture.—The 1959 Solomon Theron De Lee Lecture will be given by Prof. Sir Solly Zuckerman, C.B., F.R.S., department of anatomy, The Medical School, The University of Birmingham, England, on "The Control of the Gonadotrophic Functions of the Pituitary" in Dora De Lee Hall, The Chicago Lying-In Hospital, University of Chicago, 5841 Maryland Ave., Thursday, May 7, 4:30 p. m.

University News.—Dr. Andre Michel Lwoff, French authority on microbiology, presented a medical lecture at the University of Chicago entitled "Factors Influencing the Evolution of Viral Diseases at the Cellular Level in the Organism," sponsored by the E. R. Squibb and Sons Centennial Lecture Program. Dr. Lwoff has been with the Pasteur Institute, Paris, since 1921 and has been head of the department of microbial physiology since 1938.

Dr. Hasegawa to Receive Fellowship.—Dr. Junji Hasegawa has been named to receive the 1959 Gillette-Toni Fellowship for dermatologic study at the Northwestern University Medical School. This is the second straight year Dr. Hasegawa has been honored with this award by the fellowship committee at Northwestern. He will conduct research in dermatology under the direction of Dr. Herbert Rattner, chairman of the school's dermatology department. The fellowship grant totals $4,000, of which $2,500 is paid to Dr. Hasegawa with an additional $1,500 given to the university to defray tuition and departmental overhead expenses.

Break Ground for Diagnostic Center.—Groundbreaking ceremonies for a $1,980,000 Diagnostic Center Building at University of Chicago Clinics were held April 14. The new building, to be located at 59th Street and Drexel Avenue, will provide a central location to serve the 200,000 outpatient visitors to the clinics each year. The Diagnostic Center Building will be accessible to the Univer-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

sity of Chicago hospital group's 36 clinical areas. Maurice Goldblatt, chairman of the University of Chicago Cancer Research Foundation, and John I. Kirkpatrick, vice-chancellor of the University of Chicago, gave addresses at the ceremonies, after which Dr. Lowell T. Coggeshall, dean of the division of biological sciences of the University of Chicago, spoke at a luncheon.

Lectures on Surgical History.—Two lectures on surgical history will be presented at the International College of Surgeons Hall of Fame on May 5. Dr. Francis L. Lederer, head, department of otolaryngology, University of Illinois College of Medicine, will speak on "The Evolution of Otorhinolaryngology and Bronchoesophagology." Dr. Wayne B. Slaughter, chairman and professor in charge of plastic surgery, University of Wisconsin, Madison, and Stritch School of Medicine, Loyola University, will speak on "The History of Plastic Surgery." The lectures are open to physicians, medical personnel, and the public. Information may be had by writing Dr. Ross T. McIntire, Executive Director, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10.

INDIANA

Surgeons Meeting in Indianapolis.—The Indiana Division, U. S. Section, International College of Surgeons, will hold its annual regent's meeting at the Indiana University Medical Center, Indianapolis, May 6. Papers to be presented include "Indications for Surgery of Peptic Ulcer, and Surgical Procedures Advised," by Dr. Claude J. Hunt, Kansas City, Mo., and "Types of Colostomies and Indications," by Dr. Peter A. Rosi, professor of surgery, Cook County Graduate School, and associate professor, Northwestern University, Chicago. The banquet at the Sheraton-Lincoln Hotel (Travertine Room) will be highlighted by a talk on "Sputniks, Space, and You" by Robert J. Dryter, consulting engineer. All surgeons, medical practitioners, their ladies, and guests are invited. For information write Dr. Simon Reisler, 318 Bankers Trust Bldg., Indianapolis.

KENTUCKY

Physicians Over 85 Still Active.—Four physicians, all over 85 years of age, are still actively practicing medicine in Morganfield. Combined they have a total of 223 years of medical experience. They are Dr. John W. Conway, who has had 60 years of experience; Dr. Henry B. Allen, who has practiced 56 years; Dr. Casey B. Graves, who has practiced 54 years; and Dr. Herbert B. Stewart, 53 years.

Dr. Parker to Come to Lexington.—Dr. Joseph B. Parker Jr., associate professor of psychiatry, Duke University Medical Center, Durham, N. C., has been named psychiatry department chairman for the University of Kentucky's new medical center in Lexington. He will be professor of psychiatry and will assume his new duties late next summer. Dr. Parker is chief of psychiatric service at the Veterans Administration Hospital, Durham, N. C. Associated with Duke University since 1953, he was a member of the University of Tennessee psychiatry faculty from 1949-53. His major research interest is in the field of manic-depressive reactions. Dr. Parker recently was elected a member of the American Psychopathological Association. He is a fellow of the American Psychiatric Association and the Southeastern Psychiatric Association. His professional activities include service as director of postgraduate refresher courses in neuropsychiatry for the Southeastern Area of the Veterans Administration.

MASSACHUSETTS

New Research Training Program.—A new training program for medical researchers has been announced jointly by officials of the New England Center Hospital and the Massachusetts Institute of Technology. A grant has been made by the National Heart Institute, National Institutes of Health, to the New England Center Hospital, which includes the Pratt Diagnostic Clinic, to establish a three-year training program in cooperation with M. I. T. for clinical scientists in cardiovascular and pulmonary research. The grant will be under the direction of Dr. Samuel Proger, physician-in-chief, New England Center Hospital, and professor of medicine, Tufts University School of Medicine. In direct supervision will be Dr. Leon Cander who heads the hospital's pulmonary physiology laboratories. The program was developed by Dr. Cander in conjunction with Irwin W. Sizer, Ph.D., chairman, department of biology at M. I. T. As planned, the program will provide for the trainees to spend the first year of study as special graduate students at M. I. T., taking courses in advanced mathematics, physical chemistry, instrumentation, and other subjects applicable to their expected field of investigation. Their second year will be spent in special medical postgraduate studies at the New England Center Hospital and will include special graduate courses at M. I. T. In the third and final year each trainee will be encouraged to involve himself in a field of special investigation interest, spending his time in the Ziskind Research Laboratories of the New England Center Hospital and at M. I. T. for additional appropriate courses. For information, write the New England Medical Center, 37 Bennet St., Boston 11.

Projects to Reduce Mental Hospital Admissions.—Two research projects to reduce the number of in-patient admissions to mental hospitals, involving the use of psychiatric home treatment and a study of alternatives to hospitalization for geriatric patients, are underway at the Boston University

School of Medicine and Boston State Hospital. Both programs are supported by grants from the U. S. Department of Health, Education, and Welfare, Public Health Service, National Institute of Mental Health, and are under the direction of Dr. Walter E. Barton, of Boston, associate professor of psychiatry and superintendent of the hospital. Two teams, each consisting of a doctor, a psychiatric social worker, and a psychiatric nurse, working on the home-care project, are working in the Dorchester area of Boston, a community with 100,000 inhabitants who belong, predominantly, to the middle and lower class groups with mixed ethnic and religious backgrounds. The doctors use psychotherapy as their primary tool, as they would if they were seeing the patient in their office or an out-patient clinic. The geriatric project is being done in two stages. The first involves extensive interviews of 75 geriatric patients admitted to the hospital, their families, friends, and associates, to get as complete a picture as possible of the needs of older people, where in their lives they failed to provide for these needs, and what can be done to maintain these people in their home surroundings. The second step will involve interpretation of data to see what types of community resources are needed to allow these people to remain in their home communities, instead of admitting them to mental hospitals.

MICHIGAN

Campaign for Atomic Research Project.—The University of Michigan has launched a campaign to raise 2 million dollars for its Memorial–Phoenix Project for atomic research. At a meeting of 104 state business and industrial leaders April 1, James C. Zeder, Chrysler Corporation vice-president and campaign committee chairman, said that funds raised to establish the project in 1948 as a memorial to the university's World War II dead are nearly exhausted. A total of 8 million dollars was contributed by university students, alumni, friends, and industrial groups to start the Phoenix Project. The money has been used to build a million-watt nuclear reactor and research facilities, to support 185 research projects, to buy equipment, to free scientists for full-time investigations, and to provide information about the atomic energy field. The Phoenix Project reportedly "is the largest independent atomic research program in the world. It operates the nation's most powerful college nuclear reactor, has brought about the country's largest enrollment in nuclear engineering and science at the U-M, and has sent people to help 20 other nations set up their own peaceful A-energy programs."

Hold Open House for New Buildings.—Exhibits and demonstrations, ranging from monkey morphine addicts to laboratory research on individual cells, were displayed Feb. 22 when the University of Michigan Medical Center, Ann Arbor, held community "open house" in the new 8½-million-dollar buildings of the Medical School and School of Nursing. Over 25 exhibits were manned by faculty members of the various departments to give visitors a firsthand picture of the training and research activities. The Medical Sciences Building opened last fall and houses the departments of biological chemistry, pathology, and pharmacology. Located at the northwest corner of the Medical Center, the structure is the fifth building occupied by the Medical School since its establishment 109 years ago. Biochemists displayed a research laboratory in full operation, and pathologists opened their tissue laboratory. In the pharmacology department, visitors saw some of the 250 Indian macaca monkeys which are used in studying narcotic addiction. At the School of Nursing demonstrations of modern nursing care were given. A cancer display, a newly developed germ-free laboratory, and an apparatus which charts the effect of different drugs on a living turtle heart were featured. The new home of the Medical School consists of three interconnecting buildings linked to the University Hospital by an enclosed bridge. It contains over 123,000 square feet of teaching, research, and office space, including the administrative quarters of the two schools. The first medical building was erected in 1850 on the east side of the main campus at a cost of $9,991. In 1903, West Medical opened at a cost of $137,000 and this was followed in 1936 by East Medical, built at a cost of $858,283. Future plans call for a 9-million-dollar addition to the new Medical Sciences Building. This will be joined to the west end of the new structure and will provide space for the departments of anatomy, physiology, and bacteriology which are located in East Medical.

MISSISSIPPI

Annual State Meeting in Biloxi.—The Mississippi State Medical Association will hold its 91st annual session at the Hotel Buena Vista, May 12-14, under the presidency of Dr. Guy T. Vise, Meridian. Six section meetings will be held and the surgery section will include a panel on "Technical Mishaps Occurring During Surgery: Recognition and Management," moderated by Dr. James D. Hardy, Jackson. Dr. Louis M. Orr, Orlando, Fla., President-Elect, American Medical Association, will participate in the program, which lists the following essayists: Drs. A. Frank Adair Jr., St. Paul, Minn.; Jack R. Anderson, John Perrigo Fox, Ralph V. Platou, and Lewis J. Rutledge, New Orleans; James H. Ferguson, Miami, Fla.; Benjamin R. Gendel, Atlanta, Ga.; Phil C. Schreier and Alva B. Weir Jr., Memphis, Tenn.; and Edward R. Woodward, Gainesville, Fla. Scientific and technical exhibits are planned. Activities include a golf tournament and skeet shoot, May 13. For information write Mr. R. B. Kennedy, 735 Riverside Dr., Jackson, Miss., Executive-Secretary.

MISSOURI

Student Gets Research Fellowship.—John R. Esther, who last June finished his second year in medicine at the University of Missouri School of Medicine, Columbia, has received a postsophomore fellowship in pathology from the National Institutes of Health, Bethesda, Md., to study ways to predict in the unborn child the severity of an infant disease caused by parental differences in the Rh factor. He is now working full time on his research in the department of pathology at the Medical Center, under the direction of Dr. Joseph E. Flynn, chairman, department of pathology, and Dr. Vincent P. Perna, assistant professor of pathology. Mr. Esther is recorded as the first student in the history of the School of Medicine to be awarded a postsophomore fellowship by the National Institutes of Health of the U. S. Public Health Service.

NEW JERSEY

Conference on Mental Retardation.—The second annual Spring Conference of the Training School of Vineland will be held May 11-12, on the subject "Practical Problems" of coordinating and integrating all services related to the treatment, training, and management of the mentally retarded. Sponsors of the conference are the Training School and the New Jersey Department of Institutions and Agencies. The conference was developed under a grant from the National Institute of Mental Health. The clinical areas of psychiatry, psychology, education, speech and hearing, medicine, social work, and daily care will be represented. The conference goal is to produce a set of written, specific, desirable practices of coordinating and integrating information which can be used by workers in schools, institutions, clinics, other agencies and private practice. The conference is composed of panels and subworkshops, with representatives from the seven clinical areas represented in each. Two lectures will be presented: "Diagnosis . . . Original and Continuing," by Dr. Margaret J. Giannini, administrative director, Mental Retardation Clinic, New York Medical College; and "Recommendations by Clinicians," by Dr. William P. Hurder, of Atlanta, Ga., assistant director for mental health, Southern Regional Education Board. For information write Walter Jacob, Ph.D., Director, The Training School, Vineland, N. J.

NEW YORK

Dr. Lotspeich to Come to Rochester.—Dr. William D. Lotspeich, chairman, physiology department, University of Cincinnati College of Medicine, since 1951, will come to the University of Rochester School of Medicine and Dentistry as chairman of its department of physiology. Dr. Lotspeich will begin his new duties at the Medical School July 1, succeeding Wallace O. Fenn, Ph.D., who has headed the department since 1924. Dr. Fenn is retiring from the chairmanship but will continue as professor of physiology. Dr. Lotspeich is also Joseph Eichberg Professor of Physiology. After serving as instructor and assistant professor in physiology at Syracuse University College of Medicine from 1947 to 1949, Dr. Lotspeich spent two years as a research fellow in biochemistry at Oxford University, England, where he worked on tissue metabolism with Sir Rudolph Peters. He is a member of the Physiological Study Section of the National Institutes of Health, U. S. Public Health Service, and of the Advisory Council, Life Insurance Medical Research Fund of New York.

New York City

City Hospital Restores Name.—New York City's new municipal hospital, known for a brief time as Elmhurst General Hospital, has had restored to it its former name of City Hospital. Founded in 1832, it has a bed capacity of 1,066 and serves as the municipal hospital for half the borough of Queens, which now comprises two million people.

Lecture on Radiation Therapy.—The Radiation Therapy Alumni Association of Bellevue Hospital announced that the eighth annual Ira I. Kaplan Lecture, "Megavoltage X-Ray Therapy," will be given by Dr. John W. Boland, director of radiotherapy, Mt. Sinai Hospital, on May 7, 5:30 p. m., at the New York University Bellevue Medical Center, 31st Street and First Avenue, Founders Hall.

Establish Annual Fried Lecture.—Patients of Dr. Boris M. Fried have established an annual lecture at New York Medical College in his honor to be known as the Dr. B. M. Fried Lecture. The first address was given March 13. Wendell J. Krieg, Ph.D., professor of anatomy, Northwestern University Medical School, Chicago, was the speaker. Dr. Fried, clinical associate in the department of medicine at New York Medical College, has served on the staff of the department of pathology, Harvard Medical School, and has done experimental pathology at the Peter Bent Brigham Hospital, Boston. Later he was a research fellow in pathology at Mount Sinai Hospital.

Dr. Loeb Receives Kober Medal.—Dr. Robert F. Loeb, professor of medicine, Columbia University, since 1938, has been awarded the Kober Medal for 1959. The medal is provided for by the Kober Foundation, established at Georgetown University, Washington, D. C., in 1923. Dr. Loeb was selected for this year's medal by the Association of American Physicians "in recognition of his contributions to the progress of the medical sciences." He will receive the award at the association's annual meeting in Atlantic City in May. Dr. Loeb, who holds honorary doctorate degrees from the Universities of Chicago, Paris, Strasbourg, and Wales, was Lambert

Professor of Medicine at Columbia from 1942 to 1947 and has been Bard Professor of Medicine there since 1947. The award of the Kober Medal is provided for by an endowment fund established in 1923 by Dr. George M. Kober to commemorate the 50th anniversary of his graduation in medicine from Georgetown. The fund also pays the expenses of an annual lecture on a medical subject, a scholarship in the Georgetown Medical School, and a gold medal "to be awarded to the best student in hygiene."

Exhibit of Books on Physicians.—On view at The New York Academy of Medicine is an exhibit entitled "Books About Physicians" devoted to literary contributions by physicians and about medical life. In the category devoted to the physician in fiction is a copy of Sinclair Lewis' "Arrowsmith," deposited in the Library by Paul De Kruif, Ph.D., who collaborated on the work. One exhibit case is devoted to Dr. Hans H. Zinsser, a native New Yorker, who for many years held the chair of bacteriology and immunology in the College of Physicians and Surgeons and was later appointed to a similar chair in the Harvard University Medical School, Boston. He was distinguished as a teacher, investigator, literary man, and poet. Three cases are devoted to physicians and medicine as portrayed in fiction and drama, from the works of Rabelais to Doctor Zhivago. There are medical essays of distinguished physicians, such as Maimonides of the 12th century and Oliver Wendell Holmes of the 19th. Medicine's modern poets Merrill Moore and William Carlos Williams are represented. A number of autobiographies by medical men are exhibited. Other cases hold narratives of medical missionaries and a wide variety of contributions shown in anthologies. The exhibit will be on display in the library through June 30.

PENNSYLVANIA

Industrial Scientists Honored.—Dr. Karl H. Beyer Jr. and James M. Sprague, Ph.D., of West Point, will receive the Merck Board of Directors' Scientific Award for scientific accomplishments. A means of honoring industrial scientists, the award takes the form of an appropriate scroll setting forth the scientist's achievements and a grant of funds by Merck to one or more educational institutions to support an appropriate educational activity in the scientist's name. The institution is chosen by the recipient and the type of educational activity is developed by the recipient and the university. In honor of Dr. Beyer, the Merck board is granting $25,000 to the University of Wisconsin to establish the Karl H. Beyer Jr. Visiting Professorship in the university's School of Medicine. Of the $25,000 appropriated in honor of Dr. Sprague, the board is granting $10,000 to Franklin College (Franklin, Ind.) to set up the James M. Sprague Science Award, to provide financial assistance to "exceptionally able" students in natural science. The sum of $15,000 is being granted to the University of Wisconsin to establish the James M. Sprague Fund to be used by the university's department of chemistry for a visiting lectureship in organic chemistry, the James M. Sprague Lectureship. The Directors' Scientific Award was established by the Merck Board in 1951 at the suggestion of former company president James J. Kerrigan. These awards now support the Karl Folkers Lecture Series in Chemistry at the Universities of Illinois and Wisconsin, the Lewis Hastings Sarett Scholarship in Chemistry at Northwestern and Princeton Universities, the Max Tishler Prize Scholarship at Tufts College, and the Max Tishler Lectures in Chemistry at Harvard University.

Philadelphia

Foreign Visitors.—The University of Pennsylvania School of Medicine's department of psychiatry was visited by five foreign psychiatrists at a special round-table conference on psychiatric education March 23. The visitors included Dr. Hans Hoff, chairman, department of psychiatry, University of Vienna; Dr. Pierre Deniker, senior lecturer, University of Paris; Dr. Roland Kuhn, professor of psychiatry, University of Zurich; Dr. Michael Shepherd, department of psychiatry, University of London; and Dr. Hanns Hippius, department of psychiatry, University of Berlin.

Personal.—Dr. Albert P. Seltzer has been appointed as senior attending otolaryngologist to the Albert Einstein Medical Center, Southern Division, Philadelphia.——Dr. Edward L. Bortz, formerly president of the American Medical Association, and now chief, medical service, the Lankenau Hospital, Philadelphia, was named chairman of the 1960 National Health Forum. The forum, an annual national conference, is sponsored by the National Health Council on behalf of its more than 60 member agencies.——Dr. C. Wilmer Wirts, associate professor of medicine, Jefferson Medical College, was awarded a scroll March 18 in recognition of his service rendered during his three-year term (1957-59) as director of the Postgraduate Institute of the Philadelphia County Medical Society.

Undergraduate Education Via Television.—An experiment linking five major medical schools by closed-circuit TV was held March 31-April 10. Joining in this network for undergraduate medical education were the University of Pennsylvania School of Medicine, Jefferson Medical College, Temple University School of Medicine, Hahnemann Medical College, and Woman's Medical College of Pennsylvania. The programs were produced by the Medical Education Service Unit of Smith Kline & French Laboratories, Philadelphia. The special telecasts, a series of five lectures by Dr. Joseph W. Spelman, medical examiner for the City of Philadelphia, reportedly marked the first time that five medical schools used the technique of television for joint lecture-demonstration purposes. About 1,300 students in selected classes of the schools watched the color telecasts on screens as large as 4½-by-6 feet in their own auditoriums. The series of 45-minute programs was arranged under the subject, "Forensic Medicine." A telephone hook-up was used to relay the students' questions directly to Dr. Spelman through a moderator at each of the schools. The idea for the lecture series grew out of talks between Dr. Charles S. Cameron, dean of Hahnemann Medical College, and officials at Smith Kline & French.

SOUTH CAROLINA

Annual Meeting in Columbia.—The South Carolina Medical Association will hold its annual meeting in Columbia, May 13-14. Two panel discussions are planned on (1) cancer, and (2) vascular disease, moderated by Dr. Harold R. Pratt-Thomas and Dr. Robert Wilson, Charleston, respectively. The following papers will be presented by out-of-state speakers:

Doctor Looks at the Problem of Radiation Hazards, Dr. Eugene P. Pendergrass, Philadelphia.
Advances in Cancer Control, Dr. John R. Heller, Bethesda, Md.
Fenestration Operation on Ear, Dr. J. Brown Farrior, Tampa, Fla.
Some Pediatric Orthopedic Problems, Dr. William T. Green, Boston.
Vesicoureteral Reflux in Children: Diagnosis and Management, Dr. Victor A. Politano, Durham, N. C.
Problems in Staphylococcus Infection, Dr. Walter A. Murray, Columbus, Ohio.

A Clinicopathologic conference is scheduled for the afternoon of May 14. Speaker at the annual banquet that evening will be Dr. Gunnar Gundersen, La Crosse, Wis., President, American Medical Association. For information write Mr. M. L. Meadors, 309 W. Evans St., Florence, S. C.

TENNESSEE

Society Elections.—The Tennessee State Orthopaedic Society held its 11th annual meeting at the University of Tennessee College of Medicine March 15. Dr. George W. Shelton was elected president; Dr. W. Houston Price, vice-president; Dr. Maurice A. Canon, secretary-treasurer. The 1960 meeting will be held in Chattanooga.——The following are officers of the Nashville Academy of Medicine for 1959: president, Dr. Rollin A. Daniel Jr., and secretary-treasurer, Dr. Douglas H. Riddell, 2318 W. End Ave., Nashville 5, Tenn.

Name Dr. Zilversmit Heart Investigator.—Donald Zilversmit, Ph.D., professor of physiology, University of Tennessee, Memphis, was named the seventh "Career Investigator" of the American Heart Association. Career investigators are "outstanding scientists" who receive support from the American Heart Association throughout their productive lives. In his studies Dutch-born Dr. Zilversmit has concentrated on the body's use of lipids. The investigatorship provides $30,000 annually to cover the investigator's salary and to help underwrite the expenses of his laboratory. Its purpose is to relieve leading investigators of financial and other pressures and permit them to work without interruption on problems of their own choosing.

Personal.—Dr. Frank L. Roberts, associate dean, University of Tennessee College of Medicine, Memphis, will go to Iran for two years as a consultant in medical education of the University of Shiraz, an English-speaking university in southern Iran under auspices of the International Cooperation Administration.——Thomas P. Nash Jr., Ph.D., professor of chemistry and dean of the School of Biological Sciences, University of Tennessee Medical Units, Memphis, has won the 1958 Southern Chemist Award of the American Chemical Society's Memphis Section. The gold medal, given annually "for distinguished service to the profession of chemistry in the Southern states," was presented to Dr. Nash at a banquet at the University of Florida Dec. 12.

Dr. Rogers Named Department Head.—Dr. David E. Rogers, associate professor of medicine and chief of the division of infectious disease, New York Hospital, Cornell Medical Center, was named professor of medicine and head of that department at Vanderbilt University School of Medicine, Nashville. Dr. Rogers, whose appointment will take effect at the beginning of the 1959-1960 academic year, succeeds Dr. Hugh J. Morgan, who retired last June. Since June the department has been directed by a committee, with Dr. Rudolph H. Kampmeier as chairman. Dr. Rogers was appointed assistant professor of medicine on the New York Hospital–Cornell faculty in 1954, spent the following year as visiting investigator at the Rockefeller Institute for Medical Research, was made chief of the division of infectious disease in 1955, and was promoted to associate professor in 1956.

UTAH

Dr. Scott M. Smith Honored.—Dr. Scott M. Smith, of Salt Lake City, received the citation of merit award from the University of Missouri Alumni Association April 7. The presentation was made at the Medical School Alumni lunchen in connection with the Missouri State Medical Association meeting. Dr. Smith, associate clinical professor, department of anesthesiology, University of Utah College of Medicine, was elected president of the American Board of Anesthesiology in 1958 and has been a board member since 1950. He was president of the American Society of Anesthesiologists in 1956, and became secretary of the American Academy of Anesthesiology in 1957. In the American Medical Association he was chairman of the section on anesthesiology in 1957 and for eight years was representative to scientific exhibits on anesthesiology.

VERMONT

Iranian Visitor.—Dr. Sh. Mofidi, professor, University of Teheran, Iran, was a visitor at the University of Vermont College of Medicine, Burlington, recently, observing the teaching of preventive medicine and discussing the problems of selecting and evaluating students for admission to medical school. Dr. Mofidi returned a visit to Iran made by Dean George A. Wolf Jr. last summer.

VIRGINIA

Dr. Paquin Comes to Charlottesville.—Dr. Albert J. Paquin Jr. was appointed professor of urology and chairman of the department of urology, University of Virginia School of Medicine, Charlottesville, effective May 1. Dr. Hugh Warren, associate professor of urology, has served as acting chairman of the department since the death of Dr. Samuel A. Vest Jr. last April. Dr. Paquin comes to the University of Virginia from Cornell University Medical College, New York City, where he was associate professor of clinical surgery and urology since July 1, 1957, and associate attending surgeon in urology at the New York Hospital-Cornell Medical Center. Dr. Paquin's interests have centered on the urological problems of childhood and the metabolic derangement induced by surgical trauma. He plans to continue this research.

Annual General Practice Meeting.—The ninth annual scientific assembly of the Virginia Academy of General Practice will be held May 7-10 at the Jefferson Hotel, Richmond. The morning of May 8 will be devoted to a program of the Virginia Diabetes Clinical Society and that afternoon the annual business meeting will be held. The following papers will be presented by out-of-state speakers:

Early Diagnosis of Uterine Cancer, Dr. C. Bernard Brack, Baltimore.

The Hirsute Female, Dr. Robert B. Greenblatt, Augusta, Ga.

Some Problems in Geriatric Medicine, Dr. Edward Henderson, Montclair, N. J.

The Child Handicapped by Nephrosis, Dr. Milton Rapoport, Philadelphia.

The Child Handicapped by Cerebral Palsy, Dr. George G. Deaver, New York City.

Man in Space, Capt. W. M. Snowden, Washington, D. C.

Therapeutically Induced Weight Gains in Hypertensives, Dr. Harold Feldman, Livingston, N. J.

Newer Concepts in the Treatment of Common Skin Diseases, Dr. Edmund F. Finnerty Jr., Boston.

Present Status of Adrenocortical Steroid Therapy, Dr. Nicholas E. Capeci, West Point, Pa.

Treatment of Hypertension, Dr. Francis L. Chamberlain, San Francisco.

Two motion pictures will be shown and exhibits are planned. Guest speaker at the annual banquet May 9, 7:30 p. m., will be Mr. T. Coleman Andrews, of Richmond, who will present "Wasteful Spending, Confiscatory Taxation and Inflation Are Not Laughing Matters." For information write the Virginia Academy of General Practice, 4205 Dover Road, Richmond 21, Va.

WASHINGTON

Appoint English Microbiologist as Laboratory Chief.—Dr. John C. Sherris, of Manchester, England, a member of the University of Manchester faculty, has been appointed chief of the Microbiology Laboratory of the University of Washington Teaching and Research Hospital, Seattle. Dr. Sherris, a graduate of Middlesex Hospital Medical School of London University, received his bachelor of medicine and bachelor of science degrees in 1948 and his doctor of medicine degree in 1950. He has been senior lecturer in bacteriology at the University of Manchester since 1956. Dr. Sherris' research has been in the application of experimental methods to problems in the diagnosis, treatment, and prevention of infectious disease in man.

WISCONSIN

Dr. Evans to Head New Department.—Dr. Alfred S. Evans, who for the past six years has been director of the Preventive Medicine Section of Student Health and associate professor of medical microbiology, University of Wisconsin Medical Center, Madison, has recently been appointed chairman of the newly established department of preventive medicine at the center and director of the State Laboratory of Hygiene. To develop a "broad and vigorous program" in preventive medicine and public health, the department has been completely divorced from the student health program and its educational and research activities merged with the program of the state Laboratory of Hygiene. However, the Laboratory of Hygiene shall continue to function as a separate unit—with Dr. Evans heading both departments. Dr. Evans has been associated with the University of Wisconsin Medical Center since 1952 and has held various positions on the staff of Yale University, New Haven, Conn. Dr. Evans will replace retiring Dr. William D. Stovall as director of the state Laboratory of Hygiene. Dr. Stovall, who headed the program for over 30 years, has agreed to stay on as acting director until Sept. 1 to allow Dr. Evans to study epidemiology and public health at the University of Michigan School of Public Health.

GENERAL

Travel Grants for Goiter Conference.—The fourth International Goiter Conference will be held July 5-9, 1960, in London, England, under the auspices of the London Thyroid Club and the American Goiter Association. The American Goiter Association plans to make available "to worthy candidates" a limited number of travel grants for participants of this meeting. Application blanks are available from Dr. John C. McClintock, 149½ Washington Ave., Albany 10, N. Y., U. S. A. Applications will be received until Jan. 1, 1960.

Dr. Smith Goes to Washington.—The Pharmaceutical Manufacturers Association named Dr. Austin Smith, former editor of THE JOURNAL as its first full-time salaried president following a year of presidency of George F. Smith, who served as the first president after the 1958 merger combining the American Drug Manufacturers Association and the American Pharmaceutical Manufacturers Association. Dr. Smith will be located at PMA's Washington headquarters. Since 1953 he has been executive editor of the *World Medical Journal* and since 1954 has served as chairman of the board of the U. S. Committee, World Medical Association.

Otoophthalmological Meeting in Las Vegas.—The Pacific Coast Oto-Ophthalmological Society's annual meeting will be held May 3-7 at the Hotel Riveria, Las Vegas, Nev. Guest speakers will include: Drs. Robert R. Newell, San Francisco; William P. Mikkelsen, Los Angeles; James F. Crow, Ph.D., Madison, Wis.; Stuart C. Cullen, San Francisco; George E. Shambaugh Jr., Chicago; Sidney Riegelman, Ph.D., San Francisco; Lawrence R. Boies, Minneapolis; Dean M. Lierle, Iowa City; A. Edward Maumenee, Baltimore; John W. Henderson, Rochester, Minn.; and Morton D. Leigh, Los Angeles. The social events committee has planned programing for the members and their wives during the meeting. The President's Reception and Buffet Supper will be held Sunday evening, May 3. For information write Dr. Homer E. Smith, 686 Twelfth Ave., Salt Lake City 3, Utah, Executive Secretary-Treasurer.

Annual Psychosomatic Meeting.—The American Psychosomatic Society's 16th annual meeting will be held at Chalfonte-Haddon Hall, Atlantic City, May 2-3. The program will consist of three general sessions, a portion of one of which will be set aside for Prof. P. K. Anokin, chief, department of neurophysiology, Academy of the Medical Sciences, U. S. S. R. His subject will be "On the Specific Character of the Activating Influence of the Reticular Formation on the Cerebral Cortex." A fourth session will be allotted to the panel presentation of "Problems of Specificity in Psychosomatic Disorders." This panel will deal with the report of the findings of the long-term study of the Chicago Institute for Psychoanalysis. The registration fee for nonmembers is $5. Students, interns, residents, and fellows will be admitted to the sessions upon payment of $1 and presentation of proper identification. For information, write the American Psychosomatic Society, 265 Nassau Road, Roosevelt, N. Y.

Current Poliomyelitis Morbidity Trends.—The Communicable Disease Center, Atlanta, Ga., reported that during the week ending March 28, there were 19 cases of poliomyelitis reported to the National Office of Vital Statistics, of which 15 were paralytic. The total for the preceding 6-week period was 136 cases, higher than the 84 cases during the comparable period in 1958, but lower than the 215 cases reported during this same interval in 1957. The only known concentration of cases in 1959 has been in Pike County, Mo. Since the last week in December, 15 cases of poliomyelitis were reported from Pike County, by Dr. Edgar A. Belden, director, Bureau of Communicable Disease Control, Missouri Division of Health. All cases were members of an Amish Mennonite Community of about 350 persons divided among 50 families. Of these 15 cases, 7 were paralytic and 8 nonparalytic. One fatality has been reported. The 34 cases reported from Florida, 22 paralytic, are distributed throughout the state, in a pattern following the population density.

Cardiology Meeting in Philadelphia.—The American College of Cardiology will hold its eighth annual convention at the Benjamin Franklin Hotel, Philadelphia, May 25-29, 1959. The program covers recent trends in medical and surgical progress in cardiology. Dr. John S. LaDue, New York City, is national chairman, program committee; Dr. Robert P. Glover, Philadelphia, is advisory chairman to the local committee in charge of convention arrangements; Dr. Seymour Fiske, New York City, is national chairman. Dr. Claude S. Beck, Cleveland, is moderator of a scientific session on surgical problems in coronary and valvular heart disease, featuring new techniques, use and abuse of pump oxygenators, pacemakers, and the evaluation of postoperative syndromes. Dr. Ashton Graybiel, Pensacola, Fla., has arranged a special session on the newer challenges in aviation medicine and the newer aspects of space cardiology. There will be scientific sessions devoted to phonocardiography, ballistocardiography, metabolism, and therapy. Fireside conferences will allow audience participation in discussion of clinical and research problems. For information write the Secretary, Dr. Philip Reichert, American College of Cardiology, Empire State Bldg., New York 1.

Northern Tri-State Meeting.—The 86th annual meeting of the Northern Tri-State Medical Association will be held at the Schuler Hotel, Marshall, Mich., May 7, under the presidency of Dr. James E. Bailey, Coldwater, Mich. The following papers are scheduled:

Open Reduction, Primary and Secondary Fusions in Fractures of the Os Calcis, Dr. Homer H. Stryker, Kalamazoo, Mich., and Dr. Harold J. Meier, Coldwater, Mich.
Diagnosis and Treatment of Peripheral Vascular Disease of the Lower Extremities, Dr. D. Emerick Szilagyi, Detroit.
Investigation and Treatment of Recurrent Urinary Calculus Disease, Dr. William C. Baum, Grand Rapids, Mich.
Commercial Insurance Looks at Blue Cross, R. L. Paddock, president, Time Insurance Company, Milwaukee, Wis.
Laboratory Aids in the Differential Diagnosis of Functional Gynecological Disorders, Gardner M. Riley, Ph.D., Ann Arbor, Mich.
Chemotherapy of Leukemia and Lymphoma, Dr. Frank H. Bethell, Ann Arbor, Mich.

At the luncheon meeting an address will be given by Rev. Calvin Didier, LaPorte, Ind., on "How Much Does The Spirit Weigh." A ladies' program is arranged. For information write Dr. Francis E. Elliott, Northern Tri-State Medical Association, 130 N. Fulton St., Wauseon, Ohio, Secretary-Treasurer.

Bacteriologists Meet in St. Louis.—The 59th general meeting of the Society of American Bacteriologists will be held May 10-14 at the Sheraton-Jefferson and Statler Hotels, St. Louis, with the Eastern Missouri Bacteriologists as hosts. P. R. Edwards, Communicable Disease Center, Chamblee, Ga., president of the society, will open the meeting. The ONR Lecture, "The Three Faces of Immunology," will be given by Ashley A. Miles, of the Lister Institute of Preventive Medicine, London, England. Over 400 papers are scheduled for presentation under four division headings. The following five symposiums are arranged: "Steroid Metabolism," "Biology of Cells Modified by Viruses or Antigens," "Infectious Agents and Phagocytic Cells," "Initiation of Bacterial Growth," and "Microbial Genetics." A. A. Newton, department of pathology, University of Cambridge, England, will give "Infection of Synchronously Dividing HeLa Cells by Herpes Simplex Virus," and "Antimicrobial Properties of Progesterone Analogues" will be given by C. Casas-Campillo, with Dora Balandrano and A. Galarza, Research Laboratories, Syntex, S. A., Mexico, as co-authors. Scientific motion pictures and commercial and scientific exhibits are planned. A program of ladies' activities and tours are arranged. For information write Mr. Samuel G. MacFarlane, 428 E. Preston St., Baltimore 2, Business Manager.

Mental Health Study in South.—A state-by-state study of mental health research in the Southern region has been launched by the mental health program of the Southern Regional Education Board, according to Dr. William P. Hurder, director of the program. The study is designed to get detailed information about the Southern region's resources and needs in mental health and behavioral science research, including research in mental retardation. It will provide an estimate of research projects in progress and how they are being carried out. Over 2,000 questionnaires have been distributed to research personnel and their administrators throughout the region with the cooperation of a committee of research survey chairmen appointed by the governor of each participating state. The cooperation of the Bio-Sciences Information Exchange and the Council of State Governments will supplement the study findings and broaden the scope of the data gathered. The regional mental health program was established in 1954 by the SREB at the request of the Southern Governors' Conference and is supported by an appropriation of $8,000 from each participating state. Its purpose is to aid states and Southern colleges and universities to train more qualified personnel for mental health programs and to aid in securing added support for needed research programs.

Establish Medical Council for Kansas City.—The Medical Council of the Metropolitan Area of Greater Kansas City was formally established at an organizational meeting March 16 in Kansas City. The members are the Clay County (Mo.) Medical Society, Jackson County (Mo.) Medical Society, Johnson County (Kan.) Medical Society, and Wyandotte County (Kan.) Medical Society. The immediate past-president, the president, and the president-elect or vice-president are designated as representatives of the society. The secretaries also attend meetings of the representatives in an ex officio capacity. The Medical Council, following a pattern established in the Washington, D. C. Metropolitan Area and also by the First District Branch of the Medical Society of the State of New York, has the purpose "to unify and give effect to the policies and purposes of the organized medical profession of Greater Kansas City to serve, sustain and promote the public health and welfare in matters involving the Metropolitan Area of Greater Kansas City; to promote programs designed to enhance the health and welfare of the people; and to fulfill on an area level, the established common purposes of the several county medical societies of this Council with due regard to the autonomy and authority of each county medical society." Membership is open to the county medical societies in the Metropolitan Area that may desire to participate. Dr. Dillard M. Eubank, of Kansas City, Mo., was selected chairman.

Establish Fellowship for Physician from India.—The creation of the Merck Sharp & Dohme International Fellowship in Rehabilitation for a physician from India to undertake advanced training in the United States has been announced. The fellowship will provide a minimum of one year of training in physical medicine and rehabilitation. Initial screening of applications will be done by a committee of Indian leaders in health and medical education. The international fellowship was made possible by a contribution of $10,000 to the World Rehabilitation Fund by the Merck Company Foundation on the recommendation of Merck Sharp & Dohme International Division, Merck & Co., Inc. The fellowship will be administered by the World Rehabilitation Fund, an American voluntary organization, in cooperation with the International Society for the Welfare of Cripples. The latter's affiliate in India is the Indian Society for the Rehabilitation of Crippled Children, of which Dr. Mrs. Gulbanoo Premji, Haji Ali Park, Clerk Road, Mahaluxmi, Bombay, is the national secretary. The World Rehabilitation Fund is a nonprofit organization supported by American industry, foundations, and individuals to assist in the international development of rehabilitation services for the physically handicapped. Currently there are 71 trainees (57 physicians and 14 nonphysicians) from 35 different nations who receive long-term advanced training in the United States under the auspices of the fund. Its honorary chairmen include Mr. Herbert Hoover, Mr. Harry S. Truman, and Mr. Bernard M. Baruch.

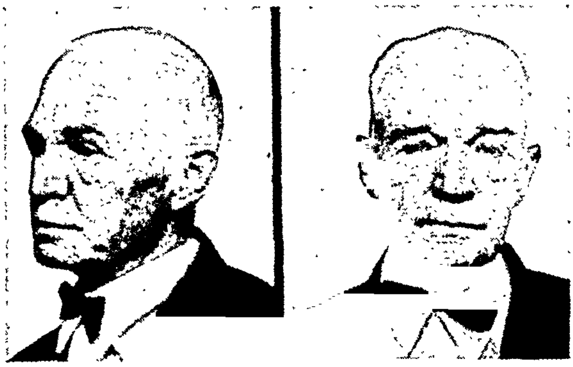
Tornadoes Take Fewer Lives.—The Statistical Bulletin of the Metropolitan Life Insurance Company has stated that the death toll from tornadoes in the United States was lower in the past five years than in any comparable period since the Weather Bureau began to keep systematic records of such storms more than 40 years ago. In the period 1954-1958 tornadoes took about 500 lives, half the loss sustained in each of the preceding five-year periods and little more than one-fourth the toll in 1924-1928. The reduced death toll in recent years reportedly has been due in part to improved tornado detection and warning services. The recent decrease in fatalities has been especially marked in the Southwest. There were 117 tornado deaths in the West South Central region during 1954-1958, compared with 444 five years earlier and with 507 in 1944-1948. Arkansas had only seven tornado deaths in the past five years, a small fraction of the losses suffered in the periods immediately preceding. Texas likewise experienced unusually small numbers of fatalities in recent years. Only three states—all of them in the Midwest—recorded an increasing number of tornado deaths in the period under review. Kansas, which had only five fatalities in 1944-1948 and 11 in the next five years, had 106 deaths in 1954-1958, a greater loss than that experienced by any other state in this period. Wisconsin suffered 37 fatalities in the recent five-year period while Missouri recorded 59 such deaths. The tornado which struck St. Louis early in February of the current year took 21 lives.

Foreign Speakers at Section Centennials.—Seven sections of the Scientific Assembly of the American Medical Association are celebrating their centennials in Atlantic City. Among the centennial participants will be several foreign speakers. R. R. A. Coombs, Ph.D., professor of pathology, University of Cambridge, England, will be the guest centennial speaker for the Section on Pathology and Physiology June 11, in the ballroom of the Shelburne Hotel. His subject will be: "Demonstration of Antigens on Tissue Cells by the Mixed Agglutination Reactions." Mr. Andrew M. Claye, president, Royal College of Obstetricians and Gynecologists, Leeds, England, will be the speaker at a commemorative luncheon in celebration of the 100th anniversary of the founding of the Section on Obstetrics and Gynecology, June 10, in the ballroom of the Sheraton–Ritz Hotel. On June 12, Dr. Coombs and Mr. Claye will be participants in a panel discussion on erythroblastosis fetalis in a joint meeting of the Section on Obstetrics and Gynecology and the Section on Pathology and Physiology, commemorating the 100th anniversary of both sections. This will take place in Trimble Hall, Claridge Hotel. Dr. Jeremy N. Morris, London Hospital Research Laboratories, Ashfield Street, London, will be the guest centennial speaker at the joint meeting of the Section on Experimental Medicine and Therapeutics and the Section on Internal Medicine, which is scheduled for Thursday afternoon in the ballroom of Cenvention Hall. He will take part in a symposium on "Basic Problems of Coronary Disease Today" and will speak on "Occupation and Heart Disease."

Study of Hospital Admissions.—The National Opinion Research Center of the University of Chicago has embarked on a two and one-half year study of hospital admissions. The Health Information Foundation granted $200,000 to the center to investigate the full range of reasons for admitting patients. Chauncy D. Harris, Dean of the Division of Social Sciences of the university and a trustee of the center, announced the grant and said that a systematic study would be made on the medical, social, personal, and professional reasons behind a stay in the hospital. "The aim of this investigation is to develop a better understanding of the role of the hospital and the demands upon it by the community." Of special interest and study will be the bearing of hospital insurance coverage on decisions to hospitalize or not to hospitalize when other factors affecting the decision are controlled, Harris said. Mr. Clyde W. Hart, director of the National Opinion Research Center, said that hospital admissions throughout the nation exceed 20 million annually. He said that the study for the Health Information Foundation will be based on a sample of admissions to hospitals in the state of Massachusetts. Cooperating will be the Massachusetts Medical Society, the Massachusetts Hospital Association and the Blue Cross-Blue Shield plans in the state. The Health Information Foundation was organized in 1950 as a contribution by the drug, pharmaceutical, chemical, and allied industries to research and education in the social and economic aspects of medical care. The National Opinion Research Center is a specialized research agency affiliated with the University of Chicago. It undertakes specific projects in gaining information on social and scientific problems and collects original data for its reports.

Conference on Legal Environment of Medical Science.—The National Society for Medical Research in conjunction with the University of Chicago has called the first National Conference on the Legal Environment of Medical Science, "to bring order into . . . the laws and regulations governing medical research." The meeting will be held May 27-28 on the University of Chicago campus. Practical problems such as access to cadavers and obtaining animals for humane use in laboratories has stimulated the society, whose membership includes all the accredited medical schools and most medical research associations, to issue a call for clarification of standards. Participants will include scientists, legal scholars, religious leaders, and representatives of various groups affected by differing practice, decisions, and laws. The conference will focus on three major fields: medical experiments on human subjects; medical studies involving the use of dead human bodies; and medical experiments on animal subjects. The conference will attempt to reach agreements on ethical standards for the experimental use of human volunteers, cadavers, and laboratory animals. The conferees will seek to develop principles for a model legal code to govern research in medicine. Rev. Thomas J. O'Donnell, S. J., regent, Georgetown University School of Medicine, will be chairman of the section on human experimentation. Russell T. Woodburne, Ph.D., professor of anatomy, University of Michigan School of Medicine, Ann Arbor, will be the chairman of the section on the use of cadavers. William T. S. Thorp, D.V.M., dean, College of Veterinary Medicine, University of Minnesota, Minneapolis, will be the chairman of the section on animal experimentation. Irvin Ladimer will serve as conference secretary. Inquiries should be addressed to the National Society for Medical Research, 920 S. Michigan Ave., Chicago 5.

Wanted by the FBI.—William Milton Hoffman, who may seek treatment for a stomach ailment and is known to have had tuberculosis, is being sought by the FBI for unlawful flight to avoid confinement for armed robbery. On Feb. 11, 1949, Hoffman was apprehended at Surfside, Fla., and was returned to Michigan, where he was sentenced to serve 10 to 20 years in the State Prison at Jackson. He escaped confinement Oct. 11, 1952. Hoffman has been convicted for burglary, larceny, and armed robbery. He should be considered dangerous. A federal complaint was filed at Detroit in 1956, charging Hoffman with violation of the unlawful Flight to Avoid Confinement Statute. He was born in 1895 in Carter County, Ky.; height 5 ft. 8 in.; weight 128 lbs.; gray hair; blue eyes; medium complexion; race, white; occupation, plumber, telegraph operator. He has ¾-in. scar on back of head; cut scar in left eyebrow; moles below left eye; above right eye; and on right side of chin; ⅝ in. oblique scar below left wrist; two scars on second joint of left thumb; 1 in. oblique scar on palm of right hand near wrist. Hoffman is said to be a gambler, particularly on horse races. He has used these aliases: William Halliday; William Jennings Hoffman; Edward Holliday; William Huffman; William Marvin; William Murry; Raymond O'Brien; John Russell; Frank Webber; Frank Williams, and others. Anyone able to assist in locating this fugitive is requested to notify the Director of the Federal Bureau of Investigation, U. S. Department of Justice, Washington 25, D. C., or the Special Agent in Charge of the nearest FBI Division, the telephone number of which may be found on the first page of local telephone directories.



William Milton Hoffman

Award in Laryngology and Rhinology.—The American Laryngological Association announced that a sufficient fund has accrued from the Casselberry Fund "for encouraging advancement in the art and science of laryngology and rhinology," and that this sum is now available in part or as a whole, for a prize award. Theses must be in the hands of the Secretary of the American Laryngological Association, Dr. James H. Maxwell, Out-Patient Building, University Hospital, Ann Arbor, Mich., by Jan. 1. The Casselberry Award is a prize of money with accompanying certificate. The sum of money will be agreed upon by the council of the association after the manuscript has been evaluated by the Award Committee. It may be awarded in whole or in part among several contestants. Eligible contestants may be: (1) hospital interns, residents, or graduate students in rhinology and laryngology; (2) an individual with an M.D. degree actively practicing or teaching rhinology and laryngology in the Americas; (3) any scientific worker in rhinology and laryngology. Manuscripts shall be presented under nom de plume which shall in no way indicate the author's identity. There shall also be a sealed envelope bearing the nom de plume and containing a card showing the name and address of the contestant which the secretary shall keep. Manuscripts must be limited to 5,000 words and must be typewritten, double spaced on one side of the sheet. *The thesis shall not have been published elsewhere.* The successful thesis shall become the property of the association but this provision shall in no way interfere with publication of the thesis in the journal of the author's choice. Unsuccessful contributions will be returned promptly. The award, to be made at the annual meeting of the American Laryngological Association, shall be based on: originality of material; scientific and clinical value; suitability for this award; method of presentation as to style, illustrations, and references. The maximum amount shall not exceed $200.

FOREIGN

Plan Rehabilitation Center in Philippines.—What is reportedly the first community rehabilitation center in the Far East is to be developed in San Pablo, the Philippines, the Republic of the Philippines Ambassador to the United States, Carlos P. Romulo, announced in a press conference held at the Institute of Physical Medicine and Rehabilitation, New York City. Also participating in the press conference were Mr. George Hampton, senior executive vice-president, whose company, General Foods Corporation, granted the funds for the project, and Dr. Howard A. Rusk, president, World Rehabilitation Fund, and director, Institute of Physical Medicine and Rehabilitation. The San Pablo Rehabilitation Center is an out-patient rehabilitation center. It will provide medical, physical therapy, social work, prosthetics, bracemaking, and related rehabilitation services to the community of San Pablo. In addition to a medical director, the center will have a full-time staff of nine persons initially. Dr. Rusk explained that although there are a number of governmental or university-operated rehabilitation centers in the Far East including that of the National Orthopedic Hospital in Manila, the San Pablo Rehabilitation Center is the first to be community-sponsored and community-operated. Six physicians from the Philippines have returned to the Philippines within the past three years after receiving long-term postgraduate training in physical medicine and rehabilitation within the Department of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, and six additional physicians and a social worker from the Philippines are currently enrolled in such advanced training.

CORRECTIONS

Committee on Hypnosis.—The item in the Organization Section entitled "New Committee on Hypnosis" (March 21, page 1339) inadvertently omitted the fact that Dr. M. Ralph Kaufman of New York a member of the Council on Mental Health of the American Medical Association was appointed by the Chairman of the Council, Dr. Leo H. Bartemeier, as liaison member to the Council's new Committee.

Unlawful Practice.—The foreign letter from Canada entitled "Unlawful Practice Charge" (March 14 issue of THE JOURNAL, page 1225) states "For this purpose it was not required that he be licensed in the province (a step which would have involved an internship and examination)." This clause in parentheses is not true. An English physician who has been engaged by the Canadian Department of Indian Affairs to treat Indians, being a graduate of a British university and having his name on the General Register of the General Medical Council of the United Kingdom, would not have to do further internship before he could be licensed in this province. He simply has to furnish the College of Physicians and Surgeons of Ontario with certain information and/or documents, pay a small fee, and then write the Medical Council of Canada examinations.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing application is June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

ALASKA:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

ARKANSAS:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

CALIFORNIA: *Written.* San Francisco, June 15-18; Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral.* San Francisco, June 13; Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* San Francisco, June 14; Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

DELAWARE: *Examination.* Dover, July 14-16. *Endorsement.* Dover, July 23. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

DISTRICT OF COLUMBIA:* *Written.* Washington, June 8-9. Final date for filing application is May 1. Sec., Dr. Daniel Leo Finucane, 1740 Massachusetts Ave., N. W., Washington.

FLORIDA:* *Examination.* Miami Beach, June 21-23. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

GEORGIA: *Examination and Reciprocity.* Atlanta, June 10-11. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

GUAM: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

HAWAII: *Written.* Honolulu, July 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

IDAHO: *Examination and Endorsement.* Boise, July 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

INDIANA: *Examination.* Indianapolis, June 17-19. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

IOWA:* *Examination.* Iowa City, June 15-17. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

KANSAS:* *Examination and Endorsement.* Kansas City, June. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

KENTUCKY: *Examination.* Louisville, June 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

LOUISIANA: *Examination and Reciprocity.* New Orleans, June 4-6. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans.

MARYLAND: *Examination.* Baltimore, June 23-26. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

MICHIGAN:* *Examination.* Ann Arbor and Detroit, June 8-10. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

MISSISSIPPI: *Examination and Reciprocity.* Jackson, June 22-24. Sec., Dr. A. L. Gray, Old Capitol, Jackson 13.

MISSOURI: *Examination.* St. Louis, May 29-30. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

NEBRASKA:* *Examination.* Omaha, June 15-17. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

NEW HAMPSHIRE: *Examination and Reciprocity.* Concord, Sept. 9-12. Sec., Dr. Edward W. Colby, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, June 16-19. Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton 8.

NEW MEXICO:* *Examination and Reciprocity.* Sante Fe, May *18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave.,* Santa Fe.

NEW YORK: *Examination.* New York, Rochester, Syracuse, Buffalo and Albany, June 23-26. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

NORTH CAROLINA: *Written. Examination and Endorsement.* Raleigh, June 15-18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

NORTH DAKOTA: *Examination and Reciprocity.* Grand Forks, July 8-11. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

OHIO: *Examination.* Columbus, June 18-20. Sec., Dr. H. M. Platter, 21 West Broad St., Columbus 15.

OKLAHOMA:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

PENNSYLVANIA: *Examination and Endorsement.* Philadelphia and Pittsburgh, July 1-3. Sec., Mrs. Margaret G. Steiner, Box 911 Harrisburg.

PUERTO RICO: *Examination.* San Juan, Sept. 8. Sec., Dr. Joaquin Mercado Cruz, Box 9156, Santurce.

SOUTH CAROLINA: *Reciprocity.* Columbia, May 12; *Examination.* Columbia, June 23-24. Sec., Dr. H. E. Jervey, Jr., 1829 Blanding St., Columbia.

SOUTH DAKOTA:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

TEXAS:* *Examination and Reciprocity.* Fort Worth, June 22-24. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

UTAH: *Examination and Reciprocity.* Salt Lake City, July 810. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

VIRGINIA: *Examination.* Richmond, June 18-20. *Endorsement.* Richmond, June 17. Address: Board of Medical Examiners, 631 First St., S. W., Roanoke.

VIRGIN ISLANDS: *Examination.* Charlotte Amalie, St. Thomas, June 10. Chairman, Dr. Melvin H. Evans, Christiansted, St. Croix.

WASHINGTON:* *Examination.* Seattle, July 13-15. Administrator, Mr. Thomas A. Carter, Capitol Bldg., Olympia.

WEST VIRGINIA: *Examination.* Charleston, June. Sec., Dr. Newman H. Syer, State Office Bldg., No. 3, Charleston 5.

WISCONSIN:* *Written.* Milwaukee, July 14-16. *Reciprocity. Milwaukee, July 15. Sec., Dr. Thomas W. Tormey, Jr.,* 1140 State Office Bldg., Madison.

WYOMING: *Examination and Reciprocity.* Cheyenne, June 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARKANSAS: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

COLORADO: *Examination.* Denver, May 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

CONNECTICUT: *Examination.* New Haven, June 6. Exec. Asst. Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

DISTRICT OF COLUMBIA: *Examination.* Washington, May 18-19. Address: Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N. W., Washington.

FLORIDA: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

KANSAS: *Examination.* Kansas City, June 2-3. Sec., Dr. L. C. Heckert, Pittsburg.

MICHIGAN: *Examination.* Ann Arbor and Detroit, May 8-9. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

NEBRASKA: *Examination.* Omaha, May 5-6. Director, Mr. R. K. Kirkman, Bureau of Examining Boards, 1009 State Capitol Bldg., Lincoln.

SOUTH DAKOTA: *Examination. Vermillion, June 5-6. Sec.,* Dr. Gregg M. Evans, 310 East 15th St., Yankton.

WASHINGTON: *Examination.* Seattle, July 8-9. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

WISCONSIN: *Examination.* Milwaukee, June 6. Madison, Sept. 11. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

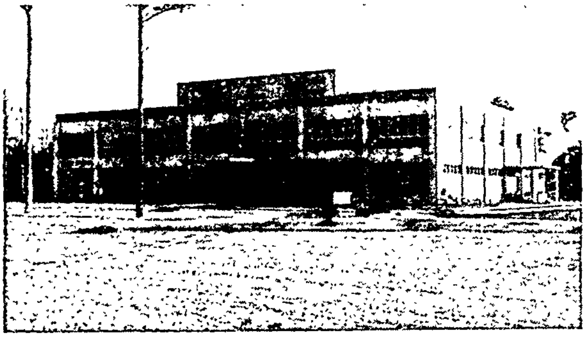
*Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Medical Officers Honored.—Col. Herbert W. Coone, U. S. A. F. (MC), was presented the Air Force Commendation Medal for meritorious service as Chief of Professional Services and Deputy Commander of the U. S. A. F. Hospital at Wiesbaden, Germany, from February, 1956, to December, 1958. During this period, the hospital underwent an unprecedented growth in workload and stature as the principal medical and surgical center for the United States Air Force in Europe. Doctor Coone was cited for his leadership and perseverance in improving the medical standards and for his conscientious research of preventive medicine and the community health program which resulted in an unprecedentedly low noneffective rate. Col. Ralph M. Lechausse, U. S. A. F. (MC), was presented the Legion of Merit for his meritorious performance of duty as Surgeon of Joint Task Force 7 during the 1958 nuclear tests in the Pacific. He was cited for his thorough investigation of possible exposure hazards to radiation resulting from nuclear tests and for creating and maintaining excellent international relationships in conducting such investigations.

New U. S. A. F. Hospital.—The new 50-bed U. S. A. F. Hospital at Myrtle Beach Air Force Base, S. C., was opened on March 1. This two-story, air-conditioned hospital offers outpatient service, including clinics in internal medicine, obstetrics, and surgery. Medical, surgical, and obstetrical facilities for inpatient care are located on the second floor. Col. Paul E. Lance, M. S. C., U. S. A. F., is commander of the hospital.



VETERANS ADMINISTRATION

Dr. Barnwell Honored.—The Veterans Administration's top award, the Exceptional Service award, was presented to Dr. John B. Barnwell, the agency's chief of medical research and education. Dr. Barnwell was cited for his part in organization of the VA-Armed Forces cooperative study of the chemotherapy of tuberculosis and for his leadership as VA assistant chief medical director for research and education. The VA-Armed Forces study, begun under Dr. Barnwell when he was chief of the VA tuberculosis service in 1946 and still continuing under that service, has played a large part in giving medicine modern drug treatments for tuberculosis.

Personal.—Dr. John M. Rumball, chief of medical service at the Veterans Administration hospital in Coral Gables, Fla., was appointed director of medical service for the agency in Washington, D. C., effective early in April. He also has accepted an appointment as clinical associate professor of medicine at Georgetown University School of Medicine in Washington, D. C.

FOOD AND DRUG ADMINISTRATION

Kelp Won't Help Your Diet.—Promoters of worthless products falsely represented as sources of additional vitamins and minerals in the diet and cures for disease continue to cheat the consumer and endanger his health. Each year, such promoters take from the American people large sums of money that could better be spent for wholesome, nutritious foods or competent medical advice. The Food and Drug Administration announced the seizure of 23,000 tablets of a so-called dietary supplement made with alfalfa, kelp, and brewer's yeast. The promoter claimed the tablets contained significant amounts of 14 vitamins, 10 minerals, and 14 proteins. His label carried an impressive-looking list of the amounts as measured in U. S. P. units. Agency analysts found the tablets did not contain amounts of vitamins, minerals, or proteins that could be measured in U. S. P. units. Kelp, one of the ingredients, is a source of iodine, which is already supplied in the diet. Alfalfa is a livestock feed. Brewer's yeast is used to make beer. Such ingredients do not prevent illness or generate health as claimed.

Pure Food Violations.—Tomato products and bulk wheat and rice continued to make up the largest volume of unfit foods removed from the market in February; 40 shipments totaling 886 tons of contaminated foods were seized. Of this amount, 293 tons of canned tomatoes in a single shipment were contaminated with fly eggs and maggots. More than 38 tons of other tomato products, including paste, puree, pizza sauce, catsup, and soup, contained spoiled tomatoes or fly eggs and maggots.

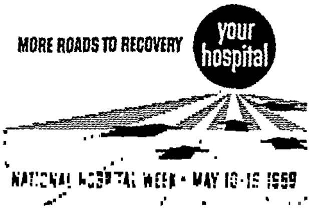
Two hundred ninety-six tons of wheat and rice were contaminated with rodent pellets, urine, hairs, and insect parts; 166 of the 179 tons of unfit warehoused foods was in rodent-contaminated chick peas (140 tons) and moldy, wormy, insect-damaged green coffee beans (26 tons) seized together in a New York warehouse.

An additional 58 tons of foods and 20,100 vitamin capsules were seized because of hazards to health. Included were 52 tons of mercury-contaminated wheat and 6 tons of an oil feed ingredient in which mineral oil had been substituted for edible oil. The vitamin product was deficient in vitamin B_1. Another 7 tons of foods seized as economic cheats included an instant chocolate flavored mix that was misbranded by false and misleading claims, an olive oil product in which teaseed oil was substituted for olive oil, and black pepper in which ground buckwheat hulls were substituted for black pepper. Of 10 drugs and devices seized in February, 3 were alleged to be misbranded by false and misleading claims. A medicated chest plaster was sold directly to parents as a four-day treatment for children's whooping cough, croup, spasmodic asthma, and hoarseness due to colds. Capsules of two prescription drugs—an amphetamine and a barbiturate—were substandard in rate of disintegration and drug content.

Truckdrivers Sentenced in Rotten Egg Racket.—Activities of the rotten egg combine continued in February despite numerous seizures and the threat of prison sentences hanging over key operators who are on probation. Egg shipments valued at $15,000 were seized at Eastern Seaboard cities from New York to Florida. On June 6 and 7, 1957, Food and Drug inspectors and state police followed a truckload of rotten eggs from central Maine, across New Hampshire, Massachusetts, and New York, and into New Jersey. For identification the inspectors had marked the eggs with an invisible crayon, which can only be seen under ultraviolet light. The driver reached speeds of 90 to 100 miles an hour during the 500-mile pursuit. Reaching Newark, N. J., ahead of his pursuers, he abandoned the truck and its cargo in a parking lot. Inspectors and U. S. Deputy Marshals maintained surveillance over the truck for five days before the marshal was able to serve seizure papers. The driver pleaded guilty to charges of interstate transportation of these eggs on Oct. 7, 1958. A day or two later he was reported to have made another pickup of rotten eggs at New England hatcheries. A week later he was apprehended in Vermont with a load of rotten eggs. At his sentencing, the court pointedly asked him if his family still ate eggs. On Feb. 13, 1959, the federal court at Newark, N. J., fined him $500 and placed him on probation for five years.

Pharmacists Convicted for Unauthorized Drug Refills.—A pharmacist-owner in Livingston, N. J., and a pharmacist-employee were convicted for unauthorized refilling of prescriptions for barbiturates and amphetamine. They dispensed up to four refills on the same prescription, voluntarily offering to double and triple the physician's recommended dosage and furnishing the increased amounts in subsequent refills. In one instance, a bottle of 100 capsules was sold as a refill of a prescription calling for only 12. The amount of money saved by purchasing drugs in large quantities was pointed out to Food and Drug inspectors, posing as customers. Federal Judge Thomas F. Meany (Newark, N. J.) said the temptation for extra profit in this case created a dangerous situation which could have fatal consequences. The court fined the owner a total of $3,000 on four counts and the employee $300 on one count.

Voluntary Corrective Actions.—Food manufacturers and warehousemen voluntarily spent a total of $96,985 during February in plant improvements suggested by agency inspectors to assure production of clean, wholesome products. A Pennsylvania baker eliminated possible insect contamination of his product at a cost of $35,000. He revamped his equipment for easy cleaning, stepped up his schedule of spraying for insects, and arranged to get regular advice on sanitation problems. A California olive oil producer spent $11,590 to correct insanitary practices in handling olives. A steam boiler, hopper, shaker screen and washing set-up, stainless steel holding tank, and special filter were among new items of equipment that he installed to process his raw materials more rapidly and keep them clean and unspoiled. Food firms voluntarily destroyed or converted to nonfood use more than 973 tons of unfit foods. Drug plants and warehouses voluntarily destroyed old and substandard drugs valued at $47,826.



DEATHS

Albright, George Carter Ⓜ Iowa City, Iowa; born in Pleasant Grove, Iowa in 1881; State University of Iowa College of Medicine, Iowa City, 1914; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served as vice-president of the Iowa State Medical Society; for 10 years president of the Johnson County Tuberculosis Association; in 1956 recipient of a medallion awarded by the Iowa Tuberculosis Association for his long and outstanding service to the group; past-president of the board of education; associated with the Mercy Hospital and the University Hospital, where he died Feb. 1, aged 77.

Alling, Marshall Louis Ⓜ Lowell, Mass.; Dartmouth Medical School, Hanover, N. H., 1909; fellow of the American College of Surgeons; veteran of World War I; served as medical examiner for the Middlesex North District; associated with St. Joseph's and Lowell General hospitals, and St. John's Hospital, where he died Feb. 8, aged 74.

Alspach, Walter Louis Ⓜ Miami, Fla.; University of Buffalo School of Medicine, 1918; associated with Mercy and Jackson Memorial hospitals; died Feb. 11, aged 64.

Ames, Sheppard Kellam Ⓜ Cape Charles, Va.; University of Virginia Department of Medicine, Charlottesville, 1925; interned at St. Joseph's Hospital in Baltimore; served overseas during World War I; member of the staff and board of trustees of the Northampton–Accomack Memorial Hospital in Nassawadox; died Jan. 30, aged 63.

Ausbrooks, Munch Trousdale, Smartt, Tenn.; University of Tennessee Medical Department, Nashville, 1895; postmaster; died in McMinnville Jan. 30, aged 88.

Baer, Raymond Bernhard Ⓜ Detroit; University of Chicago, The School of Medicine, 1931; specialist certified by the American Board of Obstetrics and Gynecology; veteran of World War I; clinical instructor in obstetrics and gynecology at Wayne University College of Medicine; associated with Receiving Hospital, St. Mary's Hospital, and Jennings Memorial Hospital, where he died Feb. 7, aged 59.

Barone, Samuel Ⓜ Buffalo, N. Y.; University of Buffalo School of Medicine, 1916; veteran of World War I; member of the American Academy of General Practice; on the staffs of the Deaconess and Lafayette General hospitals; died in the Millard Fillmore Hospital Jan. 29, aged 68.

Blount, Dillon Jefferson Jr. Ⓜ Mandeville, La.; University of Arkansas School of Medicine, Little Rock, 1946; member of the American Psychiatric Association; interned at the Charity Hospital of Louisiana in New Orleans; served a residency at the Veterans Administration Hospital in New Orleans; from 1946 to 1949 an officer in the medical reserve corps of the U. S. Army; formerly on the staff of the East Louisiana Hospital in Jackson; served on the staff of the Veterans Administration Hospital in Murfreesboro, Tenn.; superintendent of the Southeast Louisiana Hospital; died Jan. 28, aged 36.

Bolduc, Valmore Elmer, Nashua, N. H.; University of Vermont College of Medicine, Burlington, 1921; veteran of World War I; served as school physician; formerly city physician; on the staffs of St. Joseph's and Nashua Memorial hospitals; died Jan. 31, aged 61.

Bonar, Ethel Casto, Chicago; Western Reserve University School of Medicine, Cleveland, 1927; died Nov. 26, aged 65.

Boone, James Lunsford Ⓜ Green Cove Springs, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; specialist certified by the American Board of Otolaryngology; past-president of the Duval County Medical Association; veteran of World War I; on the staffs of the Baptist Memorial, St. Vincent's, St. Luke's, and Riverside hospitals in Jacksonville; died in Jacksonville Feb. 14, aged 64.

Bowers, James Michael Ⓜ Seattle; University of Michigan Medical School, Ann Arbor, 1925; fellow of the American College of Physicians; clinical assistant professor of medicine at the University of Washington School of Medicine; past-president of the Seattle Academy of Internal Medicine; veteran of World War II; on the staff of the Providence Hospital; died Feb. 9, aged 58.

Brackney, Edwin Leland Ⓜ Windermere, Fla.; the Hahnemann Medical College and Hospital, Chicago, 1915; served as a fellow in surgery and an instructor in surgery at the University of Minnesota Medical School in Minneapolis; later named assistant professor of surgery at the Medical College of Georgia in Augusta; served with the medical corps of the U. S. Army from 1947 to 1949 and from 1950 to 1952; died in Orlando Nov. 13, aged 70.

Ⓜ Indicates Member of the American Medical Association.

Browning, Lawrence T., Peach Creek, W. Va.; University of Louisville (Ky.) School of Medicine, 1926; died Feb. 3, aged 55.

Buckner, Doster Ⓜ Fort Wayne, Ind.; Indiana University School of Medicine, Indianapolis, 1919; member of the American Academy of General Practice; associated with Lutheran and Parkview Memorial hospitals; died Feb. 2, aged 66.

Bukowski, Edward Branislaus Ⓜ Buffalo, N. Y.; born in Buffalo Sept. 29, 1898; University of Buffalo School of Medicine, 1923; specialist certified by the American Board of Preventive Medicine; assistant professor of preventive medicine and public health, University of Buffalo School of Medicine; instructor of public health administration, Syracuse University, from 1941 to 1943; appointed health commissioner of the City of Buffalo in 1947 and in that position helped lay the groundwork for organization of the present Erie County Health Department which took over the city health department in 1948; appointed first deputy commissioner of the Erie County Health Department and held that office until appointed commissioner in April, 1955; died Feb. 21, aged 60.

Burghardt, Michael Ⓜ Brooklyn; Long Island College of Medicine, Brooklyn, 1931; fellow of the American College of Surgeons; veteran of World War II; associated with the Luther Medical Center, Norwegian Hospital, and Prospect Heights Hospital; died Jan. 10, aged 54.

Candela, Rolando Diaz Ⓜ Chicago; Universidad de la Habana Facultad de Medicina y Farmacia, Cuba, 1943; an officer in the medical reserve corps of the U. S. Army from Feb. 12, 1953 to April 30, 1956, interned at the Unity Hospital in Brooklyn; served a residency at the Adelphi Hospital, Brooklyn Women's Hospital, Prospect Heights Hospital, and the Caledonian Hospital, all in Brooklyn; died in the West Side Veterans Hospital Nov. 8, aged 39.

Carlisle, Patrick G., Connersville, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1904; past-president of the Fayette County Board of Health; died in the Fayette Memorial Hospital Dec. 27, aged 80.

Carpenter, Robert Morse Ⓜ Stamford, Conn.; Chicago College of Medicine and Surgery, 1916; veteran of World War I; past-president of the Stamford Medical Society; president of the medical staff at Stamford Hospital and attending physician at St. Joseph's Hospital, where he died Feb. 7, aged 64.

Carpenter, William McNeill Ⓜ Greenville, S. C.; Johns Hopkins University School of Medicine, Baltimore, 1927; certified by the National Board of Medical Examiners; died Feb. 7, aged 56.

Cassidy, William J. Ⓜ Detroit; Detroit College of Medicine, 1908; also a pharmacist; past-president of the Wayne County Medical Society and of the Detroit Academy of Surgery; veteran of World War I; member of the Radiological Society of North America; fellow of the International College of Surgeons; served on the faculty of his alma mater; at various times associated with St. Mary's, Children's, Providence, Mount Carmel, Brent General, Holy Cross, and Delray General hospitals; staff physician for the *Detroit News;* died Feb. 11, aged 78.

Charbonnet, Louis Sr. Ⓜ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1901; for many years on the staff of the Hotel Dieu; died Feb. 3, aged 80.

Cheney, William Whittlesey, Fall City, Wash.; University of Michigan Homeopathic Medical School, Ann Arbor, 1892; also a pharmacist; served on the staff of the Nelems Memorial Hospital in Snoqualmie; died in Redmond Feb. 15, aged 91.

Cherwin, Nathan Hale Ⓜ Los Angeles; Columbia University College of Physicians and Surgeons, New York City, 1924; veteran of World War I; died in Las Vegas, Nev., Dec. 21, aged 59.

Christmann, Paul, Glendale, Calif.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1903; veteran of World War I; served on the staffs of the Behrens Memorial and Glendale hospitals; died in the Veterans Administration Hospital in Los Angeles Dec. 25, aged 79.

Clark, James Walker Ⓜ Durango, Colo.; University of Texas School of Medicine, Galveston, 1941; member of the American Academy of General Practice; served in the medical corps of the U. S. Naval Reserve during World War II; on the staff of the Mercy Hospital; died Feb. 4, aged 43.

Clark, William Henry G., St. Louis; Meharry Medical College, Nashville, Tenn., 1912; died in St. Mary's Infirmary Jan. 20, aged 84.

Cleveland, Frank Mortimer Ⓜ Philadelphia; Jefferson Medical College of Philadelphia, 1899; veteran of World War I; at one time on the faculty of Woman's Medical College of Pennsylvania; on the staff of the Presbyterian Hospital; died in Ambler, Pa., Jan. 29, aged 87.

Colantuono, Julius George Ⓜ Locust Valley, N. Y.; Albany (N. Y.) Medical College, 1946; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War II; lieutenant commander in the medical corps of the U. S. Naval Reserve from 1954 to 1956; on the staffs of the

Community Hospital in Glen Cove, Hillside Hospital, Glen Oaks, and Queen's General Hospital in Jamaica; died Feb. 4, aged 37.

Cooper, William Morris Ⓜ New York City; New York Homeopathic Medical College and Flower Hospital, New York City, 1921; fellow of the American College of Surgeons; formerly adjunct professor of surgery at New York Polyclinic Medical School and Hospital; served on the staffs of the Midtown and St. Clare's hospitals; died Feb. 16, aged 64.

Cornell, Howard Merritt, Albuquerque, N. M.; Kansas City (Mo.) Medical College, 1892; formerly associated with the Indian Service; died in St. Margaret's Hospital, Montgomery, Ala., Feb. 2, aged 88.

Crowe, John Alexander Ⓜ San Francisco; Creighton University School of Medicine, Omaha, 1931; interned at Southern Pacific General Hospital; associated with St. Mary's Hospital, where he died Dec. 20, aged 54.

Curl, Robert Bruce, Toledo, Ohio; Eclectic Medical College, Cincinnati, 1916; served overseas during World War I; formerly associated with the city board of health and the board of education; on the staffs of the Flower and St. Luke's hospitals; died in the Veterans Administration Hospital, Dearborn, Mich., Jan. 29, aged 81.

Darche, Albert A. Ⓜ Westbrook, Maine; Laval University Faculty of Medicine, Quebec, Que., Canada, 1919; served with the Canadian Army during World War I; died in Portland Jan. 13, aged 63.

Davis, Frederick Upham, Fairbault, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; served as health officer of Faribault; veteran of the Spanish-American War; for many years served as the head of the Rice County Selective Service Board; a charter member of the Faribault Chapter of Rotary International and served as the second president of that organization; area council president of the Boy Scouts of America, and was the recipient of the Silver Beaver Award for distinguished service to boyhood; on the staff of St. Lucas Deaconess Hospital; died Jan. 23, aged 83.

De Motte, Roy James Ⓜ Chicago; Rush Medical College, Chicago, 1912; fellow of the American College of Surgeons; on the staff of the Roseland Community Hospital; for many years chief surgeon for the Pullman Standard Car Manufacturing Company; died Feb. 16, aged 77.

Dolan, Martin Aloysius Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1932; associated with the Little Company of Mary, St. George, and Cook County hospitals; died Feb. 19, aged 51.

Eckert, M. Milton Ⓜ New York City; Long Island College Hospital, Brooklyn, 1911; member of the Association of Military Surgeons of the United States; veteran of World War I; died Jan. 11, aged 70.

Eichert, Herbert Ⓜ Miami, Fla.; born in Baltimore May 28, 1907; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1932; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member and past-vice-president of the American College of Cardiology; past-vice-president of the Florida Heart Association; past-president of the Miami Heart Association; clinical associate professor of internal medicine at the University of Miami School of Medicine in Coral Gables, where he was past-secretary of the medical board; veteran of World War II; past-director of cardiology at Jackson Memorial Hospital and chief of staff of the National Children's Cardiac Home; chief of medicine at Mercy Hospital; since 1949 consultant in cardiology at the Veterans Administration; died Feb. 2, aged 51.

Fagin, Joseph Ⓜ Long Beach, Calif.; Long Island College of Medicine, Brooklyn, 1938; interned at the Greenpoint Hospital in Brooklyn; served a residency in obstetrics and gynecology at Henry Ford Hospital in Detroit; specialist certified by the American Board of Obstetrics and Gynecology; member of The Endocrine Society; director of medical research at Ciba Pharmaceutical Company during 1940-1944; associated with St. Mary's Community, and Seaside Memorial hospitals; died Dec. 9, aged 55.

Faragher, James Lawrence Ⓜ Cleveland; Western Reserve University School of Medicine, Cleveland, 1913; fellow of the American College of Surgeons; associated with Marymount Hospital in Garfield Heights, St. Vincent Charity Hospital and St. Alexis Hospital, where he died Feb. 6, aged 69.

Fellows, Walter Lesley, Philadelphia; Hahnemann Medical College of Philadelphia, 1904; died Jan. 14, aged 80.

Franklin, Wellington August, Kinmundy, Ill.; John A. Creighton Medical College, Omaha, 1896; died in Manhattan Beach, Calif., Jan. 1, aged 85.

Galloway, Quince Rudolph Ⓜ Livermore, Calif.; University of Nashville (Tenn.) Medical Department, 1906; died Jan. 29, aged 87.

Gardner, Wray Rodgers Ⓜ Denver; University of Colorado School of Medicine, Denver, 1930; member of the American Psychiatric Association; clinical instructor in psychiatry at his alma mater; past-secretary of the Colorado Neuropsychiatric Society; served as director of mental health for the Colorado

State Public Health Department; veteran of World War II; associated with Mount Airy Hospital; on the staffs of General Rose Memorial, St. Luke's, and St. Joseph's hospitals; died Jan. 28, aged 54.

Glenn, Grover Cleveland Ⓜ State College, Pa.; Eclectic Medical College of the City of New York, 1912; veteran of World War I; died in the Bloomsburg (Pa.) Hospital Jan. 25, aged 72.

Lussier, Joseph Hermenegilde, Springfield, Mass.; Boston University School of Medicine, 1922; interned at the Massachusetts Homeopathic Hospital in Boston; fellow of the American College of Surgeons; veteran of World War I; for many years on the staff of the Mercy Hospital, where he died Jan. 30, aged 61.

McGill, Caroline Ⓜ Gallatin Gateway, Mont.; Johns Hopkins University School of Medicine, Baltimore, 1914; past-president of the Silver Bow County Medical Society; formerly practiced in Butte, where she was on the staff of the Murray Hospital; in October, 1955, was named "Woman of the Year" by the Butte Business and Professional Women's Club; in 1955 awarded an honorary doctor of science degree at Montana State College in Bozeman; died Feb. 4, aged 79.

Miller, James Patton Ⓜ Baltimore; Columbia University College of Physicians and Surgeons, New York City, 1940; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; veteran of World War II; assistant instructor of pathology at the University of Pennsylvania School of Medicine in Philadelphia, 1940-1941; assistant professor of orthopedic surgery at Johns Hopkins University School of Medicine; associated with Johns Hopkins Hospital and James Lawrence Kernan Hospital for Crippled Children; died Feb. 1, aged 45.

Moore, Milton H., Dearborn, Mo.; Ensworth Medical College, St. Joseph, 1896; served three terms as mayor of Dearborn and coroner of Platte County; died in Missouri Methodist Hospital in St. Joseph Jan. 27, aged 87.

Newman, William Manning Ⓜ Spokane, Wash.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; formerly county health officer; honorary staff member of Deaconess, Sacred Heart, and St. Luke's hospitals; died Jan. 11, aged 87.

Patterson, John Norman Ⓜ Burlington, Iowa; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1890; died Jan. 7, aged 94.

Pearson, Fray Owen Ⓜ Macon, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1929; regional director of public health for the state of Georgia; served as director of the Chattanooga-Hamilton County (Tenn.) Health Department; formerly on the staff of the Knoxville, Tenn., health department; died Jan. 9, aged 55.

Pease, Willard A., Rio, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1902; died in Waterloo Jan. 24, aged 82.

Perkins, Robert Donald Ⓜ Moline, Ill.; Rush Medical College, Chicago, 1935; member of the American Urological Association; fellow of the American College of Surgeons; during World War II served overseas in the European Theater for three years; associated with St. Anthony Hospital in Rock Island and the Lutheran Hospital; past-president of the medical staff and chairman of the executive committee of the Moline Public Hospital, where he died Dec. 31, aged 49.

Phillips, Julius Andrew, Minden, La.; Meharry Medical College, Nashville, Tenn., 1927; secretary of the Keystone Life Insurance Company; medical director of the Phillips Hospital, of which he was the owner; died Jan. 12, aged 62.

Pinson, Charles Campbell Ⓜ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1926; fellow of the American College of Surgeons; associated with the Baptist Memorial and the Robert B. Green Memorial hospitals, and the Santa Rosa Hospital, where he died Jan. 1, aged 59.

Projector, Harry Ⓜ Washington, D. C.; University and Bellevue Hospital Medical College, New York City, 1913; for many years practiced in New York City, where he was on the staff of the Bronx Hospital; died Jan. 29, aged 74.

Propst, Duane Willard Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1919; formerly on the faculty of his alma mater; author of "The Patient Is the Unit of Practice"; died in the Presbyterian-St. Luke's Hospital Feb. 2, aged 67.

Rader, John Franklin Ⓜ Houston, Texas; University of Texas School of Medicine, Galveston, 1926; veteran of World War I; co-founder of the Parkview Hospital, where he died Jan. 27, aged 61.

Reis, Abilio Gomez da Silva Ⓜ Piedmont, Calif.; Universidade de Lisboa Faculdade de Medicina, Portugal, 1919; fellow of the International College of Surgeons and the American College of Surgeons; member of the staff of the Peralta Hospital in Oakland; died Feb. 1, aged 66.

Ritenour, Almer Daniel Ⓜ Jamestown, Ohio; University of Cincinnati College of Medicine, 1922; served as president of the Greene County Board of Health; associated with the Greene Memorial Hospital in Xenia, where he died Jan. 24, aged 69.

Rosenberg, Lionel, Brooklyn; Long Island College Hospital, Brooklyn, 1907; specialist certified by the American Board of Internal Medicine; associate clinical professor of medicine at the New York Medical College, Flower and Fifth Avenue Hospitals, New York City; died Feb. 6, aged 75.

Rosenstein, Harry, New York City; Fordham University School of Medicine, New York City, 1917; served overseas during World War I; on the staffs of the Misericordia Hospital and the Lebanon Hospital, where he died Jan. 30, aged 66.

Rossow, Russell Julius Ⓜ Evansville, Ind.; Washington University School of Medicine, St. Louis, 1939; member of the American Academy of General Practice; past-treasurer of the Vanderburgh County Medical Society; past-president of the Baptist Hospital staff; died in the Vanderbilt University Hospital, Nashville, Tenn., Jan. 10, aged 56.

Rowley, Philip William, Dunedin, Fla.; Tufts College Medical School, Boston, 1918; formerly practiced in Gloucester, Mass., where he was on the staff of the Addison Gilbert Hospital; died in the Mease Hospital Jan. 17, aged 65.

Ruoff, Andrew C. Ⓜ Union City, N. J.; Fordham University School of Medicine, New York City, 1917; also a lawyer; taught medical jurisprudence at John Marshall College; on the courtesy staff of the North Hudson Hospital; died in the Doctors Hospital in New York City Jan. 21, aged 65.

Savage, Francis Joseph Ⓜ St. Paul, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; past-president of the Minnesota State Medical Association and the Ramsey County Medical Society; from 1940 to 1947 member of the House of Delegates of the American Medical Association; fellow of the American College of Surgeons; veteran of World War I; associated with St. Luke's Hospital; for many years a surgeon for the Great Northern Railway; died Jan. 16, aged 83.

Schilback, Harold Fenwick, New Milford, Conn.; Long Island College of Medicine, Brooklyn, 1932; specialist certified by the American Board of Ophthalmology; formerly practiced in Brooklyn, where he was on the staffs of the Brooklyn Eye and Ear Hospital and Long Island College Hospital; on the staff of the New Milford Hospital; died in New Haven Hospital Jan. 14, aged 58.

Schoonmaker, Guy Daniel Ⓜ San Francisco; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; member of the American Academy of General Practice; died Jan. 14, aged 67.

Schrup, Joseph Henry Ⓜ Dubuque, Iowa; Northwestern University Medical School, Chicago, 1904; veteran of World War I; associated with Finley and St. Joseph Mercy hospitals; died Jan. 10, aged 76.

Seeley, Isaac Flood, Tucson, Ariz.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1904; died in Tucson Medical Center Jan. 3, aged 77.

Seidelmann, Otto Frank Ⓜ Chicago Heights, Ill.; Chicago Medical School, 1941; veteran of World War II; associated with St. James Hospital, where he died Jan. 29, aged 44.

Sekiyama, Isami Ⓜ Los Angeles; Tohoku Imperial University Medical Faculty, Sendai, Japan, 1915; died Jan. 19, aged 67.

Shearer, Amon Robert Ⓜ Mont Belview, Texas; University of Texas School of Medicine, Galveston, 1898; past-president of the Liberty–Chambers Counties Medical Society; assistant county health officer; died in the Polk County Hospital, Livingston, Jan. 16, aged 87.

Sherard, Stuart Baskin Ⓜ Gaffney, S. C.; University of Maryland School of Medicine, Baltimore, 1905; past-president of the Cherokee County Medical Society; associated with the Cherokee County Memorial Hospital; died Jan. 2, aged 79.

Sherwood, William Davies Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1906; specialist certified by the American Board of Psychiatry and Neurology; served in France during World War I; formerly on the faculty of the New York Post-Graduate Medical School, Columbia University; fellow of the Academy of Compensation Medicine and the New York Society for Clinical Psychiatry; associated with the University and Willard Parker hospitals died Feb. 1, aged 76.

Simons, Harold R., San Francisco, Calif.; Loyola University School of Medicine, Chicago, 1929; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the International College of Surgeons; resigned from the regular Navy in 1931; veteran of World War II; on the staff of Greens' Eye Hospital; chief, department of ophthalmology, Kaiser Foundation Hospital, where he died Jan. 13, aged 56.

Slosser, Dyle Jason Ⓜ Defiance, Ohio; Starling–Ohio Medical College, Columbus, 1913; member of the House of Delegates of the American Medical Association in 1946; since 1945 coroner of Defiance County; past-president of the Ohio Coroners Association and the Defiance County Medical Society, which he also served at one time as secretary; formerly secretary of the Northwestern Ohio Medical Society; member of the American Academy of General Practice; served during World War I; on the staff of the Defiance Hospital; died Jan. 15, aged 75.

Snyder, William Joseph Kline Ⓜ Avalon, Pa.; Bellevue Hospital Medical College, New York City, 1895; served as president of the school board; for many years associated with the Suburban General Hospital in Bellevue, which he helped organize; a founder, and for many years president and chairman of the board, Avalon Bank; died Jan. 20, aged 94.

Spinner, Samuel Leonard Ⓜ Elizabeth, N. J.; L.M.S., & M.A.S., England, 1917; veteran of World War I; on the staff of the Newark Beth Israel Hospital; died in Elizabeth General Hospital Jan. 20, aged 68.

Stangland, Arthur K. Ⓜ Highland, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; associated with the West Surburban Hospital in Oak Park, Ill.; died Jan. 27, aged 78.

Staniford, Kenneth Jamison Ⓜ Bass Lake, Calif.; Cooper Medical College, San Francisco, 1911; past-president of the Fresno County Medical Society; served on the Fresno County Board of Health; was a member of the city parks commission; veteran of World War I; died Jan. 25, aged 69.

Stauffer, Leslie John Ⓜ Bothell, Wash.; Northwestern University Medical School, Chicago, 1910; member of the American Academy of General Practice and the Industrial Medical Association; formerly associated with the Indian Service; died Jan. 19, aged 74.

Stayton, Howard Nehemiah Jr. Ⓜ Newark, Del.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1940; plant physician of the Chrysler Corporation for seven years; formerly member of the state board of health; at one time practiced in Lewes, where he served on the staff of the Beebe Hospital; died Jan. 23, aged 44.

Stoumen, Samuel Ⓜ Bethlehem, Pa.; Maryland Medical College, Baltimore, 1911; served as deputy coroner of Northampton County; on the staff of St. Luke's Hospital, where he died Feb. 4, aged 71.

Swanson, Cleary Neil Ⓜ Detroit; Harvard Medical School, Boston, 1923; clinical assistant professor of obstetrics and gynecology at Wayne University College of Medicine; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; past-president of the Michigan Society of Obstetricians and Gynecologists and the Michigan Obstetrical Society; associated with the Highland Park (Mich.) General Hospital; for many years head of the department of obstetrics and gynecology at Mount Carmel Mercy Hospital, where he died Jan. 21, aged 61.

Swinney, Roy Goldson, Richland, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905; past-president of the Keokuk and Jefferson Counties Medical societies; for many years member of the school board; for a time chief of the medical staff at the Jefferson County Hospital in Fairfield; during World War II served in the state guard; died in the Ottumwa (Iowa) Hospital Jan. 2, aged 77.

Thompson, William Augustas Ⓜ Citronelle, Ala.; University of Tennessee Medical Department, Nashville, 1904; member of the American Academy of General Practice; served as mayor; died Jan. 21, aged 75.

Tint, Louis Jacob Ⓜ Chicago; Jefferson Medical College of Philadelphia, 1908; member of the American Academy of General Practice; veteran of World War I; died in the Albert Merritt Billings Hospital Feb. 3, aged 79.

Vail, George Francis, Hartford, Conn.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; associated with McCook Memorial and St. Francis hospitals, and the Hartford Hospital, where he died Jan. 8, aged 80.

Vassey, Thomas, Trenton, N. C.; University of Tennessee College of Medicine, Memphis, 1938; served an internship at the Norfolk General Hospital in Norfolk, Va., and a residency at the Leigh Memorial Hospital in Norfolk, Va., died Jan. 1, aged 47.

Ward, Edward, Flushing, N. Y.; Jefferson Medical College of Philadelphia, 1923; served on the staff of the Flushing Hospital; died Jan. 5, aged 59.

Webb, Byford Hodgen Ⓜ West Frankfort, Ill.; St. Louis University School of Medicine, 1906; veteran of World War I, serving with the American Expeditionary Forces in Europe; died in the Franklin Hospital, Benton, Jan. 21, aged 77.

Webster, Howard Hamilton, Dayton, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1903; died Jan. 24, aged 78.

Whitmore, William Harvey Ⓜ Captain, U. S. Navy, retired, Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1916; entered the Navy in 1917 and retired July 1, 1938; veteran of World Wars I and II; past-president of the Radiological Society of Virginia; on the staffs of the Norfolk General and De Paul hospitals; died Jan. 30, aged 66.

Woodward, Lee Roy Ⓜ Mason City, Iowa; Rush Medical College, Chicago, 1917; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past-president of the Iowa State Medical Society; on the staff of the Park Hospital, where he died Dec. 9, aged 73.

FOREIGN LETTERS

BRAZIL

Tuberculous Meningitis.—João Batista dos Reis and co-workers of the University of São Paulo (*O Hospital*, vol. 55, January, 1959) compared the results of treatment in 14 patients who had tuberculous meningitis with those in an earlier series of 16 patients who were successfully treated with systemic and intrathecal doses of streptomycin. In the earlier series spinal fluid examinations were performed monthly during the whole treatment. None of the patients developed serious neurological or psychiatric complications. In the later series, in addition to streptomycin, the patients were given isoniazid and ACTH. In the second group the fibrin clot was absent from the spinal fluid in the 6th month as compared to the 14th month in the first group; the cell count became normal in the 8th month as compared to the 14th month in the first group; the protein level became normal in the 5th month as compared to the 10th month in the first group; and the sugar level became normal in the 4th month as compared to the 6th month in the first group. These findings demonstrated the value of adding isoniazid and ACTH to the therapeutic regimen.

DENMARK

Ornithosis-Related Antigens.—Soluble ornithosis-related antigens were obtained from 22 of 30 strains of Bacillus anitratum by Volkert and Matthiesen (*Acta path. et microbiol. scandinav.* 44:278-286, 1958). Antigen-antibody analyses with these antigens and five representative human ornithosis serums revealed certain differences in both the quality of the antigens and the antibodies. Ornithosis antigens and antigens from selected bacterial strains were tested against 172 human ornithosis serums, and 96% of the serums gave positive complement-fixation tests with all antigens. In 89% equal antibody titers were obtained. The ornithosis-related antigens were also tested with 500 ornithosis-negative serums originating from patients suffering from acute infectious diseases. Of these 3% gave positive complement-fixation reactions with the bacterial antigen only. The problem of false-positive serum reactions due to the use of B. anitratum antigen in the diagnostic tests for ornithosis is still unsolved, and until this has been investigated further the practical value of the B. anitratum antigen cannot be determined.

Vitamin B_{12} Deficiency in Anemia.—Determination of the vitamin B_{12} level in plasma was performed on 40 patients with uncharacteristic macrocytic anemia, whose marrow did not contain typical megaloblasts but a varying number of large erythroblasts or macroblasts and who exhibited, in most cases, maturation disturbances of the myelopoietic system in the form of large metamyelocytes and large hypersegmented neutrophils. This was reported by Kristensen and Gormsen (*Acta med. scandinav.* 162:415-422, 1958). Abnormally low plasma concentrations of the vitamin were common among these patients. Broadly speaking, there was agreement between the degree of the marrow changes and the plasma vitamin B_{12} level, abnormally low levels being found in all patients whose marrow contained numerous giant cells, whereas among the group whose marrow contained only occasional giant cells the level was abnormally low in some and normal in others. Patients with a low plasma vitamin B_{12} concentration responded to parenteral administration of the vitamin.

The study showed that low vitamin B_{12} levels in the plasma, reflecting a deficiency of the vitamin, might be present although the marrow revealed no cells that could be definitely designated as megaloblasts. This supported the assumption that the finding of large metamyelocytes and hypersegmented neutrophils (pernicious anemia neutrophils) in the marrow may be an early histological sign of pernicious anemia. The authors pointed out the significance of being able to make a diagnosis of vitamin B_{12} deficiency before typical changes have appeared in the blood or marrow.

Reserpine for Hypertension.—A. R. Krogsgaard (*Acta med. scandinav.* 162:449-463, 1958) used reserpine to treat 75 patients with benign essential hypertension, the maintenance dose being about 0.5 mg. daily in most cases. In 39 of these treatment was supplemented later by hydralazine, the maximum dose being 400 mg. daily. To elucidate the frequency of the initial side-effects of hydralazine with and without preceding administration of reserpine, 24 patients were treated with hydralazine alone. Reserpine as the only form of treatment gave a satisfactory result (fall in the mean blood pressure of 20 mm. Hg at least and of 140 mm. Hg at most, and abatement of reversible eyeground changes) in 11 of 75 patients. In these 11 patients the blood pressure fell on the average from 209/123 to 161/93 mm. Hg. When a placebo was given after an average duration of treatment

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

of 15.7 months, the mean blood pressure rose by 20 to 37 mm. Hg in six patients but did not change significantly in the remaining five.

Most of the patients who responded satisfactorily to reserpine alone had a less severe hypertension than the others in the series. When reserpine was given prior to and simultaneously with hydralazine fewer side-effects of the latter were seen, and more patients were able to complete the treatment. Furthermore a more rapid rise in the dose of hydralazine became possible. Of the 39 patients treated with reserpine and hydralazine 20 completed the treatment satisfactorily. In these patients the blood pressure fell on the average from 225/127 to 181/97 mm. Hg. When a placebo was given after an average period of combined treatment of 29.5 months, the mean blood pressure rose by 20 to 24 mm. Hg in three patients, by 10 to 19 mm. Hg in eight, and did not change significantly in the remaining nine.

The authors concluded that reserpine as the only form of treatment produced a satisfactory result in a small proportion of patients with benign hypertension, chiefly in the milder forms. In the rest of the patients reserpine might form a valuable basis for combined treatment with hydralazine. After prolonged treatment the administration of reserpine might be tentatively discontinued, as about half the patients would then be able to dispense with this drug.

In the same issue Krogsgaard described the side-effects of reserpine in 36 patients treated with reserpine alone and 39 treated with reserpine combined with hydralazine. Side-effects of reserpine treatment occurred in 60 of the patients. They were insignificant in most cases (nasal congestion, diarrhea, and fatigue) and tended to subside with continued treatment, but in 20 patients treatment had to be discontinued because of edema or other undesirable side-effects. A weight gain occurred in 26 patients amounting maximally to 16.8 kg. (37 lb.) and averaging 7.2 kg. (16 lb.). In only one patient did the increase in weight necessitate discontinuance of treatment. In the course of continued treatment the weight fell again in some of the patients and after cessation of the treatment in most. Mental depression was the severest side-effect, seen in 13 patients. Treatment with reserpine was discontinued in 12 of these. In one patient the mental depression led to suicide. Two patients had to be admitted to psychiatric wards and one of these committed suicide one year later. The patients who developed mental depression had a higher frequency of previous depression than the other patients or had a familial predisposition to this. The dose of reserpine given to the depressed patients often exceeded 1 mg. daily. Pronounced depression in a patient or in his family constituted a contraindication to ambulant treatment with reserpine.

Occupational Allergy.—From 1944 to 1956 4,348 allergic patients suffering from bronchial asthma, vasomotor rhinitis, or angioneurotic edema were examined at the Allergic Clinic, Copenhagen, by Bruun and Lorenzen (*Acta allergol.* 12:432-440, 1958). The authors assumed the following criteria for allergic diseases of occupational origin: (1) the allergic disease must not have been present prior to the work that is considered injurious, (2) the symptoms must chiefly appear during work and always be most pronounced at the place of work, and (3) the patient's condition must improve materially when he is off duty for prolonged periods as, for instance, during holidays. Judging by these criteria 281 patients (6.5%) were found to be suffering from occupational allergy.

New Succinimide for Epileptics.—Trolle and Kiørboe (*Nord. med.* 60:1780-1782 [Dec. 11] 1958) treated 38 patients who had petit mal seizures with PM 680 for periods averaging eight months; 14 became seizure-free, 17 had 50 to 99% reduction in seizure frequency, and 7 showed no improvement. Thirty patients had typical petit mal seizures and only three of these did not react to the treatment. Of six patients with myoclonic fits two became seizure-free, two had clinical improvement, and two did not respond to treatment. Two patients with atypical loss of consciousness showed no improvement. The drug was not given to patients with typical psychomotor epilepsy. In several patients it was found to be superior to both phensuximide and oxyphenbutazone, and side-effects were less frequent.

Treatment of Necrotic Lesions.—Storm and Hilmer-Nielsen (*Nord. med.* 60:1831-1834 [Dec. 18] 1958) used stabilized crystalline trypsin as a powder aerosol on 10 patients with large necrotic lesions and observed a rapid resolution of the necrotic tissue in five or six days. It was impossible to say anything about the course of illness in these patients if the lesions had been treated by other means, but in most of the patients other treatments had been tried without benefit before the trypsin therapy. The two patients in whom the trypsin therapy partially failed had extremely low healing tendencies because of their poor general condition and local nutritional disturbances.

Serum Transaminase Activity.—In 120 patients serial determinations of serum glutamic oxalacetic transaminase and glutamic pyruvic transaminase levels were made and reported on by Ersbak (*Nord. med.* 61:49-54 [Jan. 1] 1959). The possibilities of a more differentiated clinical interpretation were examined on the basis of the curve patterns. The serial determinations of the two transaminases simultaneously demonstrated characteristic changes diagnostic of coronary infarction, metastases to the liver, chronic liver disease, acute parenchymatous liver disease, and occlusive liver disease. Although variations from the characteristic pattern might be seen, serial determinations of the activity of the transaminases were considered to be of greater value than single determinations.

Rubella and Pregnancy.—There has been a marked rise in the incidence of rubella in Denmark. In the period 1950-1952 about 6,000 cases were reported and in 1955, there were 54,815. Because of the risk of malformations in children whose mothers had had rubella at an early stage of their pregnancies, Jacobsen and Christensen of the Odense general hospital (*Ugeskrift for læger*, Jan. 8, 1959) sent a questionnaire to physicians to ascertain the frequency of such malformations. They found that 43 pregnancies had been complicated by rubella, and that among the 32 women whose rubella had occurred within the first 16 weeks of pregnancy 19 had given birth to healthy children and 8 had aborted. In several cases confinement had been normal, but the infants presented such malformations as heart disease, cataract, or defective dental enamel.

Among the 23 women for whom abortion had been induced on account of rubella, 5 had wished to have a child but had been so alarmed by the prospect of malformations that they wished to sacrifice it. Among the 5,400 abortions induced in Denmark in 1955 there were 406 for whom this was done on account of rubella. Jacobsen and Christensen concluded that if rubella occurs in the early months of pregnancy, and if the mother desires the termination of her pregnancy on this account, this wish should be granted. They suggested that, in order to get more statistical information on the subject, under the heading "rubella" in the weekly list of reportable diseases there should be a subheading to be filled in with the coincidence of pregnancy and its duration at the onset of the rubella.

Cancer of the Rectum.—In the 10-year period 1946-1955, there were 180 cases (112 in men and 68 in women) of cancer of the rectum in Aarhus (population of 113,000). These cases were reported on in the *Danish Medical Bulletin* for December, 1958, by Dr. N. Blixenkrone-Möller who calculated that these cases represented an average of one such case per year for every 6,280 persons. Up to the age of 60, the disease was equally distributed between the sexes, but after this age there was a steep rise in men but not in women. In 70% the tumor was situated at most 10 cm. above the anus and could therefore be reached by the exploring finger.

Among the 170 patients whose tumors were examined microscopically, 158 tumors were adenocarcinomas, 6 were solid carcinomas, 5 were malignant papillomas, and 1 was a lymphosarcoma. The tumors were regarded as inoperable in 55 of the total instances and as operable in the remaining 125. Major operations were performed in 78%. Five years after the diagnosis, 31% of the operable patients were still alive. Of the operable patients who underwent rectal resection, 37% were alive five years later. The prognosis proved to be better for those whose symptoms had existed for more than three months than for those with an interval shorter than three months. The author concluded that it was desirable to use a more extensive removal of pelvic connective tissue and perineal skin that has so far been the practice, especially in low-level cancers of the rectum.

Artery Transplantations.—At a meeting of the Jydsk Medicinsk Selskap, reported in *Nordisk medicin* for Feb. 12, Jakobsen and co-workers reported a series of 41 patients on whom arteries had been transplanted at the Aarhus general hospital since 1955. They had been selected from among the 97 patients subjected to arteriography with the possibility in mind of transplantation for the relief of intermittent claudication, pain, necrosis, or gangrene. Most of them had arterial obstruction of the lower limbs, but nine had such an obstruction of the abdominal aorta. In 7 the symptoms had existed for less than six months, and in 14 for over five years. Most were between the ages of 50 and 60, and one was over 80. The grafts had been taken from the young and healthy victims of fatal accidents, seldom more than six to eight hours after death. Among the 38 survivors of the transplantations, 31 were cured or much improved, but, until the complication rate can be effectively reduced, the indications for transplantation must be imperative, the mere arteriographic demonstration of an obstruction being no call for it in the absence of symptoms.

Public Health Data.—Dreyer and Frandsen (*Danish Medical Bulletin*, January, 1959) reviewing the statistical reports for 1956 and 1957 found that the behavior of the reportable diseases was rather erratic, with an increase in influenza from 115,203 in 1956 to 544,613 in 1957. On the other hand the incidence of poliomyelitis fell from 191 (37 paralytic and 154 nonparalytic) in 1956 to 26 (10 paralytic and 16 nonparalytic) in 1957. In neither year was a single case of diphtheria reported. Since 1954 there has been a slight fall in the incidence of gonorrhea, but the figure for 1957 of 7,447 cases is relatively high. About half this number were reported in Copenhagen. The infant mortality continued to fall with 25.2 deaths per 1,000 live births in 1955 and 23.4 in 1957. The two leading causes of death, malignant growths and degenerative cardiovascular disease, accounted for 46% of all the deaths in 1957. The tuberculosis mortality was down in this year to 4.4 per 100,000, with pulmonary tuberculosis accounting for 3.8 per 100,000. The deaths from all forms of tuberculosis amounted to less than a third of the deaths from traffic accidents. There are now 10.15 hospital beds available per 1,000 population, and there is one practicing physician for every 864 of the total population.

Complications of Blood Transfusion.—At the Slagelse general hospital Dr. S. A. V. Jörgensen (*Ugeskrift for læger*, Jan. 22, 1959) investigated the frequency with which transfusion from a blood bank is followed by nonhemolytic reactions as tested by measurements of the temperature of the recipients before and after this operation. During the three-year period 1954-1957, 2,173 of the 4,223 transfusions were controlled by such measurements immediately before and half-hourly for three hours after a transfusion. The reaction was uncomplicated in 67.4%, febrile in 31.1%, and allergic (urticaria or angioneurotic edema) in 1.5%.

When the 233 febrile temperatures before transfusion were subtracted from the total of 677, there remained 444 (or 20.5%) which could be traced to the transfusion. Most of these could be dismissed as trivial, but 3 or 4% with a febrile reaction severe enough to call for preventive measures remained. No alteration in the incidence of reactions was observed after the introduction of infusion apparatus for use only once, but the author is exploring the effects of a routine addition of antihistamine to the blood immediately before a transfusion. Meanwhile the chief merit of the present study has been its demonstration of the great uncertainty over the underlying causes of the reactions to blood transfusion and how to prevent them.

FINLAND

Drug Addiction and Crime.—Westling and Riippa (*Ann. med. int. Fenniae* 47:205-222, 1958) investigated the criminal record of 169 drug addicts (107 men and 62 women) treated at some of the mental hospitals of Helsinki. Of these patients 75% of the men and 40% of the women had committed, at some time in their lives, at least one crime for which they had been sentenced. In a control group made up of men, the corresponding figure was 16.4%. Among persons who had become addicted before the war there was no primarily criminal patient, whereas among those who had become addicted after the war the percentage who were primarily criminals was 42% for men and 15% for women. Both of these groups contained a large number of persons who had committed crimes after having taken to drugs. For the postwar male group the figure was 78%. The crimes that increased after addiction were primarily theft, fraud, smuggling, and forgery. On the other hand, the number of violent acts remained practically unchanged. The number of these persons who had committed acts of violence must, however, be considered exceedingly high (about 20% of the men). About 60% of primarily noncriminal addicts committed some crime in the course of the eight years after addiction. Among physicians who had become addicts the percentage committing crimes was far below the average. Primary as well as secondary criminality attained the higher figures, the younger the persons were when they became addicted to drugs. The more accidental the reason for addiction, i. e., the more powerfully it had been motivated by a desire for euphoria, the more accentuated was the criminality.

Reserpine and Vascular Changes Caused by Smoking.—Experiments with 18 healthy subjects confirmed that smoking one cigarette increased the heart rate and the systolic blood pressure and decreased the cutaneous temperature of the foot. Iisalo and Kärki (*Ann. med. exper. et biol. Fenniae* 36:343-349, 1958) gave these subjects 1.0 to 1.5 mg. of reserpine a day for three or four days and observed that smoking increased the heart rate and lowered the cutaneous temperature significantly less under reserpine treatment than in the control experiments without reserpine.

Methanol Poisoning.—A. R. Alha and co-workers (*Ann. med. exper. et biol. Fenniae*, 36:444-455, 1958) attempted to ascertain whether in forensic practice it would be possible to use the determination of formic acid in brain, kidney, liver, and blood as a criterion of methanol poisoning, if no urine was available. In the estimation of formic acid, distillation in steam was used for the isolation and the oxidative reaction with mercuric chloride for the determination, the yield of mercurous chloride being measured gravimetrically. The yield was found to be 70 to 90% in the urine, brain, and kidneys. By contrast, the liver and, in particular, the blood gave smaller yields. In addition, "normal" formic acid concentrations were found to be 5 mg. or less per 100 Gm. In 10 fatal cases of methanol poisoning the formic acid concentration in the organs examined was markedly higher than "normal." In all cases methanol was qualitatively demonstrated in a steam distillate of mixed viscera. This investigation showed that for the detection of acute methanol poisoning it was often sufficient in forensic medicine, when methanol had been qualitatively detected in the body, to prove that the concentration of formic acid was increased in the urine or, if urine was not available, in the viscera, preferably the brain or kidneys.

Smoking, Serum Cholesterol, Blood Pressure, and Obesity.—Keys and Brozek, with the collaboration of Finnish workers (*Lancet* 1:492, 1959), examined the effect of cigarette smoking on serum cholesterol levels, blood pressure, and obesity in 360 male smokers and 165 male nonsmokers in Helsinki and the rural districts of west and east Finland. They reported that in all regions and in all age groups, except in those aged 50 to 59 in west Finland, smokers had a higher average serum cholesterol level than nonsmokers. Among smokers those who smoked most tended to have the highest serum cholesterol level. At all ages and in all regions in Finland smokers tended to have slightly lower blood pressures than nonsmokers, although the difference between them was small. In both rural areas the smokers tended to be slightly thinner than the nonsmokers, although in Helsinki there was no clear relation between smoking and obesity. The authors pointed out that their data did not explain the origin of the differences in serum cholesterol levels, blood pressure, and body fat. They could not, therefore, conclude that habitual cigarette smoking caused the serum cholesterol level to rise, the blood pressure to fall, or the body to lose fat. Brozek and Keys in another study found that men who stopped smoking tended to become fatter, an observation in keeping with the general view that smoking curbs the appetite.

NETHERLANDS

Diabetic Survey.—J. D. Mulder and E. van de Weg (*Huisarts en Wetenschap*, p. 66, December, 1958) made a survey for undetected diabetes in three districts with a total population of about 31,700. The preliminary screening was made with Clinistix and, if glycosuria was suspected, a glucose tolerance test was made. In one district (about 10,000 people) 0.41% were found to have undetected diabetes. In the second district (about 14,000 people) the percentage was 0.22, and in the third (7,700) it was 0.19. The wide variation of the percentages obtained in these three districts might be due partly to analytical errors made in districts 2 and 3. On the whole, however, these figures are much smaller than those reported in other countries. Of the 88 patients whose diabetes was thus detected, 3 were between the age of 20 and 40; 32 were between 40 and 60; and 53 were over 60. In most the diabetes was mild but in 31 the fasting blood sugar level appeared to be more than 300 mg. per 100 ml.

The Reliability of the Differential Leukocyte Count.—C. L. Rümke and C. van Eeden (*Nederl. tijdschr. geneesk. 102:2505, 1958*) discussed the reliability of the differential leukocyte count. They first considered whether the smears were correctly made. The variability can be calculated statistically. When, for example, the blood contains 4% band-form neutrophils, the percentage found by counting 200 cells will vary in 95% of cases between 1 and 8%. In the remaining 5% a much larger deviation may be encountered. This variation will depend on the percentage present in the blood of the type of cells counted and on the total number of cells counted. By counting 200 cells of blood which contains 50% lymphocytes, the variability will be in 95% of cases between 39 and 61%. By counting 1,000 cells, this variation will be 46 to 54%. Mostly, however, the physician will be interested in the opposite: what is the reliability of the figures obtained? It is impossible to give exact figures, but it is possible to find 95% confidence limits. When 200 cells are counted and none of one type of cell is found, this means that up to 4% of that type of cell may be present. When 5% are found this means that from 1 to 12% may be present. For 10%, these figures are 4 and 18; for 25%, 16 and 35; and for 50%, 39 and 61.

Hemolytic Streptococci in Children.—H. C. Zanen and S. Wagenaar (*Nederl. tijdschr. geneesk.* 102:1198, 1958) investigated the prevalence of group A hemolytic streptococci in healthy inmates of a children's home. The children, ranging from 2 to 7 years, were examined fortnightly over a period of two years. On the average 50% of the tests were positive. In the summer only a few children (about 2%) appeared to be infected. In the winter at times up to 100% of the tests were positive. In the two-year period there were seven epidemics, all of which were caused by different strains. On the average, 10% of the new infections were attended with illness. Each child had about three subclinical infections with a new type of the group A hemolytic streptococcus annually. In only two instances was a new infection observed with the same strain within four months. On the average each child had suffered every three or four years from a streptococcic illness.

Type 14 caused all of the 3 cases of scarlet fever and 7 of 13 other streptococcic illnesses observed in these children. This type was found in 40% of the 510 patients with scarlet fever who were treated in Amsterdam during the same period. This suggests an increased pathogenicity for this strain at the time of this investigation. In two children illness was caused by type 28; in two by type 12; in one by type 4/26; and in one by type 1. In view of the repeated occurrence of group A hemolytic streptococci in children, a positive culture is not believed to be of much clinical significance. The use of penicillin against streptococci should be limited to severe clinical infections and to the prevention of recurrent rheumatic fever. No purpose is served by keeping healthy carriers home from school.

A New Periodical.—In November, 1958, a new periodical, *Spreekuur thuis* (The Doctor at Home), made its appearance. It is issued by the Netherlands Medical Association to give the lay population information about health and medical science. The editor called attention to the increasing desire of the people to be fully informed about such problems. In view of the importance of good and reliable information, the association thought it wise to issue a magazine to which many specialists would contribute.

SWEDEN

Armchair Treatment for Cardiac Infarction.—Sture Helander (*Acta med. scandinav.* 162:351-359, 1958) reported on one series of 112 patients treated in an armchair and given anticoagulants and another series of 100 patients treated in an armchair without anticoagulants. In the first group the mortality was 10%, compared with 15% in the second group. A third series of 80 patients was treated with rest and anticoagulants, with the resulting mortality of 26%. The aim of the armchair treatment was not to increase the effort of the patients, but, on the contrary, to ease the burden of the heart muscle. The distribution of cases of cardiac infarction with regard to their severity was reasonably comparable in all three groups, with a somewhat lower percentage of severe cardiac infarction in the armchair group receiving anticoagulants. Most of those who died showed ominous prognostic signs such as arrhythmia or heart block. About half of the patients had had one previous attack of cardiac infarction as shown at autopsy. Of the 25 patients who were treated in an armchair and who died, 14 had had previous attacks. The frequency of embolic complications was negligible in all groups and was not thought to have had any effect on the issue. Armchair treatment seemed to constitute a good prophylactic measure against embolic complications and it seemed probable that it was sufficient to treat only the bad prognostic risks (those with arrhythmias, heart block, and cardiac failure) with anticoagulants.

Subarachnoid Hemorrhage.—Olle Höök (*Acta med. scandinav.* 162:475-492, 1958) reported a series of 152 patients who had subarachnoid hemorrhage and who were admitted within no more than one week after the hemorrhage. More than 90% were admitted in the first or second day of illness. The author suggested the classification of the patients in special risk groups, thereby greatly increasing the possibility of comparing material from different investigations. He also pointed out that patients with subarachnoid hemorrhage from different hospitals could not be considered congruent entities from the prognostic point of view even though, on the whole, they might be of the same degree of severity because such factors as age and treatment might vary according to the type of hospital. The mortality was highest on the first day, had decreased appreciably after the first two weeks, and was much lower after eight weeks. In from 10 to 15% of the patients the cerebral damage caused by the hemorrhage was of such magnitude that most were beyond help from any kind of therapy. The late prognosis was much better for the groups operated on than for those treated conservatively.

In the same issue Olle Höök reviewed a series of 138 patients with subarachnoid hemorrhage in which no aneurysm was revealed by angiography. Of these patients, 136 were followed for an average of 4.5 years. The average age at the time of admission to the hospital was 43 years and the sexes were evenly divided. The symptoms were usually relatively mild and 67% of the patients presented no focal neurological signs. The late prognosis with respect to recurrent fatal hemorrhage was favorable, with an incidence of 6%.

Causes of these hemorrhages were varied. With few exceptions, the investigations were complemented with vertebral angiography if the symptoms indicated that the basilar region was involved. In isolated cases arterial aneurysms may completely thrombose, making it impossible to trace them angiographically. In some patients a primary intracerebral hemorrhage appeared to have occurred with penetration of the hemorrhage into the ventricular system and/or to the surface of the brain in the subarachnoid space. This accounted for only 7% of the present series, however. The possibility of spinal subarachnoid hemorrhage, which is often difficult to distinguish from intracranial bleeding, should be considered. If the pain is initially localized in the back and radiates to the arms or legs, there is a fair possibility of spinal hemorrhage. Spinal subarachnoid hemorrhages usually arise from vascular tumors and malformations but are occasionally associated with other types of tumor such as sarcoma, ependymona, and neurinoma.

In suspected vascular malformations in the cervical and upper thoracic spinal cord, vertebral angiography may give valuable information. Vertebral angiography is indicated in subarachnoid hemorrhage when bilateral carotid angiography fails to show any source of the bleeding (1) if there are any neurological symptoms from the vertebral-basilar region, (2) in young patients, and (3) in recurrent hemorrhages. In this series 10 of the patients died. Autopsy, performed on five of these, revealed arterial aneurysms in two. One of these aneurysms was situated on the basilar artery and had not previously been visualized in the angiogram.

Spondylolisthesis.—The relationship between the lesions and the symptoms in spondylolisthesis was studied by Gösta Kollberg (*Nord. med.* 60:1778-1780 [Dec. 11] 1958) who stated that disk degeneration, rupture of a disk, and narrowing of the intervertebral foramina have one factor in common which could produce an increase in the symptoms, namely, abnormal mobility (instability) between the vertebrae. In a series of patients with spondylolisthesis of L_5 and S_1, the instability of L_5 and S_1 did not markedly influence the degree of severity of the subjective symptoms.

Burns.—Gunnar Birke and co-workers (*Nord. med.* 60:1824-1828 [Dec. 18] 1958) stated that an extensive burn could not be regarded as a lesion involving the skin only. It causes pathophysiological disorders in the whole body and is often accompanied by severe bacteriological complications. After an extensive burn large amounts of albumin are lost from the circulation, particularly in the early phase. There is also an abnormal distribution of albumin in the body, with accumulation of albumin especially in the subcutaneous tissue. In the first 24-hour period there is, in addition, hemoconcentration, increased destruction of blood cells, hyperkalemia, and acidosis. Later the hyperkalemia is often succeeded by hypokalemia. The sodium content of the blood varies from patient to patient, depending on the manner in which the fluid replacement is carried out. Urinary excretion of histamine, epinephrine, levarterenol, and corticosteroids is greatly increased at first and, excepting that of histamine which is normalized in 24 to 48 hours, it remains raised throughout the first week.

Cardiac catheterization was performed in a number of patients and in shock it provided valuable information to aid the differential diagnosis between hypovolemic shock and primary cardiac insufficiency. The tendency to pulmonary edema, which is present during the so-called absorption phase, does not seem to be associated with heart failure, but is probably a manifestation of capillary damage in the lungs, with a change in permeability on the basis of a direct burn or, possibly, caused by humoral factors or infection. Bacteriological studies have shown that in cases of infection in the skin lesions the first symptoms appear as a rule after the second day, and that staphylococci and gram-negative rods are the most important causative agents. Infections resistant to treatment and due to bacterial strains occurring in the hospital play a predominant role in these patients. In about 50% of those who die, infections, mainly in the form of bronchopneumonia and sepsis, are a contributory cause of death.

In the same issue these authors stated that during the acute phase in the course of extensive burns, intravenous replacement therapy is essential to prevent hypovolemic shock. Dextran is an excellent plasma expander, but in third degree burns involving more than 20% of the body surface whole blood should also be given and, if possible, albumin as well. Sodium bicarbonate and glucose should also be given at first. After 48 hours the sodium intake should be restricted and potassium given instead. Oxygen inhalations combined with careful checking of the ventilation is important in patients with pulmonary complications. Antihistamines should be given, but corticotropin is rarely indicated. Measures to prevent infection are important and should include isolation of the patient and treatment under aseptic conditions. When infection occurs, bacteriological examination with determination of antibiotic resistance should first be made. Antibiotics should be given in an adequate dose, preferably by the intravenous route. Excision and skin grafting of third degree burns should be performed as early as possible. The importance of centralization of the treatment of burns in a special center is stressed.

Sideropenia.—Ian Lundholm (*Nord. med.* 61:7-13 [Jan. 1] 1959) reported on a follow-up of 123 patients with hypochromic anemia of whom 117 were women. These patients were first seen in 1939. Two patients had developed cancer of the hypopharynx and one a sublingual cancer, which was cured. Of 80 who died one had cancer of the esophagus. The incidence of recurrence was high. Of the entire series 60 patients had a total of 142 relapses. The more severe ones were induced by acute causes, especially hemorrhage. Restoration to normochromia occurred only gradually with increasing age, probably indicating a slow building up of the depot iron. The irreversibility of the symptoms of sideropenia was higher in the patients who initially sought medical advice for their anemia only and in those who were traced secondarily through family members than in the rest who were incidentally discovered to have the disease. This was interpreted as evidence of a constitutional hereditary factor. A similar clinical course in three pairs of monozygous twins gave further support to the hypothesis advanced in 1939 that a dominant gene determines the tendency to inadequate absorption of iron, a tendency that is revealed in particular when large amounts of iron are lost by hemorrhage.

It was observed that 10.6% of all the patients and 26% of those with stationary achlorhydria had an acquired pernicious anemia. The incidence of this condition in the normal population is about 0.2%. Membranes in the hypopharynx were found in 20 patients. These were considered as especially disposed to cancer. The membranes were more resistant to iron therapy than were the other manifestations. Animal-protein deficiency was found in 38% of the patients at the initial examination but in only 10% of those followed up. Only a few showed a marginal intake of iron at the initial examination. Hereditary factors, marginal intake of iron in the food, and pathological bleeding have in adolescent girls been found likely to give rise to sideropenia, which will then recur with any slight extra demands on the iron depots.

Cholecystokinin in Cholecystography.—Tomenius and Backlund (*Nord. med.* 61:41-47 [Jan. 8] 1959) stated that preparations of cholecystokinin (CCK) corresponding to 0.04 mg. of substance per kilogram of body weight, a total of 3 mg. in adults, were injected intravenously in 650 patients in connection with cholecystography. Contraction of the contrast [illegible] and visualization of the bile duct was produced within 2 minutes, with a maximum after 15 to 20 minutes. In a series of 59 patients, the effect of the cholecystokinin test was compared with that of the egg-yolk meal, both tests being performed on these patients. The former test was found to be superior to the egg-yolk meal in that it saved time and was more reliable, particularly for visualizing the cystic duct and common bile duct. In 8 of the 59 patients the contrast medium-filled gallbladder did not respond to either stimulant. The CCK test was found to reduce the time necessary for cholecystographic analysis to one-fourth of that required by the egg-yolk meal. No severe side-effects were noticed. A further analysis of 612 patients who were examined later was made, and the phenomenon of good contrast medium filling without any visible stones combined with poor contraction of the gallbladder was also reported. A roentgenologic examination of the stomach can be made at the same time. Stones of the ductus choledochus were evacuated during cholangiography in one patient with CCK.

Ataraxics for Mental Patients.—In 1957 Bo Rydberg (*Nord. Med.* 61:93-95 [Jan. 15] 1959) started using ataraxics in treating 26 patients who were extremely dangerous to other persons in a maximum security pavilion. Such a pavilion requires special technical safety arrangements and a big nursing staff. Chlorpromazine, reserpine, perphenazine, and other drugs alone or in combination were used. After determining the maintenance dosage in each case, the patients were treated for 6 to 12 months. The results of this treatment were classified as not improved, distinctly improved, much improved, and greatly improved. Greatly improved meant that the patient could be kept in an ordinary mental hospital. Of these 26 patients 4 were in this category, 11 were much improved, 10 distinctly improved, and 1 not improved. One patient was actually transferred to an ordinary mental hospital and was working regularly when last observed. As a result of treatment the tension in the pavilion was greatly reduced. This was a relief to the staff and might even allow a reduction in their number.

Dystocia Eased by Vacuum Extractor.—O. G. A. Berggren (*Svenska läk.* 51:3715-3732, 1958) at the Linköping Obstetrical Clinic used a Malmström vacuum extractor as a substitute for forceps in difficult labor. Although the principle of the extractor had been known since the 18th century, it was only with the modification invented by Dr. Malmström in 1956 that any truly superior results were gained with it as compared with those when the forceps was used. Swedish experts believe that the use of the new instrument will reduce the number of cases of cerebral palsy. Two groups of women delivered with forceps and their children were studied and compared with a group of suction-delivered patients, a total of 150 deliveries. Not only was the new method more gentle on the child but also it speeded up labor and gave rise to far fewer serious perineal tears (26% perineotomies as against between 83 and 94% with forceps) or other complications.

As a rule the operation was over in a few minutes and the average postdelivery time was reduced to 8.7 days as compared with 12.7 days when a forceps was used. Vacuum extraction was suitable also as a substitute for certain types of cesarean section. An additional advantage is the possibility of reducing the delivery staff for, as opposed to the forceps method, the use of the Malmström instrument requires no anesthetization. The vacuum extractor on the contrary acts as a stimulus on the natural labor contractions. The synchronous application of the vacuum power and the voluntary labor movements of the mother make it possible to arrive at a process which more nearly approaches physiological delivery. This in turn, gives the child's head a chance to recover from the strain of passing through the birth canal. The Malmström instrument has all-metal suction cups. There are three sizes so as to permit reaching the head even when it is arrested in the upper sections of the pelvis. This is another clear advantage over forceps, which are difficult to apply in patients with a narrow pelvis.

Congenital Dislocation of the Hip.—Dr. S von Rosen of the Malmö General Hospital (*Nordisk Medicin*, Jan. 15, 1959) stated that since 1952 every baby has been tested shortly after birth by the Ortolani snap sign, a sensation evoked at the hip by a manipulative movement. By 1956 he was able to report on eight babies with 14 snapping hips. Roentgenograms showed upward displacement of the femur, indicative of dislocation, for which various forms of postural treatment were prescribed. In only two of these cases was it necessary to put the infant in a plaster cast for a brief period. In the other cases only ambulant treatment was required. In every case treatment was completed and the child could begin to walk when about a year old. Follow-up roentgenographic control showed normal or nearly normal development of the hips. Since 1956 six more cases have been discovered in this way and given appropriate treatment. As no other case of congenital dislocation of the hip has been discovered in Malmö during the period under review, it may be claimed that the above-mentioned procedure has proved effective in detecting this condition at birth. Improved x-ray technique with regard to both diagnosis and subsequent supervision has enabled von Rosen to shorten the fixation period.

Sympathectomy for Obliterative Arteritis.—Between 1930 and 1955 sympathectomy for obliterative arteritis was performed on 104 patients (88 men and 16 women) at the Serafimer Hospital in Stockholm. Dr. A. Kövamees (*Nordisk Medicin,* Jan. 22, 1959) made a follow-up study of these patients. Their average age at the time of operation was 53 years. The operation was undertaken to relieve intermittent claudication, pains and cramps at night, gangrene, or a sense of coldness in the limbs provoked by arteriosclerosis or diabetes. At first the operation was transabdominal but later on it was performed extraperitoneally. The operation was performed in two stages when it had to be bilateral. No deaths were attributable to the operation. Only four patients could not be traced. Of the rest 30 had died before the follow-up, which showed that for the most part even elderly patients had tolerated the operation well. Lasting improvement of claudication by itself or in combination with pain was most marked when it was associated with an efficient collateral circulation which should be a prerequisite for the operation in such patients.

Care of the Insane.—Reports of the proceedings of the Swedish Parliament give a good insight into what is happening in the country's state-owned mental hospitals. With more beds and a more rapid turnover of patients reflecting the success of modern methods of treatment, the number of admissions has risen from about 8,000 in 1950 to over 13,000 in 1957. There are now more acute cases and fewer chronic cases, with a steadily dwindling incidence during the last decades in the number of patients with schizophrenia and manic-depressive psychosis and a rise in the number of those with reactive psychosis, neurosis, psychopathy, alcoholic hallucinosis, and similar ailments. In the past many of those with acute conditions were not admitted to any mental hospital for such reasons as the deterrent effect of long waiting lists.

Willingness on the part of the patient to seek treatment in a mental hospital has increased. In 1940 barely 37% of the admissions were at the patient's request, whereas the corresponding figure for 1956 was 48%. Senile psychoses, so difficult to treat and so apt to be of long standing, continue to require from 20 to 25% of the mental hospital beds. Over 50% of them are still required for chronic conditions such as schizophrenia, but the outlook for them has improved, thanks to new methods of treatment sometimes helpful even in cases of long standing; but, although modern methods may have speeded up the turnover, the successes thus achieved have often been costly. The growing flood of acute cases now requires a complicated and costly set-up for both diagnosis and treatment, whether in the form of chemical laboratories or in the training of physicians in modern methods of psychological testing.

Functional Heart Diseases.—Since 1948 the Kristianstad Army Hospital has included a special department for dealing with functional heart diseases. Dr. G. Trönnberg (*Svenska Läkartidningen,* Feb. 6, 1959) reported a follow-up study of 164 young men who in earlier years had had a functional heart disease. These disturbances manifested themselves by dyspnea, palpitation, a precordial stabbing pain on exertion or even at rest, lassitude, or anxiety. Among the 145 who answered the questionnaire sent them were 41 who came to the hospital for reexamination. This showed that 16 had become subjectively free of symptoms. The objective picture was practically unchanged, although on the whole there had been some reduction of the blood pressure. The family histories indicated heredity as a potent influence in the genesis of the cardiac symptoms. Trönnberg urged his colleagues not to spoil such patients by prescribing tonics and the like.

Tularemia.—Between 1931 and 1956 tularemia was reported in 814 human patients. Of these 85% came from one county where the disease is evidently endemic. The remaining 15% were from all over the country, but several of them came from an area adjoining the county in question. Here about 11% of the population showed a positive reaction to specific intracutaneous tests, so it is likely that in such an endemic area the disease occurs in an asymptomatic form. During 1952 and 1953 a lookout for this disease was kept at the bacteriological department of the General Hospital in Malmö by submitting serums received for the Widal test to routine examinations for tularemia agglutinins. They were never found, but in the summer of 1958 six patients (all women) with tularemia were admitted to this hospital. Dr. S. E. Björkman and coworkers (*Svenska Lakärtidningen,* Jan. 30, 1959) stated that suspicion of tularemia was raised by the combination of recurrent attacks of fever, pain in the muscles, and a universal erythema. The diagnosis was confirmed by a high agglutination titer. Four of the six patients presented a general rash or scattered hemorrhagic patches. In some the location of the rash suggested that stinging insects may have conveyed the infection from some animal host.

UNITED KINGDOM

Abortion on Television.—The subject of abortion was discussed on the British Broadcasting Corporation's television station by a psychiatrist, a gynecologist, and a forensic pathologist, all of whom were anonymous. Two girls, with their backs to the screen, opened the program with accounts of operations they had undergone at the hands of illegal abortionists. These operations were illustrated with anatomic diagrams and a close-up of a 3-month-old human fetus, which was shown to stress the point that at this period a miniature human being with a right to live is in existence. The pathologist presented the law on abortion. He told viewers that even when performed legally, with genuine medical indications, abortion could be dangerous and result in lifelong disability. The high incidence of criminal abortion in Britain (between 5,000 and 6,000 reported annually) and the septic conditions under which most abortions are performed were pointed out. The view was put forward that there was some benefit in legalizing abortion after rape, incest, rubella in early pregnancy, and in cases where the mother threatens suicide. The psychiatrist, however, disagreed with the last mentioned. This was an honest attempt on the part of the BBC to expose abortion as a major social evil. The program was mildly criticized by the *British Medical Journal*, which considered that the introduction was overdramatized and that a description of the complications of abortion and rubella in early pregnancy might alarm some of the viewers personally confronted with these problems, but the journal's comments were on the whole favorable.

Epstein's Brain.—Sir Jacob Epstein, the famous sculptor, made a bronze bust of Sir Russell Brain, former president of the Royal College of Physicians. The bust, presented by fellows of the college, was unveiled in the library after a dinner attended by Epstein, Brain, and the fellows. In a humorous speech Brain said "I am the speaking likeness of a bust by Epstein."

Forgotten Swab in the Abdomen.—In June, 1958, a woman was awarded $7,850 damages against a surgeon and a hospital authority for leaving a swab behind after an abdominal operation. The operation, which was an emergency procedure for repair of a ruptured uterus, was attended by excessive bleeding for which a large number of packs and swabs were used. It was estimated that 3.0 to 3.5 liters of blood were removed from the abdominal cavity. One of the swabs was inadvertently left in the abdomen. At a subsequent operation for intestinal obstruction the retained swab was found to be the cause. The judge held that the surgeon was negligent in not counting the swabs correctly and in leaving one in the patient's abdominal cavity. The case was taken to the court of appeal, where the judgment against the surgeon was reversed. He was exonerated from negligence and was in fact praised for saving the patient's life. It was held that without his speedy intervention the patient would have died from hemorrhage and that at the time the patient's condition was such that an exploration of the abdomen to look for swabs might have been fatal. The court, however, dismissed the appeal of the hospital authority, although it reduced the damages from $7,850 to $2,100. It held that there had been negligence in failing to count the swabs correctly and that the hospital was ultimately responsible for this. Operating room routine, it was argued, was designed to deal as efficiently with emergency operations as with planned operations.

Treatment of Cancer by Irradiation and Infusion of Stored Marrow.—The inevitable result of high-dosage irradiation for the treatment of cancer is bone marrow damage. This, and the unpleasant constitutional effects on the patient, has prevented the full use of radiation therapy in the treatment of metastatic tumors. Newton and co-workers described the use of stored autogenous bone marrow to combat the hematopoietic damage caused by irradiation in cancer patients (*Brit. M. J.* 1:531, 1959). The entire thorax of two selected patients with multiple pulmonary metastases was treated by means of the 2 Mv. Van de Graaff generator, delivering a dose of 3,000 r in two weeks. Two days before, during, and after irradiation the patients were given 20 mg. of prednisone and 100 mg. of vitamin K daily and 4 mg. of perphenazine three times a day. Before irradiation, with the patient under local anesthesia, bone marrow was aspirated from both iliac crests and the sternum and stored aseptically after dilution at −79 C. The volume of marrow obtained was 30 to 60 ml., containing 0.5 to 1.5 by 10^9 red blood cells. At the completion of the course of irradiation the bone marrow was thawed and injected intravenously. Within two to four weeks there was evidence of marrow regeneration in both patients. They tolerated the radiation well and experienced no immediate untoward side-effects directly attributable to it. The first patient had severe dyspnea and respiratory symptoms, but this was almost certainly due to the progress of the pulmonary metastases. The results showed that the entire thorax can be irradiated to 3,000 r in two weeks with no constitutional disturbance.

Immunization Against Helminthic Infection.—Although much experimental work has been published, the control of heminthic infection by vaccines has not hitherto been possible. A group of workers at the Glasgow Veterinary School has solved the problem of the helminthic infection of young cattle, called "husk," by administering a vaccine made from larvae attenuated by irradiation (*Proc. Roy. Soc. Med.* 51:743, 1958). The causative organism settles in the lung of calves, in which it causes high morbidity and mortality. Recovered cattle have a strong immunity to reinfection. The Glasgow workers found that some degree of immunity was afforded by intramuscular injections of whole worm vaccine, but that an oral vaccine of living but attenuated infective larvae was even more effective in preventing infection. The essential part of the technique is attenuation of the larvae by irradiation with roentgen rays before administration as a vaccine. The attenuated larvae migrate from the intestine to the lungs through the mesenteric lymph nodes, but here they die after provoking the necessary antigenic action. This technique has been explored with success in other helminthic infections of dogs and cattle, such as hookworm, cysticercosis, and nematodiasis.

Complications of Steroid Therapy.—Three cases of intestinal perforation after the administration of steroids to patients with rheumatoid arthritis were reported by Parker and Thomas (*Brit. M. J.* 1:540, 1959). One patient, who was treated with 30 mg. of prednisolone daily and then 150 mg. of cortisone daily, developed severe abdominal pain. Laparotomy revealed a recent 4-cm. perforation of the sigmoid colon. The perforation was repaired but the patient died from peritonitis. Another patient, under treatment with cortisone, died from the same condition after perforation of the cecum. The duodenum was perforated in the third patient, who was under treatment with cortisone. It was repaired but the patient died the following day. At autopsy the three patients were found to have widespread arteritis with fibrinoid necrosis. These patients had had no preexisting gastrointestinal disease. It was concluded that the intestinal perforation and arteritis were abnormal reactions to the cortisone.

Frozen Eye Bank.—Dr. B. Rycroft stated that eyes may soon be preserved almost indefinitely by deep-freeze storage. Corneal grafts have been thus preserved for many weeks, compared with one week's storage by older methods. The difficulty of corneal grafting at the moment is not only obtaining enough eyes but getting fresh material. Long-term preservation of eyes in an eye bank would help to solve this problem. Successful corneal grafting operations have risen from 10% 20 years ago to 60% today. In Britain the supply of grafting material has markedly increased since the passing of the Corneal Grafting Act of 1952, which awakened the public conscience to the needs of the blind. At the Corneo-Plastic Unit, East Grinstead, the number of eyes received now is six times what it was before the passing of the act. A mobile team is present at the unit ready to collect eyes from recently deceased persons. If deep-freeze storage proves successful, an eye bank could be built so that eyes for corneal grafting would always be available for the whole country. Rycroft said that the bequest of eyes after death is a direct contribution to the relief of blindness in this country. It is a gift of the highest order of humanity which anyone with normal eyes can easily make.

Fetal Tissue Bank.—Grafts of living cells exchanged between unrelated members of a species are destroyed after a short interval by an immune response of the host's lymphoreticular system—the so-called homograft reaction. Exceptions to this occur where the graft is "insulated," as in the cornea, or where the host's immune system is ineffective owing to immaturity, as in the fetus. Kay and Constandoulakis discussed the possibility of using fetal hematopoietic cells for transplantation after massive irradiation, either accidentally induced or from high-dosage radiotherapy (*Brit. M. J.* 1:575, 1959). The supply of human fetal tissue is severely limited, as during the first three months of pregnancy the fetus is small and seldom obtainable in a sterile and intact form. In the last three months, as the fetus is legally alive, the parents' consent must be obtained for disposal. Fetuses are also obtained as a result of terminations of pregnancy between 12 and 18 weeks. Twelve hours after delivery the cells of the fetus are no longer viable at room temperature, although if kept at 4 C cell death is appreciably delayed.

The authors organized a 24-hour service with the help of gynecologists in many London hospitals. The liver is the main source of fetal hematopoietic cells. No attempt was made to use spleen or bone marrow. The liver was dissected under sterile conditions and reduced to a cell suspension by pressing through a wire mesh, removing stroma, and breaking the tissue up into individual cells, which were cultured anaerobically and aerobically and stored at 4 C for 12 to 24 hours or at —79 C for longer periods. Short-term culture of a cell suspension can be made at this stage. Cells are preserved at —79 C for months or years. Using the technique of autoradiography the authors showed that desoxyribonucleic acid synthesis continues after freezing and thawing in 15% glycerol serum, but they did not know what proportion of stem cells survived. It costs less than $280 per year to store 5 liters of fetal tissue suspension, or about 3 by 10^{12} cells, by means of dry ice. Suspensions of these thawed cells can be given intravenously. By virtue of some extraordinary homing instinct these cells find their way to the appropriate site in the body, where they settle and multiply.

New Penicillin.—An important development in the antibiotic field was made by Batchelor and coworkers, of the microbiological unit of the Beecham Research Laboratories (*Nature* 183:257, 1959). They isolated from penicillin cultures 6-aminopenicillanic acid, from which a number of new penicillins may be obtained. It is hoped thus to produce penicillin O (allylmercapto-methyl penicillin) and cephalosporin N (α-amino-adipic penicillin), which do not cause reactions in penicillin-sensitive subjects. A new approach to the problem of penicillin resistance, particularly staphylococcic, is now a possibility. It is hoped that the new penicillin derivatives may prove active against such resistant organisms. Means may be found for increasing the activity of penicillin-type compounds against gram-negative bacteria. Some of the new penicillins are being tested against the organisms of whooping cough, scarlet fever, diphtheria, gas gangrene, tetanus, typhoid, meningitis, leprosy, and respiratory infections.

New Tranquilizer.—Stelazine (trifluoperazine hydrochloride), a fluorinated derivative of prochlorperazine, is a new tranquilizer. Macdonald and Watts used it to treat 50 patients with acute and chronic paranoid schizophrenia (*Brit. M. J.* 1:549, 1959). The dose given was 5 mg. daily for the first three days, thereafter increasing by 5 mg. daily at three-day intervals until side-effects were produced or until a satisfactory therapeutic result had been obtained. When symptoms had been controlled the dosage was reduced to a maintenance level on which the patients were free from side-effects and at which the therapeutic effect seemed maximal. The maximum dose was 45 mg. daily and the average maintenance dose was about 22.5 mg. daily. Trifluoperazine was given to 30 male chronic paranoid schizophrenics who had been hospitalized for at least two years, and to 20, admitted during the first attack of less than six months' duration, who had not had any previous treatment. The results were judged on the basis of the patients' capacity for adjustment to normal social surroundings. Of the 30 chronic cases 21 showed improvement ranging from suitable adjustment to life in the hospital community (12) to discharge from hospital to full employment (5). The results in the early cases were gratifying. Of the 20 acute cases 14 were able to return to full employment and 6 were well-adjusted socially within the hospital community. Trifluoperazine should prove a valuable addition to the drugs available for the treatment of schizophrenia.

Physiotherapy in Arthritis.—The value of physiotherapy in patients with arthritis was assessed by Hamilton and co-workers (*Brit. M. J.* 1:542, 1959). A trial was designed to study the effect of short-wave diathermy, infrared radiation, faradic stimulation, and paraffin wax baths on functional improvement in patients with rheumatoid arthritis or degenerative joint disease involving the hands or knees. These joints were chosen because they are the easiest in which to assess function accurately. Sixty-two patients were treated for a month with each form of therapy selected at random and the results compared with a period in which no physiotherapy was given. In addition, all patients were given analgesics and splinting as required, with active exercises after the treatment. Range of movement, power of extension of the joints, and the time taken to walk up and down standard stairs and over a measured distance were calculated for each patient before and after each treatment. No significant difference was found among any of the four treatments, nor was there evidence that any of the forms of physiotherapy gave significantly better results than no treatment, other than that with simple exercises, splinting, and analgesics. The authors concluded that the most useful physiotherapeutic measures for arthritics are those maintaining muscle power and joint movement by active exercise, good posture, and coordination of movement.

Fetal Blood Cells in Maternal Circulation.—It has recently been shown that the hemoglobin of adult red blood cells in a fixed smear can be eluted by an acid phosphate buffer, whereas the hemoglobin of fetal blood cells cannot. Using this test Zipursky and co-workers showed the presence of fetal blood cells in the blood of women just after delivery (*Lancet* 1:451, 1959). Smears of in vitro mixtures of fetal and adult blood were scanned for two minutes under the microscope. The number of fetal red blood cells counted varied from 2 in a dilution of 1:25,000 to 21 in a dilution of 1:1,000. When three adults were given 3.5 and 15 ml. of compatible placental blood intravenously, the fetal cells were demonstrated in the expected concentration in their blood. No fetal cells were found in male and nonpregnant female blood donors. The blood of 42 mothers, selected at random, and recently delivered, was examined on the second and sixth day post partum. In a two-minute scanning 1 to 16 fetal red blood cells were seen in 21% of the films. A count of 16 corresponds to 2 ml. of fetal blood in the maternal circulation. These observations suggest that the placental passage of fetal blood into the maternal circulation is common.

Atherosclerosis in Jamaicans.—Many workers have concluded that populations living on high-calorie high-fat diets have a higher mean serum cholesterol level and are more prone to develop ischemic heart disease than those living on simpler diets. Much of the evidence for this is circumstantial. Robertson recorded the incidence of atherosclerosis of the aorta at 500 autopsies in Jamaicans and has compared it with that in published series elsewhere in the world (*Lancet* 1:444, 1959). The population of the area studied was partly urban and partly rural, mostly Negro, with a few East Indian, Chinese, or Caucasian subjects. The predominantly Negro population in Jamaica was found to develop a degree of aortic atherosclerosis similar to that of a mixed population studied in New Orleans. The incidence of atherosclerosis runs parallel to that of ischemic heart disease in New Orleans, but not in Jamaica, where the incidence of myocardial infarction is much lower. Robertson therefore concluded that, since there is no constant relation between the incidence of atherosclerosis and that of coronary thrombosis, they are unlikely to have the same cause. He also stated that cerebral thrombosis, phlebothrombosis, and pulmonary embolism are comparatively uncommon in Jamaicans.

CORRESPONDENCE

CIRCULATING BLOOD VOLUME CHANGES

To the Editor:—It was distressing to read the article "Circulating Blood Volume Changes Incident to Major Orthopedic Surgery," by Powers and Hensley, in The Journal, Feb. 7, page 545. The major assumptions made in the article are that (1) any fluid administered into the vascular space remains there as is, in total; (2) iodinated albumin remains in the space to be measured, without leaving the circulation, for about 10 minutes; (3) no compensatory mechanisms are in progress during the surgical and anesthetic procedure, as well as during the mixing period; and (4) technically, a ±6% accuracy is obtainable in vivo.

None of these assumptions hold true when an intravascular volume is measured with plasma-bound elements. Phenomena of hemodilution and loss of fluid from the intravascular space are constantly in operation and are reflected in plasma volume changes. Whole blood and salt or glucose infusion have varying effects on the total volume (Thistlethwaite and others, *Surg. Gynec. & Obst.* 105:34-38 [July] 1957; Albert and others, *Anesth. & Analg.* 36:54-61 [Sept.-Oct.] 1957; Albert and others, United States Atomic Energy Commission Technical Information Service, no. AECU-3614 [March] 1957). Iodinated serum albumin leaves the intravascular space at a variable rate dependent on many factors (Gitlin, *Ann. New York Acad. Sc.* 70:122-136 [Aug. 30] 1957). Technically, to obtain a ±6% in vitro with iodinated albumin is very difficult due to the adherent properties of Risa to glassware (Reeve, *Ann. New York Acad. Sc.* 70:137-149 [Aug. 30] 1957).

The only correct method for measuring blood loss is measurement of total circulating red cell volume with red cells tagged with Cr^{51}. The technique is simple with no technical errors involved. Grave errors in judgment and measurement can be made by just measuring a total volume without estimating the cellular element, which is the only reliable method.

I do not contest the fact that considerable amounts of blood are lost during orthopedic surgery—far more than is estimated clinically; but I cannot agree with the method used and am sure that with proper measurements the facts and results would still be more striking. An additional measurement made 24 hours postoperatively would show the considerable blood loss that occurs from oozing.

S. N. Albert, M.D.
828 S. Wakefield St.
Arlington 4, Va.

To the Editor:—We believe that the validity of blood volume determinations with use of radioiodinated serum albumin is well established provided proper precautions are taken to reduce technical error. In fact, Hlad and Tanz (*J. Lab. & Clin. Med.* 52:289-298 [Aug.] 1958) reported a standard error of ±2% in vivo! That compensatory mechanisms are at work during anesthesia and operation is not questioned. Insofar as they do influence blood volume, it appears to be obvious that any blood volume determination, regardless of method, must reflect the changes they occur. Otherwise, the blood volume determinations would be without value.

The statement that the use of tagged cells is the only correct method, simple and without technical error, we believe, is open to debate. Adherence of chromium to glass has been reported (Small and Verloop, *J. Lab. & Clin. Med.* 47:255-260 [Feb.] 1956). Irregular mixing of radiochromate-labeled erythrocytes in the spleen has also been reported (Kraintz and others, abstracted, *Fed. Proc.* 17:89 [March] 1958). Pooling of erythrocytes probably occurs during operation. All of these factors can influence the accuracy of the method.

FALL-OUT AND LEUKEMIA

To the Editor:—In the United Kingdom foreign letter in The Journal, March 14, page 1234, is a note on fall-out and leukemia. The statement is made that I^{131} has never been linked with leukemia. The *New England Journal of Medicine* (260:76-77 [Jan. 8] 1959) contains an account of the sixth reported case of leukemia after use of I^{131} for hyperthyroidism. One of the six reports was in The Journal (165:1558-1559 [Nov. 23] 1957).

FALSE-POSITIVE REACTION FOR ACETONURIA

To the Editor:—While testing, with phenolsulfonphthalein (PSP), the renal function of a patient with well-regulated diabetes mellitus, a strongly positive reaction for acetonuria was noted. This false-positive reaction was noted with the conventional test for acetone, using sodium nitroprusside, as well as with Acetest tablets (Ames Co.) and acetone test powder (Denco). These color reactions could be reproduced with PSP diluted with water and are undoubtedly due to the fact that all three tests for acetone take place at an alkaline pH. The color produced by PSP is not exactly identical with that produced by acetone but is sufficiently similar to provide a source of error. The false-positive test result for acetone can readily be distinguished from true acetonuria by the failure of PSP to evaporate on boiling. The color could also be distinguished by spectroscopy, but this method of examination is not generally available. A positive ferric chloride test result for diacetic acid is not given by PSP.

MISCELLANY

PHYSICIAN WHO SERVED ON THE U. S. SUPREME COURT

James A. Tobey, Dr.P.H., LL.D.

Probably few physicians today are aware that their profession once contributed an eminent justice to the Supreme Court of the United States. He was Dr. Samuel Freeman Miller, a gentleman from Kentucky who was appointed to the Supreme Court in 1862 by President Lincoln. He served with distinction as an associate justice of this court for the next 28 years and on several occasions was considered for promotion to chief justice, although this honor went in 1864 to Salmon P. Chase, in 1874 to Morrison R. Waite, and in 1888 to Melville W. Fuller.

Dr. Miller was a lawyer as well as a physician, but until he studied medicine, and later law, he had had no formal education whatever. When he sat on the bench, however, he was regarded as an able and forceful exponent of the law, if not a scholarly one.

Born at Richmond, in the blue grass region of Kentucky, in 1816, Dr. Miller was only 20 years old when he entered the medical department of Transylvania University at Lexington. There he attended lectures for one year, leaving to teach school for a few months and returning to the medical department late in 1837 for less than six months, at which time he passed the necessary examinations and was awarded the degree of doctor of medicine early in 1838. With this sketchy foundation in medicine, in contrast to the eight or more years of college, medical school, internship, and residency required of modern American physicians, Dr. Miller set up in general practice in the mountain community of Barbourville, Ky.

Here he practiced medicine for the next 12 years, bleeding and purging his patients in accordance with the ideas of the times. He also became interested in a debating society, participated in politics as an antislavery Whig, and was appointed a local justice of the peace. These activities stimulated an interest in law. In those days the budding attorney, like many an aspiring medical student, usually served an apprenticeship with an older, established practitioner; but some, like Lincoln himself, merely read profusely in the commentaries of Blackstone, Story, and Kent and other available legal texts. Miller read so well that he was admitted to the bar in 1847.

Three years later he moved to Keokuk, Iowa, where he engaged in the practice of law. He also participated heartily in the activities of the newly formed Republican party. He was an ardent supporter of Abraham Lincoln, who in 1862 nominated Miller to the Supreme Court, an appointment which received the unanimous approval of the Senate. When Miller took his seat the Chief Justice was Roger B. Taney of Maryland, who had been appointed to this office in 1836 by President Jackson after the death of the great John Marshall, who had served for 34 years. Taney, incidentally, was a Roman Catholic, one of the first of his faith to hold this high office in the Republic.

During his nearly three decades on the bench of the Supreme Court, Mr. Justice Miller participated in some 5,000 cases and delivered the opinions for the court in 600 of them. One of these opinions, handed down in 1873 in the Slaughter House Cases (*16 Wall 36*), has a certain medical significance, since it held that an action by the state of Louisiana in granting a monopoly for the slaughtering of animals was a valid exercise of police power in the interests of the public health and not in contravention of the rights granted by the federal constitution.

Mr. Justice Miller, M.D., has been described as a tall, massive man, inclined to be domineering. Although self-educated, he was extremely well versed in the law. He died in 1890 at the age of 74. Although by no means the only physician who ever studied law and made a career of it, he was the only physician to sit on the Supreme Court of the United States, which in the course of 170 years has had 94 justices.

MEDICAL FILM REVIEWS

Portal Decompression: 16 mm., color, sound, showing time 29 minutes. Prepared by Charles G. Child, M.D., Boston. Produced in 1958 by Sturgis Grant Productions, New York, for and procurable on loan from E.R. Squibb and Sons, 745 Fifth Ave., New York 22.

This film is divided into two sections. In the first part animated diagrams depict the anatomy and physiology of the hepatic circulation and explain the etiological factors responsible for portal hypertension in terms of the clinical picture presented. In the second, a patient is introduced for whom portal decompression is indicated, and the surgical procedure for an end-to-side portacaval shunt is shown. The film demonstrates the value of audiovisual educational technique when proper coordination exists between the surgical team, the illustrator, and the photographic crew. The subject is presented in a style which is interesting and easy to understand. At all times the viewer knows what is being discussed or what is being done. An end-to-side portacaval shunt is demonstrated in a rather muscular and obese patient. This is a difficult photographic exposure to obtain; however, the anastomosis can be seen clearly. The emphasis placed on the importance of dilated lymph vessels, which may be injured during the course of dissection and thereby add to the morbidity or mortality, is particularly commendable. The author is also to be commended for the use of the term "esophagogastric varicosities" rather than merely esophageal varices. This film can be recommended to surgeons, medical students, and nurses.

Intracellular Recording in the Mammalian Heart: 16 mm., color, sound, showing time 21 minutes. Prepared by Theodore C. West, Ph.D., University of Washington. Produced in 1958 under a grant from the National Heart Institute, National Institutes of Health. Procurable on rental ($3.75) or purchase ($140.00) from The Film Center, University of Washington, Seattle 5.

This film presents a concise demonstration of the recording of membrane potentials of the various cardiac cells, in both the isolated atrium of the rabbit's heart and the dog's heart in situ. It acquaints the viewer briefly with the method of recording the potentials of individual cells with the floating glass electrode. The sequence showing depolarization and repolarization of cells in the sinoauricular node, in the atrium, and in the ventricle and the relation of the muscle to contraction are very well demonstrated. Changes induced by drugs (epinephrine and quinidine) and by variation of blood temperature are also shown. The photography and narration are excellent. The film has great teaching value, and it should be most welcome to all students of cardiac physiology and pharmacology.

Dynamics of Phagocytosis: The Interaction Between Group A Streptococci and Human Neutrophils in Vitro: 16 mm., black and white, sound, showing time 37 minutes. Prepared in 1958 by Armine T. Wilson, M.D., Wilmington, Del. Procurable on loan from Pfizer Laboratories, 630 Flushing Ave., Brooklyn 6, N. Y.

This film shows dynamically the process of phagocytosis, including chemotaxis, contact, ingestion, egestion, and leukotoxicity; and it depicts the events that occur when living streptococci and leukocytes interact in vitro. The phenomena of hemolysis, chemotaxis, and virulence are elucidated in relation to phagocytosis. The behavior of leukocytes and monocytes is shown. These and other interesting manifestations in the natural history of phagocytes are clearly and instructively illustrated. The film is well done and can be recommended for showing to medical students, biology students, physicians, and all interested in problems of immunity and susceptibility to disease.

Thursday's Child: 16 mm., color, sound, showing time 23 minutes. Produced in 1958 by and procurable on loan from Children's Medical Center, 4900 S. Lewis, Tulsa, Okla.

This film presents the diverse medical therapy programs available in the Children's Medical Center, including psychiatric service; child guidance clinic; school for the mentally retarded; training program for physicians, psychologists, and other medical personnel; and a 62-bed children's hospital providing a full program of rehabilitation for all types of children's disabilities. With the aid of a narrator and background music the viewer "tours" the medical center. The film deals with the story of the center's daily activities in caring for numerous physically and mentally disabled children. While it does not attempt to portray or teach any specific medical techniques, it is nevertheless interesting and should be of considerable help in stimulating the interest of the public and the medical profession in such activities.

Varicose Veins: 16 mm., color, sound, showing time 7 minutes. Produced in 1958 by Churchill Wexler Film Productions for and procurable on loan or purchase from the American Heart Association, 267 W. 25th St., New York 1.

The conditions leading to the development of varicose veins and methods of prevention and treatment are discussed in this film. Animation is used to illustrate the function of the blood vessels and valves related to understanding the problems of varicose veins. The onset and effects of relaxation of the vessels eventuating in varicose veins are depicted, and the anatomy of the veins is shown. The film points up the preventive measures, as well as what can be done when the condition develops. It is scientifically accurate and is highly recommended for adult audiences and also for family-living classes in high school and college.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Duodenal Ulcer Amongst Africans in Nairobi. Ashfaq Alam Khan. East African M. J. 35:679-684 (Dec.) 1958 [Nairobi].

The series of 28 patients with duodenal ulcer presented were admitted to the King George VI Hospital in Nairobi, Kenya, from August, 1957, to May, 1958. There were 20 males and 8 females. The criteria for diagnosis were: (1) a characteristic history; (2) a history of hematemesis or melena; and (3) the roentgenologic demonstration of an ulcer crater. The last factor was an essential prerequisite for inclusion in this study. The annual report published by the Kenya Medical Department shows the number of cases of duodenal ulcer in a rising curve, with a steep rise in 1956; similarly the figures for the King George VI Hospital show an upward trend. No particular liability or proneness to develop duodenal ulcer was observed in any tribe, nor was any tribe immune from it. All but 3 of the patients were between 18 and 40 years of age. All social groups were represented, and educational standards had no bearing on the incidence.

A dietary regimen, continued for 4 weeks, produced freedom from pain in 21 of the patients. All 10 who were reexamined 6 months later showed a healed ulcer on roentgenologic examination. Two others experienced relapses and had to be readmitted. One required gastroenterostomy. Four showed no improvement and refused operation. The author feels that medical treatment is adequate for the type of duodenal ulcer found in Africans, since the ulcer is generally small. One should resist the temptation to operate and try to persevere with repeated courses of medical treatment.

When people from the reserves come into the cities and take to a new mode of life, they are subjected to all the stresses and strains of the modern world. This may give rise to all sorts of anxiety states. In Africa, just as in any other part of the world, there are certain individuals who are ulcer prone, or have a large number of acid secreting glands in the stomach. The African reacts to the stress and strain of the pace of modern life in the same fashion as any other individual, and so is equally liable to get any of the stress diseases, of which duodenal ulcer is one.

The Role of Thoracotomy in the Differential Diagnosis of Pleural Effusion. J. M. Schless, H. N. Harrison and J. A. Wier. Ann. Int. Med. 50:11-33 (Jan.) 1959 [Lancaster, Pa.].

In an attempt to establish better criteria for the differential diagnosis of pleural effusion, the authors report on 63 patients with pleural disease who underwent open thoracotomy at the Fitzsimons Army Hospital in Denver between 1953 and 1956. The pleural involvement in all these patients either was due to tuberculosis or at some point in the course of the disease was seriously considered to be tuberculous pleuritis, or this condition could not be clinically excluded. The final diagnosis in 38 of the 63 patients was tuberculosis, and the remaining 25 patients were given a final diagnosis of nontuberculous pleuritis. The indications for thoracotomy were primarily diagnostic in 17 patients; in 14 patients the indications were both diagnostic and therapeutic; and in the remaining 32 patients thoracotomy was primarily a therapeutic procedure. Of the 63 patients, decortication was performed on 57, and 6 underwent open pleural biopsy in the course of a full exploratory thoracotomy. Pulmonary tissue was obtained by biopsy from 30 of the 63 patients.

All patients with the final diagnosis of tuberculosis had positive results from tuberculin tests. All patients with negative results from tuberculin tests were in the group with a final diagnosis of nontuberculous pleuritis. It is felt that a negative tuberculin test, done with properly prepared solutions and repeated 6 to 8 weeks after the onset of the effusion, effectively excludes tuberculosis as the cause of a given pleural effusion. However, positive results from tuberculin tests prove nothing as far as establishment of a diagnosis of tuberculosis is concerned, other than the fact that tuberculosis must be considered a possibility. The pleural fluid did not show consistent physical, chemical, or morphologic differences that could be relied upon to differentiate tuberculous from nontuberculous effusions. Only 7 (21%) of the 38 patients with a final diagnosis of tuberculosis had positive bacteriological findings on the pleural fluid aspirate. The

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

incidence of positive sputum and/or gastric aspirates (in only 14 [40%] of the 38 patients) was too low to be of differential diagnostic value in the negative sense.

Morphologic pleural changes established the presumptive diagnosis in 32 of the 38 patients. In 3 additional patients the diagnosis was established by the morphology of lesions discovered in the lung at the time of thoracotomy. In these 3 patients the diagnosis would never have been established had not full open thoracotomy with careful palpation of the lung been done. Thus, morphologic changes in the pleura and/or the lung established the diagnosis in 35 of the 38 patients. Morphologic findings in tissue obtained at open thoracotomy were, therefore, at least 92% reliable in this series in differentiating tuberculous from nontuberculous pleural effusions. Morphologic findings were unaffected even by prolonged chemotherapy in practically all patients, but the chances of bacteriological confirmation proved to be inversely proportional to the duration of preoperative chemotherapy. The specific drug regimens used did not seem to be important.

Follow-up information of from 6 months to 3½ years after discharge was available in 45 patients (71%). None of the patients with tuberculosis had relapsed, and in none of the patients who were cleared as having nontuberculous pleuritis had any evidence of tuberculosis developed since time of discharge. There seems to be a strong indication for a controlled study utilizing exploratory thoracotomy in pleural effusions of dubious causation. Except for a short period of preoperative drug coverage in all patients, antituberculous chemotherapy should be withheld in all patients who do not show morphologic or bacteriological changes compatible with tuberculosis. A long-term follow-up study on such a series of patients would seem to be of great value.

Whipple's Disease: Report of Four Cases, Including Two in Brothers, with Observations on Pathologic Physiology, Diagnosis, and Treatment. J. B. Gross, E. E. Wollaeger, W. G. Sauer and others. Gastroenterology 36:65-93 (Jan.) 1959 [Baltimore].

The authors report on 2 brothers, aged 62 and 63 years, and on 2 additional men, aged 44 and 50 years, with intestinal lipodystrophy (Whipple's disease), in all of whom the clinical and pathological pictures were typical. The cases of the 2 brothers constitute the second recorded occurrence of intestinal lipodystrophy in siblings. Some of the relatives of the 2 brothers had mental illness and diabetes mellitus, and the parents of the 4th patient also had diabetes mellitus and a "nervous condition." These findings suggest that diabetes mellitus and mental disease may be unusually prevalent among the relatives of persons with intestinal lipodystrophy. The pathological and clinical features of the 4 patients and of those reported on by other workers convinced the authors that intestinal lipodystrophy should be suspected in middle-aged white men with a chronic, wasting, steatorrheal diarrhea associated with antecedent migratory polyarthralgia. [To date the disease appears to have affected the white race exclusively, almost always men, and usually those of middle age.] Many patients had chronic cough, hives, chills and fever, ill-defined abdominal distress, and marked loss of weight. The patients usually appeared weak and wasted. Hyperpigmentation and hypotension were found in most of them, and peripheral lymphadenopathy was a common observation. Many patients exhibited an abdominal mass. The characteristic hematological findings were hypochromic anemia, increased erythrocyte sedimentation rate, and absence of macrocytosis. The concentration of mucoprotein in the serum was characteristically increased. Roentgenographically there was usually a deficiency pattern of the small intestine, and occasionally roentgenograms of the joints and spinal column revealed changes suggestive of rheumatoid arthritis.

Microscopic examination of the peripheral lymph nodes frequently revealed the presence of noncaseating granulomas suggestive of sarcoidosis. These nests of macrophages take the periodic acid–Schiff stain. Although the microscopic picture is not by itself specific, when it occurs in a patient with the characteristic clinical picture of intestinal lipodystrophy, the combination should serve to make one suspect more strongly this disease. The absolute diagnosis of intestinal lipodystrophy is a pathological one, resting on histological demonstration of macrophagocytosis of the tunica propria of the small intestine and mesenteric lymph nodes, and lipogranulomatosis of the mesenteric nodes. In the differential diagnosis of intestinal lipodystrophy clinically, one must consider sprue, adrenal cortical hypofunction (Addison's disease), Hodgkin's disease or other lymphoma, sarcoidosis, intra-abdominal malignancy, tuberculosis, regional enteritis, and chronic ulcerative colitis, as well as external pancreatic insufficiency.

The phenomenon of delayed excretion of water with regular nocturnal diuresis was observed in all 3 of the 4 patients in whom this phenomenon was tested. One of these 3 patients had a normal rate of absorption of heavy water in the fasting state. The diarrhea associated with intestinal lipodystrophy may or may not be bloody, but steatorrhea and azotorrhea are usually present, and the fecal fat and nitrogen losses may be similar to those characteristic of severe nontropical sprue and external pancreatic insufficiency.

Steroid therapy with cortisone, corticotropin (ACTH), and prednisone (Meticorten) proved disappointing in the 4 patients. The reports by other workers suggest that such treatment has usually been variable in effect and mainly of symptomatic help. One of the 4 patients had an apparently spontaneous remission, which included complete disappearance of the marked steatorrhea and which lasted almost 4 years preceding death.

Steroid Therapy in Pulmonary Fibroses. A. G. W. Whitfield. Brit. J. Dis. Chest 53:28-40 (Jan.) 1959 [London].

Of 35 patients with nontuberculous pulmonary fibroses and infiltrations treated with corticoids at the Queen Elizabeth Hospital in Birmingham, England, 6 had pulmonary sarcoidosis, 9 had irradiation damage of the lungs, 4 had diffuse interstitial fibrosis of the lungs (Hamman-Rich syndrome), and 16 had pulmonary infiltration occurring in collagen diseases, such as systemic lupus erythematosus (12), scleroderma (3), and polyarteritis nodosa (1). The results obtained with steroid therapy in these patients and the published reports by other workers showed that patients with pulmonary sarcoidosis in its earlier stages responded well to this therapy; it should be employed in all patients with respiratory symptoms or with progressive or persistent lung lesions. Permanent maintenance therapy is necessary to avoid relapse. Patients with irradiation damage to the lungs in the stage of pneumonitis appeared to respond to steroid therapy, and treatment for 3 months is suggested for all such patients. Patients with long-standing fibrosis did not respond, and corticoids are not considered to have any prophylactic value. The patients with the Hamman-Rich syndrome, except for one, were therapeutic failures; but since no other treatment can be offered, steroids must always be given a trial. The pleural lesions of systemic lupus erythematosus responded dramatically to steroid therapy. The interstitial pneumonitis occurring in this disease showed a less satisfactory response, but both pulmonary and pleural lesions should always be treated with corticoids. Permanent maintenance therapy is required to avoid relapse. The pulmonary lesions of scleroderma are unlikely to be improved by steroid therapy. The author's patient with pulmonary lesions associated with polyarteritis nodosa did not respond to steroid therapy, but 3 patients reported on by other workers did, and this therapy should be employed in every patient with polyarteritis nodosa.

Pulmonary Aspergillosis with Cavitation: Iodide Therapy Associated with an Unusual Electrolyte Disturbance. J. P. Utz, J. L. German, D. B. Louria and others. New England J. Med. 260:264-268 (Feb. 5) 1959 [Boston].

The authors report on a 47-year-old man and on a 63-year-old woman with an infection due to Aspergillus niger, associated with marked cavitation and abscess formation in previously damaged lung tissue. Carcinoma of the lung in the man and repeated attacks of pneumonia in the woman were the underlying diseases which presumably provided the appropriate environment for the superimposed fungous infection. Both patients were treated with a saturated solution of potassium iodide. The man received 30 Gm. daily for 2½ weeks, and the woman was given 24 Gm. daily for 3½ weeks; in addition, surgical drainage of the cavity was carried out in the second patient. Clearing of Aspergillus organisms from the sputum and lung tissue or abscess drainage material resulted from the treatment. Potassium iodide therapy was associated with a disturbance of the mental condition, manifested by exaggerated demands and disorientation in the woman. Hypopotassemia, with elevation of serum carbon dioxide content, and hyponatremia developed in both patients. In the woman, this bizarre electrolyte disturbance was associated with weight gain and with persistent excretion of sodium in a hypertonic urine, and these features suggest that the disturbance was due to inappropriate secretion of antidiuretic hormone, although the level of the serum electrolytes improved significantly in both patients when iodide therapy was discontinued. The woman also had hypocalcemia and hypophosphatemia for which no explanation could be given.

Pellagra in Ireland. E. A. Martin. J. Irish M. A. 44:11-15 (Jan.) 1959 [Dublin].

Three patients with pellagra were admitted to a private psychiatric hospital in Dublin. The first patient was a 42-year-old woman who had classical pellagra, showing, in sequence, diarrhea, dermatitis, and severe mental and neurological disturbance with stomatitis. The cause was probably a deficient diet of psychogenic origin. Death appears to have been due to unrecognized recurrence. The second patient was a 63-year-old woman who had acute confusional psychosis due to dieting, vomiting, and possibly malabsorption after gastroenterostomy. The first acute disturbance followed an operation. There was no dermatitis or glossitis. Within 3 days after onset of intensive oral and intramuscular vitamin therapy, diarrhea and incontinence ceased. The patient's mental state began to improve, and she took an interest in her surroundings. Within one week all confusion had disappeared. Her general health improved, and she put on weight. Oral vitamin therapy was continued. The third patient, a 49-year-old man, presented, in sequence, mental symptoms, a rash, and diarrhea. No dietary or intestinal cause was found. Sulfaguanidine, isoniazid, and streptomycin probably precipitated an acute confusional psychosis.

Since the patients were not poor, it is suggested that pellagra might be commoner in Ireland than is generally supposed. All 3 patients had passed through general hospitals, their condition undiagnosed. This emphasizes that the widespread view that pellagra is seen only in mental hospitals is untrue. Pellagra may be expected to occur chiefly in the elderly person living alone, the destitute, the mentally ill, the eccentric, the alcoholic, and those with some chronic gastrointestinal disease. Pellagra is caused by a deficiency of nicotinic acid. Often there is associated deficiency of other factors of the vitamin B complex—riboflavin and pyridoxine. The richest sources of nicotinic acid are meats, liver, kidney, heart, and yeast. Whole-wheat bread and cereals are good sources, but white bread, fish, milk, eggs, fruit, and vegetables have a poor content. Pellagra may develop secondary to infection or operation which may increase the need for vitamins, loss of appetite, enforced or prescribed dieting, vomiting, malabsorption due to rapid intestinal transit or steatorrhea, and alteration in intestinal flora. The foods rich in nicotinic acid are usually excluded in peptic ulcer diets. There is evidence that alterations in intestinal flora may be of importance. Bacterial biosynthesis of nicotinic acid in the intestine may produce up to 80% of the body requirements of this substance. Succinylsulfathiazole by its sterilizing action inhibits this production. Broad-spectrum antibiotics might be expected to have an even more potent effect.

The Treatment of Moderate and Severe Pneumococcal Pneumonia with Oral Phenoxymethyl Penicillin. J. T. Reeves, J. Garfield, N. Polasky and M. Hamburger. A. M. A. Arch. Int. Med. **103**:184-188 (Feb.) 1959 [Chicago].

In this report on the oral administration of phenoxymethyl penicillin (penicillin V) in the treatment of patients with pneumococcic pneumonia at the Cincinnati General Hospital, the authors add their experience of 1956-1957 to that of 1955-1956. In general, the results obtained during the second year on 68 patients confirmed those of the first year. Whereas during the first year's investigation several dosage schedules were explored, all patients during 1956-1957 were given an oral dose of 250 mg. of phenoxymethyl penicillin on admission and every 6 hours thereafter for from 3 to 14 days. Fifty-nine patients (87% of the 68) responded within 24 hours to the oral administration of phenoxymethyl penicillin with marked clinical improvement and prompt lysis of fever. The average duration of fever was 1.8 days, and no patient remained febrile beyond the 4th day.

The oral administration of phenoxymethyl penicillin has been shown to be an effective form of therapy for moderate and severe forms of pneumococcic penumonia. Oral therapy avoids the pain of injection, the expense and effort of sterilizing needles and syringes, and the dangers of needle-borne serum hepatitis. Although phenoxymethyl penicillin is not recommended for patients critically ill or having the purulent complications of pneumonia, it may be used with safety and confidence in the great majority of patients with pneumococcic pneumonia. The optimum dosage has not been established. Although patients treated by the authors were given 250 mg. every 6 hours, equivalent to approximately 1,600,000 units, patients treated by others received the same dose at 12-hour intervals, with similar results. Because an occasional patient fails to absorb phenoxymethyl penicillin as well as most subjects, the larger dose may be a safer one.

A Review of Fifty-One Cases of Multiple Myeloma: Emphasis on Pneumonia and Other Infections as Complications. H. Glenchur, H. H. Zinneman and W. H. Hall. A. M. A. Arch. Int. Med. **103**:173-183 (Feb.) 1959 [Chicago].

The recent renewed interest in the general problem of resistance to infections led to the discovery that patients with multiple myeloma are likewise susceptible to recurrent bacterial infections, particularly pneumococcic pneumonia. The authors present their observations on 51 patients with multiple myeloma, who were treated between 1947 and 1957 at the Minneapolis Veterans Administration Hospital. The diagnosis was established in each patient either by biopsy of bone marrow or accessible tumor or by autopsy and serum protein electrophoresis. The 51 patients with multiple myeloma represented 0.05% of 101,956 admissions. Thirty-four of the patients complained of bone pain usually localized to the back. Bone tenderness, the commonest physical finding, was found in 39 patients, mostly over the areas of pathological fractures or myelomatous involvement. Seventeen patients were found to have hepatomegaly at some time during their course. Nine patients had palpable tumors of either the skull, clavicle, sternum, rib, jaw, or pubis. Paraplegia was present in 5 patients. Forty-two of the patients are dead, 8 are living, and 1 has been lost to follow-up.

The authors were impressed with the high incidence of pneumonia. Twenty-eight patients experienced one or more episodes of pneumonia, exclusive of terminal pneumonia, during the course of their disease. A total of 76 episodes of pneumonia was experienced by these patients, averaging 2.7 bouts per patient. Electrophoresis of the serum of the 28 patients with pneumonia revealed only 1 patient with a normal protein pattern. Terminal pneumonia occurred in 17 of the patients. This reflects the increased susceptibility of patients with multiple myeloma to infection, the debilitated state, and the inexorable course of the disease. Seven of the 51 patients experienced bacteremia (14%). This incidence appears higher than chance would permit, and shows that the inability to produce effective antibodies leads to serious infections other than pneumococcic respiratory infections. Bacteria isolated from the blood included the Staphylococcus and Proteus organisms, Escherichia coli, and Neisseria catarrhalis. Twenty-nine of the patients had infections other than pneumonia, predominantly of the urinary tract. Repeated bacterial infections, especially pneumococcic pneumonia, should be emphasized as an important and often early complication of multiple myeloma. Antibiotics are effective unless their use is delayed.

Idiopathic Pulmonary Haemosiderosis in Adults and Adolescents. D. H. A. Boyd. Brit. J. Dis. Chest 53:41-51 (Jan.) 1959 [London].

Three cases of idiopathic pulmonary hemosiderosis are reported. Two occurred in men, aged 37 and 33 years, and one in a 19-year-old woman. Twenty-nine cases of this condition in persons over 16 years of age were collected from the literature. The more common clinical features were dyspnea, hemoptysis, and anemia; pyrexia, headache, hepatosplenomegaly, abdominal pain, and clubbing of fingers were less common. Natural remissions were frequent and in the author's 2 male patients lasted as long as 18 years and 5 years. The typical roentgenographic abnormality of miliary mottling, usually in the midzone and the lower zone, was almost always present at some stage of the disease. An acute attack may occur without roentgen-ray changes. As the causation of idiopathic pulmonary hemosiderosis remains unknown, effective therapy is lacking. The prognosis is serious. One of the author's 3 patients died, and 19 of the 29 patients reported by others were dead at the time of writing. The most recent work on the pathogenesis of the disease suggests that the elastic fibers of the small blood vessels of the lung are weakened by an increase in acid mucopolysaccharide. An analogy with senile elastosis and arachnodactyly has been drawn by other workers.

Staphylococcal Pneumonia. W. T. Couter. Illinois M. J. 115:57-61 (Feb.) 1959 [Chicago].

Hospital-acquired staphylococcic pneumonia represents a grave danger to life. The so-called "tame" or "hospital" Staphylococcus organism which causes this disease is present in nose and throat cultures of otherwise healthy hospital personnel. Eighty to 95% of physicians, nurses, and attendants harbor staphylococci in the anterior nares, and 60 to 75% of these organisms have been resistant to many antibiotics. The staphylococci may live for months in blankets or mattresses; the air itself acts as a medium of transference, and shaking out the blankets may disseminate the micro-organisms. The existence of such a large reservoir of pathogenic staphylococci renders likely the possibility of staphylococcic parasitization of the hospitalized patient. The widespread use of antibiotics for prophylactic reasons has been held partially responsible for the growing incidence of hospital-acquired staphylococcic disease. A patient entering the hospital with an antibiotic-sensitive strain of staphylococci generally maintains that strain throughout his hospital stay. In contrast, patients receiving either penicillin or a tetracycline tend to become carriers of the staphylococci predominant in that hospital. It seems evident that hospitalized patients, particularly those who receive antibiotics or steroids, can hardly escape from hemolytic staphylococcic colonization.

Staphylococcic pneumonia is a necrotizing process which makes treatment during the first hours mandatory. Sputum and sensitivity studies should be started as soon as a clinical diagnosis of pneumonia have been made, and energetic treatment with antistaphylococcic drugs should be instituted until the diagnosis has been confirmed. As certain strains of staphylococci tend to be constant and predominant in any one hospital, the choice of antibiotics might be determined by data already collected on previous cases by the hospital laboratory. Vigorous treatment by a battery of such antibiotics, to which other staphylococcic cultures have been sensitive, will not endanger the patient if the diagnosis should not be confirmed; in fact, such therapy may save the patient's life.

The Work of Breathing in Patients with Mitral Stenosis. R. Garbagni. Minerva med. 49:4832-4838 (Dec. 22) 1958 (In Italian) [Turin, Italy].

Energy cost of breathing was studied in 10 persons, 7 of whom (aged between 16 and 48 years) had mitral stenosis, and 3 had normal respiratory and cardiovascular functions. Dyspnea on exercise was present in all the patients, and dyspnea at rest in 2. The patients were unable to exert any excessive physical effort. Six patients had sinus rhythm, and one had total arrhythmia attributed to atrial fibrillation. The patients were free from symptoms of widespread cardiac decompensation. Roentgenograms showed an increased shadow either of the whole heart or of the right heart. The patients took 2 or 3 tests of hyperventilation at the breathing frequency of 30 or 40 a minute.

The energy cost of hyperventilation in persons of the control group increased proportionally with higher ventilatory volumes; it deviated from proportionality and became erratic in patients with mitral disease. Among the patients the lowest observed value of the cost of breathing oxygen per liter per minute was 0.53 cc. in a patient with very constricted mitral stenosis, associated with considerable limitation of chest movements caused by kyphoscoliosis. (Energy cost was stated, not in calories or other customary energy units, but in cubic centimeters of oxygen [1000 cc. O_2=4.825 Cal.].) The highest observed value of the cost of breathing oxygen per liter per minute was 12 cc. in a patient with mitral stenosis accompanied by pulmonary arterial hypertension. Use of the spirometer showed normal ventilatory values in 2 patients and decreased values, ranging from 29 to 41% of the theoretical normal values, in the remaining patients.

Although the scatter of the points on a two-dimensional plane, plotting the values of the energy cost of breathing, was more dispersed for patients with mitral stenosis than for the control group, yet the area containing these scatter points, either of the patients or of the control group, occupied approximately the same position in the diagram. The only exception was the patient with pulmonary arterial hypertension, who exhibited high values of the energy cost of breathing. Similarly, no direct relationship between the increased work of breathing and the degree of severity of a possible cardiovascular disorder could be postulated.

SURGERY

Total Cervical-Spine Fusion for Neck Paralysis.

J. Perry and V. L. Nickel. J. Bone & Joint Surg. 41A:37-60 (Jan.) 1959 [Boston].

The authors report on 100 patients with severe paralysis of the cervical muscles with residual instability of the head, who were studied at the Rancho Los Amigos Poliomyelitis Respiratory Center in Downey, Calif.; their object was to formulate a systemic therapeutic plan for those who had regained considerable use of their extremities and now needed a stable head and neck for maximum activity. Close examination of these patients revealed that the muscles of the neck form 4 functional groups, namely, flexors and extensors acting on the head, which were designated "capital flexors" and "capital extensors," and flexors and extensors acting only on the cervical spine, with motion centered in the lower cervical spine, for which the terms "cervical flexors" and "cervical extensors" were coined. Paralysis of the muscles of the neck may prevent the patient's taking advantage of the function that is present in his extremities. Paralysis of the capital extensors may greatly embarrass or completely prevent swallowing and speech by allowing the head to fall into extreme flexion.

Twenty-two fusions of the cervical spine, 10 of which included the skull, were performed at the Rancho Los Amigos Hospital during the past 2½ years. Results showed that total cervical spine fusion is an effective way of replacing the stability essential for general activity, and this fusion must include the occiput if the capital extensors are weak. A halo fixed to the cranium with screws and fastened to an adjustable countertraction device, which has been fixed to the body cast, proved to be a successful means of stabilizing the head and neck for fusion in a predetermined position. With the use of mechanical respiratory aid, the presence of respiratory paralysis is no longer a deterrent to safe major reconstructive surgery.

A Resectable Form of Multiple Mesothelioma.

M. S. Harris, M. M. Hyman and D. B. Nevius. Dis. Chest. 35:127-133 (Feb.) 1959 [Chicago].

The authors report on 2 women, aged 43 and 37 years, and a 51-year-old man with multiple mesothelioma of the pleura, for which these patients were operated on. Their cases had certain gross and microscopic characteristics in common. At surgical intervention it was noted that, although the tumors over the parietal surface were quite hard and appeared to involve the underlying soft tissues, bone itself and deep structures were not invaded, and the tumors were movable. The diffusely spread masses could be stripped from the chest wall along with the pleura without resorting to rib resection. Although the frozen section made in the course of the surgical intervention was reported as adenocarcinoma, it was decided, in the case of the first woman, to rely on clinical judgment and to proceed with radical resection. This patient is living and well more than 5 years after the operation. In the case of the man, the frozen section was reported as "papillary adenocarcinoma of the pleura, possibly metastatic, possibly mesothelioma." Because of this report, the situation was deemed hopeless, and the chest was closed. The patient was reoperated on 6 months later, but complete removal of all visible tumor was no longer possible. The pathological diagnosis on the permanent paraffin sections was "mesothelioma of the pleura." The patient died 7 months later, with widespread involvement of the chest wall, mediastinum, and pericardium. In the case of the second woman, a radical pleuropneumonectomy was performed, although the frozen section was reported as adenocarcinoma. The patient is doing well 2 years after the surgical intervention.

The point is raised that the resemblance to adenocarcinoma in frozen sections might lead the surgeon to abandon the surgical intervention in the belief that a hopeless situation exists. It is suggested that the pattern of clinical course, chest roentgenogram findings, and gross findings at surgical intervention should raise the question of a resectable mesothelioma of the pleura, despite a contrary pathological report based on a frozen section. Later, close studies of permanent paraffin sections of the 3 cases in this series were interpreted as mesothelioma because of a differentiation not possible on the frozen-tissue study. These observations emphasize the unreliability of the frozen section in diagnosing mesothelioma of the pleura and the need of clinical awareness of its deceptive appearance both microscopically and grossly.

Lower Esophageal Rings: Report of 14 Cases. J. R. Spencer, R. W. Hammer and W. H. Wierman. Am. Surgeon 25:20-24 (Jan.) 1959 [Baltimore].

The authors direct attention to an abnormality of the distal part of the esophagus, which has been designated as "contractile ring of the lower esophagus" or as "Schatzki ring." They detected it in 14 patients studied in the x-ray department of the Presbyterian Hospital, Denver, in an 18-month period from March, 1956, to September, 1957. Data on these 14 patients are summarized. Only 4 presented the characteristic symptom of intermittent dysphagia; in each of these 4 patients the size of the ring was 13 mm. or less. In 7 patients an esophageal hiatus hernia was demonstrable roentgenologically in association with the ring. Failure to clearly demonstrate such a hernia in the remaining 7 patients does not, however, exclude its presence. Only 2 patients were under 50 years of age, and both of these were without dysphagia. Of the 4 patients with dysphagia, 3 were treated by esophageal dilatation or dietary instructions. The 4th patient was subjected to surgical exploration because of poor response to surgical measures.

The distal part of the esophagus was mobilized, there being no evidence of an esophageal hiatus hernia. Palpation of the esophagus revealed no abnormality except possibly some increased thickening of the wall at the level approximately 4 to 6 cm. above the diaphragm. The esophagus was opened longitudinally at this level. An exploring finger was then inserted into the esophageal lumen and was passed with ease distally into the stomach and proximally. The esophagus was closed in 2 layers without a definitive surgical procedure being performed. The dysphagia disappeared after this exploratory procedure. It is probable that myotomy was performed inadvertently.

The anatomic substrate of the roentgenographic entity of "contractile ring of the lower esophagus" has not been clearly demonstrated, but limited observations suggest either an overactivity or hypertrophy of the inferior esophageal sphincter. The anatomic findings in the few surgically treated patients were conflicting. Only the smaller rings (13 mm. or less in diameter) cause dysphagia; the larger rings are asymptomatic. Conservative treatment provides symptomatic relief in most patients.

Virilizing Tumor of the Adrenal Gland with Pigmentation and Arterial Hypertension Successfully Treated by Surgical Exeresis. P. Mozziconacci, C. Dubost, J. L'Hirondel and others. Semaine hôp. Paris 34:3173-3179 (Dec. 24) 1958 (In French) [Paris].

The authors report on a girl, 2 years of age, with a precocious puberty syndrome. The case was unusual in that manifestations were very early, and there was abnormal pigmentation and arterial hypertension, which intervention caused to disappear. Body hair was heavy and black; external genital organs were quite developed; acne was present on face and back; there was considerable muscular force; the voice was deep and harsh; and bone development was equal to that of a child of 6 years. Androgenic hyperactivity originated in the adrenal gland. Absence of response to corticotropin (ACTH) permitted determining that hyperplasia was not present, and, therefore, a tumor was sought. Much elimination of fraction B of the 17-ketosteroids confirmed the impression. Roentgenologic examination showed a tumor, the size of a grapefruit, which lowered the right kidney. It was removed and found to be a corticoadrenal adenoma. After the operation precautions were taken to avoid a sudden drop in the patient's arterial pressure. Adrenal insufficiency was supplemented with hydrocortisone, cortisone, and desoxycorticosterone. The left adrenal gland was reactivated with ACTH. Fifteen months after intervention the clinical transformation was complete. The child's hair became blond, the skin became fine, and the height and weight increased in normal proportion for age.

The authors suggest that the problem of distinguishing a tumor from hyperplasia of the adrenal gland is partly settled by the criterion of time of appearance of clinical signs. In virilizing tumor, signs are present very early, in this case at birth. In hyperplasia, clinical signs do not appear for several months and frequently not for several years. Absence of response to ACTH and much urinary elimination of dehydroepiandrosterone confirmed the probability of tumor in this case. Hyperpigmentation is generally attributed to excess functioning of the hypophysis, which is no longer checked by cortical secretion. Hypertension in the presence of adrenal gland tumor in a child may be the result of an endocrine mechanism.

Crohn's Disease. A. V. Pollock. Brit. J. Surg. 46:193-206 (Nov.) 1958 [Bristol, England].

In the present study, a group of 34 patients, first reported in 1950, has been reexamined, and the series extended by the addition of all patients with regional ileitis (Crohn's disease) admitted to the Leeds General Infirmary from 1950 to 1956. In all, the cases of 108 patients (48 male and 60 female), ranging in age from 4 to 69 years at time of operation, were reviewed. The author prefers the term "Crohn's disease" because he feels that even the least specific of the noneponymous names is too restrictive to describe a disease which sometimes shows itself in a diffuse and not a regional inflammation. He excluded from this series all patients with lesions not conforming to a provisional definition of Crohn's disease as "a chronic inflammatory disease of the gastrointestinal tract of unknown etiology, usually manifesting itself in the form of localized thickening of the intestinal wall, with a strong tendency to recurrence which may be more diffuse than the original lesion." This definition excludes cases of solitary ulcers of the jejunum or ileum, intestinal tuberculosis, chronic ulcerative colitis, chronic localized diverticulitis, and intestinal actinomycosis.

In discussing possible relations to other diseases, the author gives particular attention to ulcerative colitis, pointing out that opinions are sharply divided. He presents brief histories of 7 patients in this series, in whom a diagnosis of ulcerative colitis was entertained at some time during the course of the disease. There is evidence that in patients with classical Crohn's disease of the small intestine a diffuse colitis, generally right-sided and resembling nonspecific ulcerative colitis, may develop, and these patients have been considered to be primarily cases of Crohn's disease. When obstruction or fistula complicates Crohn's disease, surgical treatment is indicated. Nothing was found to indicate the superiority of resection in 1 or 2 stages, short-circuiting, or short-circuiting with exclusion of the diseased segment.

Fifty-two of the patients in this series have been followed for more than 5 years, and 30 for more than 10 years. The recurrence rate in patients who had symptoms for more than 2 years before operation, and have been followed for more than 5 years subsequently, was 65%. When the history before operation was less than one month, nearly all the patients recovered permanently, only 12% having suffered a recurrence. When the history before operation was between 1 month and 2 years, 22% of the patients followed for more than 5 years developed a recurrence. In two-thirds of the recurrences, symptoms of recurrence commenced within a year of operation. Once the disease has recurred, it is unlikely to be brought permanently under control by medical or surgical means.

Congenital Coronary Arteriovenous Aneurysm: Clinical, Angiocardiographic and Physiologic Findings on Three Patients with Successful Surgical Correction. B. M. Gasul, E. H. Fell, M. Moreano and M. Weinberg Jr. A. M. A. Arch. Surg. 78:203-205 (Feb.) 1959 [Chicago].

The authors report on a 7-month-old male infant and on 2 boys, aged 5 and 9 years, with congenital coronary arteriovenous aneurysm draining into the right ventricle, in whom the aneurysmally dilated right coronary artery was successfully ligated and the aneurysm resected. The correct preoperative diagnosis was made in these patients by correlating the clinical findings with those of venous angiocardiography, retrograde aortography, and cardiac catheterization. Corrective surgical treatment is feasible for patients with this rare malformation.

The Surgical Treatment of Marginal Ulcer. J. M. Beal. Am. Surgeon 25:1-7 (Jan.) 1959 [Baltimore].

Two hundred four patients in whom a diagnosis of marginal ulceration was established were admitted to the New York Hospital from 1932 through 1957. Anastomotic ulceration followed gastrojejunostomy in 151 patients, and it was a sequel of partial gastrectomy in 53. The interval between the primary operation and the appearance of marginal ulceration varied from 2 weeks to 29 years. The peak incidence of secondary ulceration after both partial gastrectomy and gastrojejunostomy was within 1 year of the primary procedure, but in a significant number of patients who had undergone gastrojejunostomy stomal ulceration occurred more than 10 years later.

In 44 of the 151 patients who had undergone gastrojejunostomy, the marginal ulceration was managed without operation. The remaining 107 patients were subjected to a total of 324 surgical procedures. Dismantling of the anastomosis and partial gastrectomy were performed in 62 patients. A second partial gastrectomy was undertaken in 4 of this group for recurrent ulceration, and an additional patient had a transthoracic vagotomy. In 29 patients dismantling of the gastrojejunal anastomosis alone was performed. Resection was performed later in 16 of this group. Eight patients were treated by vagotomy. Later partial gastrectomy was performed in 3 of these. Miscellaneous procedures were employed in 8 patients. Four patients were subjected to revision of the gastrojejunal anastomosis. One patient had a bleeding vessel ligated through a gastrostomy; a gastrojejunocolic fistula was closed in one. The fistula recurred later and was treated by partial gastrectomy. Pyloric exclusion was accomplished in one patient. Recurrent ulceration appeared, and relief of symptoms was obtained by excision of the gastric antrum one year later. Jejunojejunostomy was performed in one patient. Six deaths occurred in the postoperative period—1 after dismantling and resection, 4 after simple dismantling, and 1 after vagotomy. Analysis of the results of treatment of marginal ulcer after gastrojejunostomy demonstrated that there are definite hazards whether conservative or operative treatment is employed. There were 8 postoperative deaths and 5 deaths caused by ulcer in the 107 surgically treated patients, a total mortality of 12.1%. There were 5 deaths from ulcer among the 44 patients treated without operation (11.3% mortality). However, only 4 of this latter group remained free of ulcer symptoms, whereas in the group of patients who were treated by surgical means after the appearance of stomal ulceration, 47 are considered well.

Nineteen of the 53 patients in whom stomal ulceration developed after partial gastrectomy received conservative management. The 34 patients who were treated surgically had a total of 104 operations. A higher resection was undertaken in 14 patients, with one postoperative death. Seventeen patients were subjected to vagotomy; in 13 a transthoracic approach was employed, and in 4 the vagus nerves were divided by subdiaphragmatic exposure. Miscellaneous procedures were carried out in 3 patients. Of the 19 who were treated by conservative methods, only 2 are free of ulcer symptoms, and 1 has died of complications from ulcer. Of the 34 patients treated by surgical procedures, 14 have remained well for 5 years or longer. Seven patients have been free of ulcer for less than 5 years. Three died from operative intervention in this group of 34 patients. Although the mortality rate was not significantly different for surgical and nonsurgical management, relief from recurrent ulceration was significantly greater in the surgically treated patients.

Dumping Syndrome: Recent Changes in Concept of this Common, Distressing, and Hence Important Postgastrectomy Development. J. W. Butin. J. Kansas M. Soc. 60:1-10 (Jan.) 1959 [Topeka].

Gastric surgery which bypasses or sacrifices the pylorus produces uncomfortable symptoms shortly after meals, called the dumping syndrome. These symptoms may be classified according to probable mechanisms of production as (1) mechanical and (2) vasomotor. Mechanical symptoms are characterized by abdominal fulness, nausea, and, at times, crampy abdominal pain followed by diarrhea. Vasomotor symptoms are characterized by perspiration and feeling of warmth, faintness, and tachycardia. In order to determine the true significance of the dumping symptoms, the author studied 94 consecutive patients who had undergone gastrectomy for benign disease at the Wichita (Kan.) Clinic between 1948 and 1955. The Billroth II operation had been carried out on 41 of the 94 patients, 25 of whom demonstrated dumping symptoms postoperatively; Billroth I operation had been performed on 14 of the 94, 7 of whom showed dumping symptoms after the operation, and the Hofmeister modification of Polya's operation had been carried out on 21, 13 of whom showed dumping symptoms after the operation. The type of operation was not known in 9 of the 94 patients with dumping symptoms. Thus, dumping symptoms were clearly recorded in 45 of the 94 patients.

Analysis of these patients revealed that neither the type of operation nor the amount of stomach resected seemed to reflect a relationship to the dumping syndrome. There is no means by which one can know preoperatively which patient will develop dumping symptoms, nor is there a way by which they can be effectively prevented by modification of the surgical procedure itself. Questionnaires were sent to the first 52 patients whose records contained possible complaints indicating existence of the syndrome. Thirty-six of these patients returned the questionnaires, complaining chiefly of the mechanical symptoms which occurred 30 minutes after eating; they were of the opinion that excessive food intake or excessive exercise after meals would produce these symptoms. Most common offending foods were dairy products, sweets, and any liquids taken with meals. Twenty-three of the 36 patients still had dumping symptoms at the time the questionnaire was filled out from 1 to 5 years after gastrectomy, and 18 of these patients indicated that the symptoms occurred often enough to be considered significant.

The most attractive theories of etiology of the syndrome are based on the relationship of osmotic pressures within the jejunum to those within the blood. The osmotic pressures can be increased by ingestion of foods which are hypertonic, especially if sufficient liquid is consumed to dissolve them. Such osmotic energy can be dispersed by vomiting, by diarrhea, or by reclining of the patient which produces a reflux of the meal into the gastric remnant. However, unless such dispersal of osmotic pressures occurs, a sudden shift of extracellular fluid from the blood to the jejunum results, which equalizes osmotic relationships between the 2 areas. The resultant decrease in blood volume is accompanied in certain individuals by a marked peripheral vasodilatation which results in pooling of blood away from the central areas, such as the heart and brain. The vast amount of fluid entering the jejunum itself produces distention and the mechanical phase of symptomatology, whereas the vasomotor symptoms are mediated through the autonomic nervous system, discharges of which seem to be initiated by acute changes in the circulating blood volume.

Satisfactory medical treatment of the dumping syndrome is based on dietary manipulation. Sweets, fluids, and dairy products are avoided with meals. Rest in the reclining position is advised after an unavoidably large meal. Small frequent feedings are preferable, especially in the early postoperative period. It is felt that apparent spontaneous improvement of the patient with the postgastrectomy syndrome usually reflects a process of self-education. The physician who understands the physiological mechanisms of this postgastrectomy syndrome can often lead his patients quickly to a remission of these troublesome symptoms.

Hirschsprung's Disease: Nine Years' Experience at the Hospital for Sick Children, Toronto. B. Langer and S. Thomson. Canad. J. Surg. 2:123-130 (Jan.) 1959 [Toronto].

While congenital megacolon (Hirschsprung's disease) has been recognized as a disease entity for well over 70 years, it is only in the past 15 years that a satisfactory concept of its etiology and treatment evolved. The authors review the development of the present concept of this disease, pointing out that it was not until 1948 that Swenson correlated the pathological findings with x-ray observations and, in addition, carried out motility studies. The primary defect is a congenital maldevelopment of the innervation to the undilated segment of the intestine, which is recognizable on pathological examination by absence or scarcity of ganglion cells in the myenteric plexus, and is usually accompanied by an increase in the number of nonmyelinated nerve fibers. Swenson stated that this defect in innervation was responsible for the failure of this part of the intestine to expand or transmit peristaltic waves in a normal fashion, thus producing a physiological obstruction with resulting proximal dilatation and hypertrophy. With recognition of the aganglionic segment as the diseased part of the intestine, Swenson also developed a method of excising it as far as the anus and of anastomosing ganglion-containing intestine to anus by a pull-through procedure. This operation has now replaced all other procedures in the treatment of the disease.

The authors report studies on 58 children with Hirschsprung's disease observed at the Hospital for Sick Children at the University of Toronto from 1949 to 1958. The diagnosis was verified in most of these children on the basis of pathological material. As in other reported series, there was a marked predominance of males (46 boys and 12 girls). The age at which symptoms brought these children to the hospital for the first time varied from 1 day to 6 years. The problem of diagnosis in the newborn infant is reflected in the fact that, of the 20 children seen during the first week of life, the correct diagnosis was made within a week of admission in only 5. Of the remaining 15, the condition of 5 was recognized at postmortem examination, and that of 10 was diagnosed after a period varying from 2 weeks to 6½ years. The provisional diagnoses included unspecified intestinal obstruction, meconium ileus, congenital anal stenosis, gastroenteritis, and pyloric stenosis. There were 20 deaths, but only 8 were postoperative deaths; 4 of these 8 children were moribund at the time of operation. Twelve of the 13 patients who were not subjected to a suitable operation died. With a better understanding of Hirschsprung's disease, the diagnosis is being made with greater frequency and earlier in the course of the disease. The main adjuncts to clinical diagnosis are special x-ray methods of visualizing the colon and pathological examination by rectal biopsy.

Surgical treatment is advisable in all cases. At the authors' hospital the first pull-through procedure was done in 1949, and since then a total of 22 patients with Hirschsprung's disease proved by pathological examination have undergone operation. The age at time of operation varied from 1 month to 11 years. In the early 1950's the pull-through operation was a primary procedure, without preliminary colostomy, at any age from one month on, if the patient's condition permitted. During recent years the practice has been to perform a primary pull-through operation only on older children (over 2 years of age) who are in good condition. On all others a preliminary defunctioning colostomy is done above the aganglionic segment, the definite operation being delayed until the infants reach at least 20 to 25 lb. in weight.

NEUROLOGY & PSYCHIATRY

Attempt at a Classification of Postoperative Deliriums: A Physiopathological and Therapeutic Synthesis. P. Chalnot, P. Michon, J. Sommelet and others. Semaine hôp. Paris 35:8-12 (Jan. 4) 1959 (In French) [Paris].

The authors differentiate between the postoperative delirium associated with alcoholism (delirium tremens), which is usually related to alcohol withdrawal and possibly to hyperkalemia, and the postoperative deliriums which are essentially connected with hydroelectrolytic disorders occurring in nonalcoholic subjects. Study was carried out by means of clinical data, biological values, and determination of neuromuscular excitability in 18 patients. In postoperative delirium tremens, a widespread neuromuscular hyperexcitability, in which muscle is more excitable than nerve, was consistently found. It is probable that hyperkalemia with cellular hyperhydration constitutes the most important biological fact in postoperative delirium tremens.

The varieties of postoperative delirium which are connected with metabolic hydroelectrolytic disturbances are as follows: delirium with extracellular dehydration, hypokalemia, and cellular sodium intoxication; delirium with extracellular dehydration, increased osmotic pressure, and excessive electrolytes in the blood; delirium with cellular hyperhydration and water intoxication, which is usually the result of an excessive and badly directed treatment; delirium with multiple electrolytic losses and preponderant sodium loss; delirium with alkalosis; and delirium with multiple deficiencies. These distinctions between types of delirium allow use of an adapted therapy. Any therapy not explicitly directed risks being not only inefficacious but also dangerous. True postoperative delirium tremens reacts well to the anesthetic steroid, hydroxydione sodium succinate (Viadril). Correct hydration, sufficient caloric support, and administration of strong doses of vitamin B_1 and magnesium sulfate are associated with this therapy. For electrolytic disturbances the authors use a combined preparation of levulose, insulin, and potassium, or hypertonic salt solutes and desoxycorticosterone acetate, or a reduced water intake according to the case.

There is always the possibility that different varieties of postoperative delirium will succeed each other in the same individual. Therefore, a daily water balance and often a series of apparently contrasting therapies are necessary. Research should continue along the lines of clinical study, evaluation of electrolytes in the serum, water balance, and determination of neuromuscular excitability.

Central Pontine Myelinolysis: A Hitherto Undescribed Disease Occurring in Alcoholic and Malnourished Patients. R. D. Adams, M. Victor and E. L. Mancall. A. M. A. Arch. Neurol. & Psychiat. 81:154-172 (Feb.) 1959 [Chicago].

The authors report on 3 alcoholic patients (2 men, aged 38 and 43 years, and a 29-year-old woman) and on a severely malnourished 53-year-old woman with a single pathological entity for which the term "central pontine myelonolysis" was chosen. These patients had been admitted to the Boston City Hospital where they died. Autopsy revealed a single, sharply outlined focus of myelin destruction, which was localized in the rostral part of the pons and indiscriminately affected all the fiber tracts. The axis cylinders and nerve cells were largely spared, and there were no inflammatory or vascular changes. The process probably began in the central portion of the pons and spread in a centrifugal manner, disposing itself symmetrically about the midline. In the 38-year-old man and in the 29-year-old woman with the largest lesions, the disease had manifested itself clinically by a pseudobulbar palsy and rapidly evolving flaccid quadriplegia, with weakness of the face and tongue and an inability to speak and swallow, leading to death in about 13 and 26 days. In the other 2 patients there were no symptoms referable to the lesions, presumably because of their small size. The condition did not resemble vascular diseases of the brain stem, Wernicke's superior hemorrhagic polioencephalitis, degeneration of the corpus callosum (Marchiafava-Bignami's disease), multiple sclerosis and related disorders. No reference to a disease of the described type has been found in the medical literature of the past 75 years.

The causation of central potine myelinolysis is unknown. Occurring on a background of alcoholism and malnutrition, the nature and location of the disease favor either an exogenous or an endogenous intoxication, or a deficiency of some substance essential to the metabolism of nerve tissue. This hitherto undescribed disease deserves a special name because of its unique clinical and pathological features; it has been designated as central pontine myelinolysis because this term denotes both the specific anatomic localization of this disease and the remarkable unsystematic dissolution of medullated fibers. This description seems preferable to pontine demyelination for 2 reasons. First, demyelination appears to represent only one phase in the course of this disease. In the central part of each lesion, what had begun as a demyelinative process eventually resulted in a destruction of all elements, even the supporting tissues, with resulting cavitation. Second, the term "demyelination" has been applied to a diversity of diseases, usually connoting multiple sclerosis and related disorders, and therefore has come to lack precision.

GYNECOLOGY & OBSTETRICS

Mesenchymal Sarcoma of the Uterus. W. B. Ober and H. M. M. Tovell. Am. J. Obst. & Gynec. 77:246-268 (Feb.) 1959 [St. Louis].

One of the authors had suggested in a previous study a four-group classification of uterine sarcoma: (1) leiomyosarcoma, (2) mesenchymal sarcoma, (3) blood vessel sarcoma, and (4) lmyphoma. In this paper the authors excluded all leiomyosarcomas, the most frequent form of uterine sarcoma. The total of 29 cases, on which this report is based, included, in addition to 26 cases of mesenchymal uterine sarcoma, 1 case of hemangiosarcoma and 2 of lymphoma. The 26 cases of mesenchymal sarcoma, of which 25 were followed up, are classified into 4 categories according to whether their cellular components are pure, mixed, homologous, or heterologous in origin. "Pure" sarcoma signifies one composed of one cell type only; "mixed," composed of more than one cell type; "homologous," containing tissue elements indigenous to the uterus; "heterologous," containing tissue elements foreign to the uterus. Irrespective of cell composition, all members of this family of tumors can be traced to an origin from derivatives of the mesenchyme of the urogenital ridge, specifically that derived from and surrounding the epithelium of the Müllerian duct.

The pure homologous sarcomas occur in younger women, often premenopausal; they grow slowly, metastasize late, if at all, and pursue an indolent clinical course. Total hysterectomy followed by radiation therapy, as indicated, affords a reasonable prognosis for a long-term survival. The pure and the mixed sarcomas, whether homologous or heterologous, occur in older women, usually postmenopausal; they grow rapidly, metastasize widely, and afford limited opportunities for treatment with hope of cure. Over 50% of patients with these varieties of sarcoma die within 2 years, and less than 10% can be listed as 5-year survivals. The majority of survivors in this group have tumors which are polypoid and exophytic and invade the underlying myometrium superficially, if at all.

Metastases in cases of carcinosarcoma were usually of the carcinomatous component. In one patient the metastasis contained admixed carcinomatous and sarcomatous components. In another patient there was dissociation of the cellular components in the metastases, the ovary containing metastatic adenocarcinoma and a vaginal nodule containing pure metastatic sarcoma. In 10 of 25 cases a prominent clinical feature was a large polypoid mass protruding through a dilated cervical os in a postmenopausal woman whose presenting symptom was uterine bleeding. To some extent, length of survival was correlated with duration of symptoms prior to treatment. Excluding the pure homologous sarcomas, in 14 patients who are dead, the average duration of symptoms was 9.6 months, and the average survival time was 8.2 months; in 7 patients alive at the time of reporting, the average duration of symptoms was 2.3 months, and the average survival time was 39.6 months.

Treatment of patients with carcinosarcoma or mixed mesenchymal sarcoma must depend upon the extent of the disease at the time of diagnosis. If the tumor is polypoid and confined to the endometrium or has only superficially invaded the myometrium, total abdominal hysterectomy with bilateral salpingo-oophorectomy is sufficient. With extension beyond these limits, the prognosis is generally poor, and a course of supervoltage irradiation to the pelvis for palliative purposes is indicated. No results are reported with patients treated by radical hysterectomy, exenterative surgery, or chemotherapeutic compounds. The prognosis appears to be hopeless in the presence of extrapelvic disease.

The Histogenesis of Carcinosarcoma (Mixed Mesodermal Turmor) of the Uterus as Revealed by Tissue Culture Studies. A. Rubin. Am. J. Obst. & Gynec. 77:269-274 (Feb.) 1959 [St. Louis].

The histogenesis of carcinosarcoma of the uterus is obscure. Hence, because of divergent points of view, the study of carcinosarcoma grown in tissue cultures, where elements of exudation, inflammation, compression of cells, vascularity, tumor bed, and host response are absent, seemed to be a logical technique for attempting to learn more about such tumors. The author presents the history of a 57-year-old woman from whom a carcinosarcoma (mixed mesodermal tumor) of the uterus was removed. Two and one-half months after the operation the patient complained of vomiting and weight loss. Large abdominal masses were palpable. In the midvagina there were several friable, polypoid lesions. A similar mass protruded from the urethral meatus. Biopsy specimens of the vaginal and urethral tumors were used to prepare tissue cultures and microscopic sections. The microscopic picture was identical with that of the original uterine lesion. The patient was readmitted and given a course of nitrogen mustard intravenously. The abdominal mass appeared to grow smaller. No effect upon the urethral or vaginal lesions was noted. The patient died 4 months after hysterectomy.

In the tissue cultures prepared from biopsy specimens, 2 distinct cell types were distinguished. One cell type had the characteristics of carcinoma, the other of sarcoma. No intermediate cell types of evidence of transition from one form to the other were seen. These observations lend support to the thesis that carcinosarcoma is a distinct pathological entity in which carcinomatous and sarcomatous elements coexist, rather than merely an atypical or pleomorphic carcinoma. This is the first description of a human carcinosarcoma grown in tissue culture.

Syphilitic Foetus After Prenatal Penicillin Therapy. J. A. Burgess. Brit. J. Ven. Dis. 34:240 (Dec.) 1958 [London].

The prevention of congenital syphilis by the treatment of syphilitic pregnant women has been so successful that clinical manifestations of the disease in infants, after adequate prenatal penicillin therapy, are now seldom seen. In a 32-year-old woman, who attended an antenatal clinic, serological tests for syphilis were positive, the first positive report being obtained during the 16th week of pregnancy. Fetal movements ceased during the 21st week. Crystalline sodium penicillin in a daily dose of 1 million units was given for 15 days, beginning with the 22nd week of pregnancy. In the 27th week miscarriage of a macerated fetus occurred. A postmortem examination of the fetal liver, stained by Levaditi's method, showed the presence of numerous spirochetes which had the morphology of Treponema pallidum. Examination of the husband showed that he had late latent syphilis. It is suggested that antisyphilitic treatment should be given immediately to expectant mothers in whom the initial serologic tests for syphilis are unequivocally positive.

Vaginitis and Pathological States of Newborn Infants: Etiology of Infection with Staphylococci in Newborn Infants. J. Bret and C. Coupe. Presse méd. 67:216-217 (Jan. 31) 1959 (In French) [Paris].

Cultures were obtained from the vaginal canal of 300 parturients and from the nasal cavaties, mouths, and urine of their newborn infants so as to investigate possible transmission of pathogenic micro-organisms at delivery. Cultures were recovered from 200 women at delivery and from their newborn infants at birth and 6 hours, 24 hours, and 4 days after birth. Cultures were recovered from the remaining 100 women at admission and at delivery and from their newborn infants 24 hours, 4 days, 10 days, and 26 days after birth. Staphylococcus pyogenes var. aureus was recovered in the cultures of 46 women (15%) at delivery. Thirty-seven newborn infants (12%) were found to carry staphylococcus organisms at birth and 10 days afterwards. These organisms were present alone in 10 instances and were associated with either gram-negative bacteria or Candida albicans in 17 instances. Consequently, 37 of 46 mothers (or 82%) who carried pathogenic organisms at delivery transmitted them to their newborn infants. In 9 instances, in which labor was of short duration or in which a cesarean section was performed, the newborn infants were free of pathogenic organisms, although the organisms were present in the mothers. The presence of staphylococci was not observed in those infants whose mothers' vaginas were free of these organisms. Of 100 infants who were inspected on discharge, pathogenic micro-organisms were present in 27; 12 of them were infected at birth, and 15 after birth. This means that 47% of the infections took place at delivery.

Spontaneous disappearance of Staph. pyogenes var. aureus was observed in 4 infants (27%), and of C. albicans in 10 (60%). Of 14 infants who still carried pathogenic organisms 4 days after birth, 7 were affected with the following pathological states: purulent conjunctivitis (2), subcutaneous abscess (1), purulent rhinitis (1), parotitis attributed to staphylococci (1), and suppurative omphalitis (2). The micro-organisms observed in the foci of infection of these infants were of the same type as those identified in their respective mothers at delivery. To prevent transmission of pathogenic micro-organisms from parturients to newborn infants, prophylaxis and treatment for vaginitis of pregnant women, coupled with rigid control of nursery sterility, are recommended.

Sarcoma of the Uterus: A Report of 34 Cases. E. J. Crawford, Jr. and R. Tucker. Am. J. Obst. & Gynec. 77:286-291 (Feb.) 1959 [St. Louis].

This study was undertaken to correlate the clinical findings, diagnosis, management, and ultimate outcome in 34 patients with uterine sarcoma, who were seen during the 9-year period from 1948 to 1956 at 2 hospitals in Shreveport, La. One of the hospitals is a charity institution and a referral center; the other is a private hospital. Sarcomas constituted 2.6% of all uterine malignancies. Twenty-six of the patients had leiomyosarcoma; in 6 the leiomyosarcoma was primary (arising in the myometrium), and in 20 it was secondary (arising in a myoma). Of the other 8 patients, 3 had endometrial stromal-cell sarcoma, and 5 had mixed mesodermal tumors. The average age of the patients with leiomyosarcoma was less than 50 years; for those with the other 2 forms of sarcoma it was over 67 years. The majority of the patients had the triad of irregular bleeding, abdominal mass, and lower abdominal pain. These symptoms are not characteristic and are similar to those of other benign and malignant diseases of the uterus. The only preoperative diagnoses were made from curettement or biopsy. Two patients had tumors of the cervix, and diagnosis was made from biopsy. Two other patients had necrotic tissue in the vaginal vault, from which diagnosis was established. A diagnostic curettage was done 8 times in the patients with leiomyosarcoma; 3 cases were reported positive. In the endometrial stromal type the curettement yielded a positive diagnosis in all cases. In the mixed mesodermal tumors a curettement was done in 2 cases, and both were positive. The diagnosis of leiomyosarcoma was usually made on histological examination of the surgical specimen.

Three of the 26 patients with leiomyosarcoma were found to have inoperable disease. Sixteen of the remaining 23 patients were treated by total abdominal hysterectomy; 7 of them died, and 9 are living from 2 to 8 years after the hysterectomy. Of the 6 patients who underwent subtotal hysterectomy, 4 are dead, and 2 are alive more than 5 years after the operation. One patient who was treated by vaginal hysterectomy is still alive (3 years later). Operation was the treatment of choice. The operative mortality was 3.8%. Irradiation was of doubtful benefit. The extent of the tumor was the most important factor in prognosis. All the patients in whom the sarcoma extended outside the uterus are dead. Earlier diagnosis may possibly increase the survival rate. The 5-year survival rate in this series was 26.5%. There were no 5-year survivors in the endometrial stromal-cell and mixed mesodermal groups. The leiomyosarcoma arising in a fibromyoma seems to be the most favorable type of sarcoma.

PEDIATRICS

The Relationship Between Bronchiolitis and Childhood Asthma: A Follow-up Study of 100 Cases of Bronchiolitis. H. J. Wittig and J. Glaser. J. Allergy 30:19-23 (Jan.-Feb.) 1959 [St. Louis].

The high incidence of respiratory allergies in children with a history of bronchiolitis could be of significance for an etiological relationship between bronchiolitis and asthma. This prompted the authors to study 100 children with acute bronchiolitis admitted to the pediatric services of 3 major hospitals in Rochester, N. Y., between 1950 and 1957. The patients' ages ranged from 4 weeks to 4 years. Seventy-six patients were under the age of one year. The purpose of this study was to ascertain in how many of these 100 children bronchial asthma or other respiratory allergies developed subsequently and how many had a positive family history for allergy. Studies of hospital records and communication with the patients' families and their private physicians indicated that in 32 children bronchial asthma and in 17 upper respiratory disorders, perennial allergic rhinitis, or pollinosis developed subsequently. The diagnosis of asthma in the 32 children was made between 1½ and 2½ years after their original admission to the hospital with acute bronchiolitis. A reliable family history was available for only 83 of the 100 patients; 37 of these showed incidence of either asthma, pollinosis, or eczema. It seems fair to assume that acute bronchiolitis in infancy should be looked upon as a condition which is often followed by the development of respiratory allergic disease, particularly asthma, and appropriate prophylactic measures should be instituted.

Disturbances of Acid-base Equilibrium in Salicylate Intoxication. R. W. Winters, J. S. White, M. C. Hughes and N. K. Ordway. Pediatrics 23: 260-285 (Feb.) 1959 [Springfield, Ill.].

The 33 patients with salicylate intoxication reported ranged in age from 2 months to 19 years, but most of them were 3 years of age or less. Salicylate had been taken in the form of aspirin by 31 of the patients and in the form of methyl salicylate or phenyl salicylate by 1 patient each. In 16 instances the salicylate was accidently ingested; a 19-year-old girl had ingested aspirin in a suicidal attempt; in the remaining 16 persons poisoning resulted from therapeutic overdosage in the treatment of febrile respiratory infection, acute rheumatic fever, or rheumatoid arthritis. The total carbon dioxide content of the blood and the carbon dioxide tension (pCO_2) of the plasma were significantly reduced in nearly all the patients. The pH of the blood did not vary consistently: some patients were alkalotic, others were acidotic, while still others had no significant deviation in pH of the blood. There was evidence that many patients had a mixed disturbance in acid-base equilibrium, with primary disturbances in the metabolic and the respiratory components.

The nature of the metabolic acidosis was analyzed by a detailed study of the anions in the serum of 5 patients with this disturbance. A variety of anions, such as chloride, salicylate, and an undetermined anion, were present in excess; in one patient the concentration of phosphate was likewise elevated. There are indications that ketone bodies account largely for the undetermined anion fraction. The return to normal acid-base equilibrium was studied in 6 patients who presented with an acid pH. This group showed a tendency to recover through a point at which the pH of the blood was normal or even alkaline although the carbon dioxide tension was still low.

In 2 patients who initially presented with an acid pH, acute respiratory depression supervened after acute pulmonary edema. The respiratory depression was accompanied by a marked elevation of the carbon dioxide tension and a marked fall in the pH. One of these patients died; in the other ventilation was achieved by artificial means, and recovery resulted. The authors review the basic effects of toxic doses of salicylate: respiratory stimulation, changes in the metabolic rate, and disturbances in the metabolism of carbohydrate, protein, and fat. The pathogenesis of the acid-base disturbances is formulated in terms of these actions of toxic amounts of salicylate. Several factors may be important conditioning influences in the particular type of disturbance which develops in an individual patient. These factors are the age of the patient, duration of intoxication, type of intoxication (i. e., whether accidental or the result of therapeutic overdosage), and, perhaps, the amount of salicylate ingested.

Evaluation of the Efficacy of Lavage and Induced Emesis in Treatment of Salicylate Poisoning. F. J. Arnold, J. B. Hodges and R. A. Barta. Pediatrics 23:286-301 (Feb.) 1959 [Springfield, Ill.].

Since the authors recovered only minimal amounts of salicylate by gastric lavage in children with aspirin (acetylsalicylic acid) poisoning, they made experiments in dogs to ascertain the therapeutic value of gastric lavage and to compare it with the effect of emesis. Fasting dogs, 6 to 10 kg. in weight, were given sodium salicylate in tablet form in doses of 0.5 Gm. per kilogram of body weight, and lavage was performed or emesis induced at varying time intervals after ingestion. The lavage and emesis fluids were examined for the amounts of salicylate they contained.

It was found that in the recovery of the ingested salicylate the initial aspiration of the stomach before the introduction of the lavage fluid is equally as important as the succeeding lavage. Lavage carried out within 15 minutes is no more effective than emesis induced within 30 minutes of ingestion. Lavage carried out one hour after ingestion is inefficient and far less effective than emesis produced within the same time interval. Spontaneous emesis is not as effective as induced emesis. Emesis induced immediately, or even when delayed as long as 1½ hours after ingestion, appeared to be the more effective, and thus the preferable, form of therapy. Neither lavage nor emesis under the most optimal conditions was consistent in effectiveness, so that all patients after either form of therapy should be watched carefully for signs of increasing drug intoxication and should be treated if a specific form of therapy is available.

Serial Study of Bone Marrow in Hemolytic Disease of the Newborn (Erythroblastosis Fetalis). H. C. Dillon and W. Krivit. Pediatrics 23:314-322 (Feb.) 1959 [Springfield, Ill.].

Fourteen infants with erythroblastosis fetalis were studied, with particular reference to bone marrow activity and its relation to their anemia. Serial studies of the marrow were done in 12 of the 14 infants, and single specimens were examined in 2 infants. The purpose of this study was to determine the relationship between the degree of anemia and the normoblastic activity of bone marrow, as ascertained by morphologic techniques. On the basis of literature reports and the observations in this series of infants, true "aregenerative anemia" appears to be a rare occurrence. To suggest that the anemia of erythroblastosis is commonly due to a cessation of erythropoiesis seems totally unjustified, because these infants show hyperplasia of the marrow which is analogous to that seen in other compensated hemolytic anemias.

Hyman and Sturgeon had stated, and the authors agree, that a relative hypoplasia may occur as cell destruction exceeds cell production. This does not necessarily imply marrow failure or an "aregenerative state," but it may indicate that the balance can be in favor of blood destruction, and an anemia of some degree is the result. In a previous report, infants after exchange transfusion did show excessive destruction of donor erythrocytes. The rate of destruction of Rh-negative cells in erythroblastosis fetalis was twice that of normal. Some of the cases reported in the literature as "aregenerative anemia" lack adequate marrow studies and cannot be accepted as proved. It should be emphasized that it may be unwise to conjecture about the activity of the bone marrow from reticulocyte studies of the peripheral blood alone. In this series, the percentage of normoblasts in the bone marrow was increased in proportion to the degree of anemia.

The Problem of Early Diagnosis of Purulent Meningitis in the Nursling. G. Rottini. Minerva pediat. 10:1388-1398 (Nov. 24) 1958 (In Italian) [Turin, Italy].

The time of onset of various symptoms of purulent meningitis was studied in 51 nursing infants, 3 days to 12 months old, who were observed during a 5-year period. The significant symptoms of the disease had developed by the 4th or 5th day of illness. A temperature of 39 C (102.2 F) or over appeared on the first day in 23 children; in 10 children the temperature was 38 to 39 C (100.4 to 102.2 F), and in 10 others it was 37 to 38 C (98.6 to 100.4 F). Fever was most frequent in those close to one year of age. Early symptoms of intracranial hypertension appeared in a pattern inversely proportional to the ages of the children; on the first day these symptoms were most frequent and marked in infants, 9 to 12 months old; by the 4th or 5th day they had developed in most of the children. Early symptoms of meningeal irritation were most frequent in infants, 9 to 12 months old; second in frequency were the meningeal symptoms of infants ranging in age from birth to 3 months, followed by those in the age groups of 3 to 6 months and 6 to 9 months. Symptoms of brain involvement were most frequent in the youngest children, being present in 60 to 75% of the children within the first 48 hours of illness. The frequency of early symptoms of neurovegetative involvement increased in a pattern directly proportional to the ages of the children; 10 of the youngest children refused food on the first day of illness, and by the second day one-third of the children refused to eat. The author observed an almost constant association of symptoms of cerebral involvement and of purulent meningitis in these infants.

Still's Disease and Its Nosologic Limits. G. Verdura, N. Svilokos and L. Serafini. Minerva pediat. 10:1251-1267 (Nov. 10) 1958 (In Italian) [Turin, Italy].

The authors report on a boy, 4 years of age, with Still's disease. The first episode of the disease, consisting of high intermittent fever and rash, appeared at the age of 11 months. These symptoms recurred intermittently for a few days once a week. Early signs of fixation in flexion of the hands and legs were interpreted as manifestations of spasmophilia and, then, of arthritis. Administration of preparations of calcium, antibiotics, and antipyretics brought no benefit to the child. The subsequent signs and symptoms were progressive pallor, stationary body weight, and failure to develop walking capacity. A pleurisy with effusion was roentgenologically identified and cured in a few weeks. After 2 months of apparent improvement, when the child was 19 months of age, an episode of high fever, enlargement of the vertebrae in the lower section of the spinal column, pain on passive flexion, a marked degree of anemia, and deterioration of the general condition developed. The child was then referred to the clinic, with which the authors are associated, with the diagnosis of spondylitis. On admission the child appeared dystrophic, with very pale, inelastic skin, enlarged joints, muscular atrophy, fixation in flexion of the legs, enlarged and painless spleen, enlarged penis and scrotum but with testes normal in size. During hospitalization the child received successive therapies with antibiotics as well as Butazolidin, prednisone, and corticotropin (ACTH). Each therapy brought about slight improvement of the symptoms but failed to arrest recurrences. The therapy with isonicotinic acid, administered in daily doses of 20 mg. per kilogram of body weight for 10 months, arrested the recurrence of the disease and produced remission of all symptoms with the exception of a slight rigidity of head movement.

UROLOGY

Wilms's Tumor: A Report of 71 Cases. J. K. Lattimer, M. M. Melicow and A. C. Uson. J. Urol. 80:401-416 (Dec.) 1958 [Baltimore].

Wilms's tumor (nephroblastoma), one of the commonest neoplasms in childhood, apparently needs no longer be regarded as a hopeless disease. This is suggested by the findings in this review of 71 cases (67 proved), from the files of the pediatric urologic service of the Squier Clinic and the Babies Hospital in New York, from 1895 through 1956. "Abdominal mass" was the presenting symptom in 60% of the patients. Vomiting, abdominal pain, fever, or hematuria occurred in some of the children. Hypertension was found in 60% of those patients in whom the blood pressure was recorded. The erythrocyte sedimentation rate was determined in 20 patients, and of 11, in whom the range was high (35 to 90 mm. during the first hour), none survived. The urographic study was the most important single procedure in confirming the clinical impression of nephroblastoma.

Of the 25 patients treated before 1934, only 2 survived, whereas of the 42 treated between 1934 and 1956, 16 have survived 2 years or more. Preoperative irradiation proved unsatisfactory in the 4 patients in whom the full course was given. Better results were obtained with prompt nephrectomy and postoperative irradiation. Thirty-six of the last 42 patients were treated by nephrectomy, and of these 16 survived, 5 surviving so far from 2 to 5 years, 5 from 5 to 10 years, and the remaining 6 from 10 to 23 years. Patients who survived beyond 2 years usually continued to do well. Eighty-five per cent of the children who died after nephrectomy for nephroblastoma succumbed within 2 years.

The age of the patient at the time of surgery was an important factor in prognosis. Of those operated on during the first 2 years of life, 73.3% are alive, whereas only 18.5% of those operated on between the ages of 3 and 9 years are alive. Other factors important for a favorable prognosis were location of the tumor at the lower pole of the kidney, removal of the tumor with the capsule intact, and the absence of invasion or metastases. The prognosis was unfavorable when the child was older, when the tumor was on the upper pole, when the capsule was torn or had been penetrated by the tumor, when invasion or metastases were present, and when the erythrocyte sedimentation rate was above 35mm. during the first hour.

Aneurysm of Renal Artery: Report of Five Cases. B. R. Harrow and J. A. Sloane. J. Urol. 81:35-41 (Jan.) 1959 [Baltimore].

Since previous presentations, including comprehensive surveys, have discussed the etiology, symptomatology, and pathogenesis of aneurysm of the renal artery, the authors in this report add 5 new cases of saccular aneurysms, consider the indications for aortography, and discuss the treatment. Calcific shadows typical of renal artery aneurysms were observed in all 5 patients. In 1 of the 5 patients the aneurysm developed in a solitary kidney, the third instance of this sort reported in the literature. In another patient in whom an excretory urogram revealed 2 small calcific rings, 0.5 and 1.1 cm. in diameter, in the upper pole of the right kidney, suggestive of 2 renal artery aneurysms, a translumbar aortogram confirmed the diagnosis.

Noncalcified aneurysms of the renal artery have a high incidence of rupture, as proved by a survey of the literature. The noncalcific lesion is diagnosed only by aortography, operation, or autopsy. It has been discovered preoperatively with the use of translumbar aortography for hypertension, poorly or nonfunctioning kidneys, or unexplained extra renal or intrarenal noncalcified, space-occupying lesions. Operative intervention to prevent rupture and other complications is necessary in patients with nonopaque saccular aneurysms. Contrary to many previous reports, the authors believe that operation may be unnecessary with large and small calcified aneurysms in asymptomatic, normotensive, elderly individuals. Surgery is indicated if pain, hematuria, hypertension, or renal impairment occurs, and in youthful or pregnant patients.

With regard to aortography in the diagnosis of calcific rings, the authors say that the typical cracked-eggshell appearance of the usual ring shadow, located in the renal hilus on anteroposterior and oblique views, is so characteristic that usually aortography is unnecessary for diagnosis. With an atypical calcification, translumbar aortography is necessary to distinguish among aneurysms, calcified lymph nodes, cysts, neoplasms, old traumatic hematomas, and tuberculomas. The serious complications that have been known to occur in translumbar aortography can be avoided if the proper technique is employed. The authors demonstrate also that the intelligent use of adequate, closely supervised application of pressure to the abdominal wall during intravenous urography often eliminates the necessity of retrograde pyelography.

INDUSTRIAL MEDICINE

Long-Term Experience with Beryllium Disease: A Report of Twenty Patients. E. M. Kline and T. W. Moir. A. M. A. Arch. Indust. Health 19:104-109 (Feb.) 1959 [Chicago].

A report is presented on 20 patients with chronic beryllium disease who were followed up for 5 years. There were 7 men and 13 women, ranging in age from 25 to 44 years. Five persons were employed in the mixing and firing of zinc beryllium silicate lamp phosphor, and were exposed not only to zinc beryllium silicate but also to the dusts of beryllium oxide. Fifteen persons were employed in lamp factories where the fluorescent tubes were coated, lehred, based, inspected, and packaged for distribution to the consumer; the exposure of these persons was minimal. The data collected indicate that there was not only a quantitative but also a qualitative difference in exposure between the 2 groups. In the first group the average duration of exposure was only 12 months, as compared with the second group whose average exposure in the lamp factories was nearly twice that time (23 months). The average latent period of 2.9 years for the group exposed in the chemical plants was approximately half as great as that for the group exposed during the lamp manufacturing process. The differences in the attack rate, in the duration of exposure, and in the period of delay between the 2 groups are not readily explained by a sensitivity reaction, as suggested by other authors, but are rather indicative of differences in quantity and form of the disease-producing substance of beryllium.

Five patients of the first group received no specific treatment; 2 died, and the other 3 are in a bad condition. The 15 patients of the second group were treated with corticotropin, corticosteroids, or a combination of these agents in an average daily dose of 75 mg. (ranging from 25 to 150 mg.) for an average period of 4.5 years (ranging from 0.8 to 7.5 years). Striking but only transitory improvement has been obtained with corticotropin (or with corticosteroids) in some patients. The favorable response was particularly impressive in patients with rapid weight loss, anorexia, dyspnea, and pulmonary infection. The subsequent course of the disease, however, was unpredictable from the initial favorable response to the treatment, and the duration of remissions was not always a result of treatment. In 4 of the 7 patients who showed improvement after treatment, the remission was maintained without therapy for a period of from 1½ to 3 years. No patient was cured either spontaneously or as a result of treatment. Five patients died; the death of 4 was attributed to berylliosis, and that of 1 to an unrelated disease. Four patients are sufficiently well to perform light housekeeping chores; 6 are partially disabled; in the remaining 4 the disease has been gradually progressive despite steroid therapy, adequate rest, limitation of physical activity, and other supportive measures.

Complications, such as hemoptysis, pneumothorax, and renal stones, were frequent in the series presented, but the development of cor pulmonale was the most serious threat and is now regarded as a poor prognostic sign. The chest roentgenograms showed characteristic changes in the early stage of the disease which are indicative of berylliosis. As the disease progresses, the findings become less specific, and the roentgenograms may lose all similarity to the original appearance.

The Pathologic Changes of Chronic Beryllium Disease. H. R. Dudley. A. M. A. Arch. Indust. Health 19:184-187 (Feb.) 1959 [Chicago].

The observations reported were derived from a review of 58 patients with chronic beryllium disease in the Beryllium Registry. The chronic reaction to beryllium compounds is similar in each organ involved. Whether directly introduced or vessel-borne, beryllium compounds precipitate a lymphocytic, plasma-cell, and granulomatous reaction in the skin, liver, kidney, lymph nodes, and skeletal muscle. The myocardium, the spleen, and the pleura may be involved. The most important route of entry to beryllium into the body is by inhalation, and, since the beryllium compounds industrially used are poorly soluble, the lungs are the most frequently and seriously affected. The chronic active disease may yield to a chronic more indolent state; the transition is often marked by the development of fibrosis and of vesicular emphysema with persistence of lymphocytes. Pulmonary emboli are frequent, in addition to the occasional endarteritic changes seen in the involved lungs. Approximately 25% of the patients reviewed from the Beryllium Registry had small emboli in the peripheral vessels. Pulmonary emboli constitute a hazard for any debilitated patient, and they can be expected to increase in frequency if polycythemia, caused by chronic anoxia, is added to the disease pattern. Showers of small emboli from the veins of the extremities may produce exacerbation episodes in the respiratory difficulties of these patients.

Medical Aspects of Civil Jet Air Transport Operations. K. G. Bergin. J. Aviation Med. 30:22-28 (Jan.) 1959 [St. Paul].

This report covers the civil operation of Comet jet aircraft over a period of 8 years. With the exception of the intermission in flying after the misfortunes of some years ago, the experience covers a wide range of operations over land and sea in tropical and temperate climates. A previously held conception that pilots for jet aircraft should be of the fighter pilot mentality has been proved to be misguided, and, by the same token, any arbitrary age limit of those competent to fly is not supported by experience. While reaction time may be slower in an older person, in the final analysis of reaction to conditions due weight must be given to the value of experience in any set of circumstances—the older and more experienced pilot carrying out his task with an economy of thought and action which is not available to his less experienced colleague. The pilot must be adaptable and prepared to adopt new techniques; he must be mentally alert; he must be more than usually ready to think and plan ahead; and, most important, he must be prepared to be a fully working crew member. Integrated teamwork on the flight deck is the key to successful jet operations. A pilot's reaction times must be swift, because he is working to a much shorter time scale, and his instrument flying must be exceptionally good, as instrumental approaches call for precision and accuracy. Careful preflight training and flight simulator work are important.

Jet aircraft and their flying technique do not require exceptional standards of physical or mental fitness. If anything, the danger is that their good flying characteristics could lead to a mistaken impression by nonflying executives that they are easier aircraft to fly than current piston-engine types. This view must not be allowed to gain credence. The operation of flight-time limitations, stacking at airports, fuel reserves, and the tiring effects of manual flying of such a sensitive aircraft, should the automatic pilot fail, must be given due consideration. The ideal pilot for operation of jet aircraft is one who is methodical and clear thinking, who has a mobile mind, and who fits in readily with a team. Good flight planning is required, and a high standard of training and indoctrination is most desirable.

THERAPEUTICS

Clinical Experiences with the Vitamin B_{12} Factors III and III_m in the Treatment of Pernicious Anemia.

G. Böwing and F. Thedering Jr. Blut 4:349-366 (Dec.) 1958 (In German) [Munich, Germany].

Numerous substances have been identified, which are chemically and biologically related to cyanocobalamin and which belong to the vitamin B_{12} group of substances. To classify the known vitamins of the B_{12} group, the authors survey the structure of the entire complex. A central cobalt atom is surrounded by 4 pyrrole rings, so that a porphyrin-like macro-ring system results. This system of rings contains 6 conjugated double-bonds. In the side-chains the basic ring is substituted with methyl groups, acetamide groups, and propionamide groups, and short and long side-chains are arranged in the same manner as in uroporphyrin III. One of the propionic acid chains, by way of an amide-bond, is connected with aminopropanol, the hydroxy group of which is esterified with the phosphoric acid rest of the nucleotide. In the chemistry of vitamin B_{12} a nucleotide is that portion of the vitamin B_{12} molecule that consists of an amidozole base, D-ribose, and phosphoric acid. A nitrogen atom of the base is connected with the cobalt atom like a secondary valence. This is important for the biological action. Depending on the groups coordinated with the cobalt atom, there are cyanocobalamin, hydroxycobalamin, nitrito-cobalamin, cyanato-cobalamin, thiocyanato-cobalamin, and others. A list of the complete nucleotide-containing "cobalamins" shows that factor III of vitamin B_{12} is hydroxybenzimidazole-cobalamin, and factor III_m is 5-methoxybenzimidazole-cobalamin.

The authors discuss what parts of the B_{12} molecule determine its biological action, showing the relation between chemical constitution and biological effects. Of 14 patients with decompensated pernicious anemia, they treated 4 with factor III and 10 with factor III_m of vitamin B_{12}. All achieved full clinical and hematological remissions. The effect on the blood picture, on the general condition, and on the spinal degeneration was the same as that of pure vitamin B_{12}, vitamin B_{12} plus folic acid, or liver extract. Primary treatment with the oral administration of factor III or factor III_m plus intrinsic factor is possible, but treatment by injection is more reliable. Maintenance treatment by means of factors III and III_m of 49 patients with compensated pernicious anemia achieved complete clinical and hematological control so far over an average period of 20 months. The patients reacted in the same way as they did earlier to treatment with liver extract, with vitamin B_{12}, or with vitamin B_{12} plus folic acid.

The oral administration of factors III and III_m requires more careful supervision of the patient because of the danger of recurrence in this as in other oral forms of therapy. The dosage of factor III or factor III_m is of about the same magnitude as that of vitamin B_{12}. Tolerance for factors III and III_m was favorable; no undesirable side-effects were observed. The authors conclude that factors III and III_m can be recommended for the treatment of patients with pernicious anemia.

Triamcinolone in the Treatment of Allergic Conditions.

L. H. Criep. J. Allergy 30:50-60 (Jan.-Feb.) 1959 [St. Louis].

The author reports the results of treatment with triamcinolone (Aristocort) in 250 actively allergic patients (119 men and 131 women) of all ages. Many patients presented more than one type of allergy, the duration of which varied from 1 to 10 years. The initial dose of triamcinolone was as follows: 206 patients received 16 mg. daily, 9 patients received 20 mg. daily, and 35 patients received 24 mg. daily. The dose of triamcinolone was reduced by 2 to 4 mg. a day every 1 or 2 days. The maintenance dose was 2 mg. daily in 155 patients. The drug was withdrawn gradually. No sodium-restricted diet or potassium was prescribed. The duration of treatment with triamcinolone ranged from 2 to 18 weeks. Usually other antiallergic treatment was continued during and after steroid medication, thus making it possible to employ smaller doses of triamcinolone.

Laboratory studies revealed no marked changes as a result of triamcinolone therapy in maintenance doses of 2 to 4 mg. daily. The hemoglobin level, hematocrit reading, and red blood cell count were unaffected. Eosinopenia occurred in 95 of 203 patients in whom the blood cell count was done. The chest roentgenogram was unaffected. In 4 patients glycosuria developed, and 5 patients showed a suggestive diabetic sugar-tolerance curve. No change in nonprotein nitrogen level was seen. There was no evidence of hypercalciuria or hypokalemia and no significant changes in total protein or gamma globulin values. Analysis of a metabolic study in 6 patients with bronchial asthma of long standing, who were given 18 to 24 mg. of triamcinolone, revealed only slight changes in urine sodium and calcium findings.

Triamcinolone is about 1½ times as potent as prednisone as an antiallergic agent and gives marked clinical relief. The frequency and severity of side-reactions are about the same as those observed with other synthetic steroids, except perhaps for fewer instances of hypertension and gastrointestinal manifestations. Most of the more serious side-effects occurred when the dose of the drug exceeded 10 mg. a day. Weakness, sweats, and muscle cramps were common side-effects found in this series. Sodium retention, potassium depletion, and edema were not observed after administration of triamcinolone in the dosages used. Triamcinolone commonly causes diuresis. A note of caution is included with reference to the use of triamcinolone and other steroids in the long-term treatment of allergy. Patients have to be examined regularly while taking the drug. Only the smallest dosage needed to keep a patient comfortable should be employed. Patients should be urged to be conservative in the use of the drug, and the possible dangers of long-term use should be explained to them. Most allergic patients do well with usual antiallergic therapy and do not need steroids.

Triamcinolone, as well as other corticosteroids, is indicated in the treatment of allergy only when it is used under the following conditions: (1) purely as a temporary measure in acute transient disorders, such as dermatitis due to poison ivy; (2) when it is impossible to control disabling manifestations, such as intractable bronchial asthma, in spite of complete medical and allergic treatment; (3) as a crutch during the period in which medical and allergic studies are being conducted if other forms of symptomatic therapy are inadequate; (4) in the absence of any of the well-known contraindications to steroids; and (5) as a lifesaving procedure in status asthmaticus. This therapy should be undertaken on a long-term basis only after a careful appraisal of potential dangers as well as benefits. It is not to be used as a substitute for careful medical and allergic treatment. Particular caution is to be exercised in the long-term treatment of allergic children.

Fluoxymesterone ("Halotestin") in Advanced Breast Carcinoma. B. A. Stoll. M. J. Australia 1:70-74 (Jan. 17) 1959 [Sydney].

The effects of fluoxymesterone (Halotestin) in a series of 50 patients with advanced cancer of the breast were studied at the Peter MacCollum Clinic, Melbourne. Fluoxymesterone was administered by the oral route in daily doses of from 15 to 20 mg. to less than one-half of the patients, and was given in daily doses of from 25 to 45 mg. to the remaining patients. Definite improvement was noted in patients with soft-tissue metastases to whom daily doses larger than 20 mg. were given. The response to the treatment was analyzed in 22 patients with cancer of the breast with metastases to the bone. Relief of pain was obtained in 18 patients (82%), and recalcification of metastases, without simultaneous roentgenotherapy, in 3; in 1 of the latter the recalcification of metastases was obtained after 6 weeks of treatment, and in the other 2 within 8 to 10 weeks of treatment. The duration of remissions effected in the majority of patients with metastatic breast cancer was 3 to 6 months only, but the favorable response was maintained for 9 months or longer in 3 patients. The results obtained with fluoxymesterone were similar to those observed from testosterone propionate.

Twenty-nine patients presented soft-tissue growth involving breast, lymph nodes, or cutaneous nodules; a favorable objective improvement was noted in 8 (27%), which was better than that observed from testosterone propionate. The best response was obtained in patients with primary growth, also in one patient with a recurrent tumor. The improvement has been maintained now for 6 months or longer in 3 patients, and they are still in remission although fluoxymesterone treatment has been discontinued. The 5 patients with pulmonary metastases showed no regression of lung opacities, and there was no reduction of the pleural effusion.

The urinary calcium levels were not in correlation with the clinical remissions: a fall in the urinary calcium excretion may occur (which is probably due to the calcium-retaining properties of fluoxymesterone), with no concomitant clinical improvement. On the other hand, 2 patients with persisting high urinary calcium levels showed marked remission of symptoms. Side-effects were, in general, few. It is emphasized that the greatest advantage observed in fluoxymesterone therapy was that even the administration of clinically effective doses caused little or no masculinization.

Clinical Evaluation of a New Sulfonamide with Prolonged Action. G. Fontana. Minerva med. 49:4726-4730 (Dec. 15) 1958 (In Italian) [Turin, Italy].

Forty-one patients, male and female, 16 to 71 years of age, with various inflammatory diseases of the respiratory tract were treated with Orisul [3-(*p*-amino-benzolsulfonamido)-2-phenyl-pyrazol], a new sulfonamide preparation with prolonged action. Each patient received 2 Gm. of the drug the first day, and 1 Gm. per day from the second day on. The 2-Gm. daily dose was continued for a few days in patients with the severe form of the disease. Good results were obtained in 27 patients; the fever dropped within 24 to 48 hours and the values of erythrocyte sedimentation, leukocytes, and $alpha_2$ globulins became normal. Fair results were obtained in 9 patients; improvement followed from 5 to 7 days after the beginning of treatment. No results were obtained in 5 patients, who had to be treated later with antibiotics. Twelve of 15 patients with acute bronchitis improved rapidly; the symptoms regressed in the same manner as if antibiotics had been used. The drug had a less beneficial effect in 5 patients with subacute bronchitis or chronic bronchitis which had become acute. Fair results, though, were obtained in 3 of these patients and good results in 2; discharge of mucus and elevation of temperature improved after a few days of treatment. The substitution of Orisul in patients who had received penicillin caused no change in the course of their improvement. The drug had an effect similar to that of antibiotics in 15 patients whose bronchopulmonary diseases were not too severe, but substitution or integration therapy with antibiotics had to be used in other patients with the severe form of these diseases. The drug was well tolerated by all the patients.

Gastroduodenal Perforations and Prolonged Steroid Therapy in Lipid Nephrosis. J. Cathala, C. Polonovski and M. de Boissière. Presse méd. 67:41-43 (Jan. 10) 1959 (In French) [Paris].

The authors describe 2 cases of lipid nephrosis, one in a 14½-year-old boy and the other in a 2½-year-old boy, which ended fatally after the patients were treated with long courses of prednisone (delta cortisone). Autopsy showed that the cause of death was unquestionably related to the occurrence of duodenal and gastric perforation. The authors state that the usual treatment of lipid nephrosis includes a daily dose of prednisone until edema and albuminuria have disappeared and plasma disequilibrium is corrected. Then there is a maintenance period in which prednisone is taken 3 or 4 days of the week for several months. The posology of the drug is uncertain, and many believe that it is necessary to reach a certain dosage level of effectiveness. This leads to increasing doses in difficult cases up to amounts which far exceed what would ordinarily be used, considering the weight and age of the patient.

The 14½-year-old boy had a recurrent attack of nephrosis and was in danger of cerebral accidents and anasarca. Abdominal symptoms appeared to be in direct correlation with the bout of nephrosis. A decision to use prednisone was not without realization of the patient's intolerance to the drug and of the fact that his father had an ulcer. It was decided that steroid therapy was necessary, and corticotropin (ACTH) was substituted for prednisone. The patient died during the night after the new treatment was begun. Anatomic examination revealed punctiform purpuric spots in the gastroduodenal mucosa and a perforation of the duodenum. Histological examination revealed ulcerations of the duodenum and stomach, which were characteristic of ulcerations of prednisone origin.

In the second patient an attack of severe abdominal pain was treated as a nephrotic attack. Altogether this boy had received 920 mg. of prednisone over a period of 51 days, being given up to 50 mg. per day although he weighed only 12 or 13 kg. (between 27 and 29 lb.). After an apparent cure, he was hospitalized again and given potassium chloride, penicillin, and a French steroid preparation (Cortancyl) for grippe. Three days later he died, after an abdominal attack, of what seemed to be nephrosis and hematemesis, and in shock. Anatomic examination showed isolated perforation of the posterior wall of the stomach. In both this and the first patient the painful abdominal syndrome did not appear to be of a nature other than that of previous abdominal episodes. Circumstances were not favorable for a precise diagnosis or surgical intervention in either patient.

The cause of the nephrotic abdominal syndrome is infection in most cases, but other mechanisms may be at fault. Anatomic or functional disturbances in the adenomesenteric system or vena cava and changes in the protein-lipid equilibrium of the plasma can play a role. The difficulty lies in deciding whether an abdominal attack is the result of an infection in a patient with lipid nephrosis or whether it is a mechanical accident which may be the consequence of treatment. Steroid therapy risks causing lesions of the digestive mucous membrane, ranging from erosions and ulcerations to hemorrhagic necrosis and acute perforation of an organ. The question of treatment is very difficult, since steroid therapy is at present well accepted and it brings much success. The authors think that this therapy should be limited to less prolonged periods. The original basic and maintenance treatments, which could last for 6 to 8 months, might be more suitably limited to 3 or 4 months. Perhaps some abandoned methods which had some success (for example, thyroid opotherapy) could be used with a rigorous and prolonged antibiotherapy. This might improve the prognosis of nephrosis and avoid the definite risk of perforation from steroid therapy. The distressing problem of treatment for lipid nephrosis remains to be solved. This practical difficulty is the consequence of lack of knowledge of the nature and etiology of the disease.

Disseminated Lupus Erythematosus: Analysis of Cases of 100 Patients Treated with Corticosteroids: Comparison with 25 Untreated Patients. J. Jalil M., R. Armas Cruz, J. Harnecker J. and others. Rev. méd. Chile 86:717-732 (Dec.) 1958 (In Spanish) [Santiago].

One hundred twenty-five patients with disseminated lupus erythematosus were observed for at least 8 years in the hospital of the University of Chile in Santiago. Most of the patients were women. One hundred patients were treated with corticosteroids; 25 "controls," who were observed before the advent of corticosteroids, were treated with vitamins, analgesics, and colloidal gold sulfide. The incidence of clinical signs and symptoms, the laboratory findings, and the distribution of predominant lesions were approximately equal in both groups before treatment. Among the controls, 4 patients had 1 or 2 recurrences which lasted between 1 and 3 years. Four of the controls disappeared from observation; in the remaining 21 the disease followed a typical progressive, fulminant course. All these patients died within 2 months to 4 years from appearance of the symptoms (death rate of 100%). The main cause of death was lupus itself.

In the patients treated with corticosteroids, the time between appearance of symptoms and hospitalization varied between a few weeks in the acute cases and a few months in the chronic cases. *Cortisone was given in an initial dosage of from* 200 to 500 mg., followed by maintenance doses of between 6.25 and 12.5 mg. The maintenance therapy was sustained for a period of 1 to 8 years. Prolonged treatment resulted in improvement of the general symptoms, the joint pains, and the cutaneous lesions in 67, 81, and 72% of the cases respectively. All other symptoms of lupus either did not change or became worse. Thirty-three patients discontinued the treatment during an apparent cure or remission of the disease; 9 did not report for observation; 19 had recurrences between 1 month and 6½ years after discontinuation of the treatment; and 5 were still under observation, in an excellent condition, between 5 and 7 years after they had discontinued the treatment. By the end of 8 years, in the whole group of treated patients, 8 had discontinued the treatment, 50 with severe and moderately severe forms of the disease had died, and 42 are living and continuing the treatment. Of the 50 patients who died, survival between initial treatment and death varied between 2 months and 3 years in 22 patients with severe and moderately severe forms of the disease who had early, sufficient, and maintained treatment; it varied between 1 month and 4 years in 28 patients who had either late or insufficient treatment. The cause of death in these treated patients was lupus itself in 36% of the cases and intercurrent diseases in 64%. Forty of the 42 patients who have survived for more than 8 years are ambulant under minimal dosage of corticosteroids and carry on almost normal activity. Only 2 patients are invalids because of lupus. The authors conclude that corticosteroid treatment lowers the death rate from 100% in those not so treated to 54% in those treated. The earlier the start of the treatment, the better the results in prolonging survival with attenuated symptoms.

ANESTHESIA

Fluothane: A New Nonexplosive Volatile Anesthetic Agent: Preliminary Report on 2,000 Administrations. H. M. Ausherman and A. Adan. South. M. J. 52:46-52 (Jan.) 1959 [Birmingham, Ala.].

Fluothane (2-bromo-2-chloro-1, 1, 1-trifluoroethane), a clear volatile liquid which mixes well with oxygen and is not explosive or flammable, was given a trial as the principal anesthetic agent in 2,000 patients, between the ages of 5 weeks and 82 years, who were subjected to almost every type of surgical procedure. There were few poor-risk patients in this group. The length of operation in 66% of the patients was less than 2 hours. The semiclosed technique of administration utilizing the Copper Kettle, one of the most accurate vaporizers, was employed in 1,386 patients. Due to the *ease with which one can administer a lethal con*centration of this agent, the authors believe that a machine with such an accurately calibrated vaporizer is essential to the safe and proper use of this potent agent. The results obtained with this drug suggest that this halogenated ethane is of *more than passing interest in filling the need for a* controlled volatile nonexplosive anesthetic agent. The authors were impressed with the rapid smooth induction, the ease of maintenance with present equipment for anesthetization, the reduction of salivation, the reversibility of the agent's action by controlling the vapor concentration, the adequate muscular relaxation for most surgical procedures, the rapid recovery time without excitement, the reduction in postoperative nausea and vomiting, and the minimal complications.

The commonest complication in administering Fluothane was too deep an anesthesia, especially with the use of the open-drop technique in children. Bradycardia occasionally occurred but usually was relieved by intravenous administration of atropine and by reducing the vapor concentration. Like cyclopropane, Fluothane increases cardiac irritability, and therefore drugs, such as epinephrine, should not be used with this agent. With Fluothane, vagal action on the heart predominates, perhaps explaining the slowing of the pulse, the lowering of the systolic blood pressure more than the diastolic resulting in reduced pulse pressure. The fall in blood pressure appears to be in direct proportion to the concentration of the vapor and especially to the rate at which the concentration is increased. Inhalation of Fluothane produces some degree of respiratory depression, but one of its desirable properties is the ease with which respiration can be controlled and spontaneous respiration be resumed when desired. In using the agent by the open-drop technique or by any method, the anesthetist must be alert and should be experienced. Properly used, it is one of the most useful anesthetic agents to date and deserves further study.

Fluothane: A Modern Substitute for Chloroform. H. R. Griffith, J. G. Robson, W. G. Cullen and D. M. M. Gillies. Anesth. & Analg. 37:316-321 (Nov.-Dec.) 1958 [Cleveland].

The authors' observations in the operating room and in the laboratory and a review of the literature convinced them that halothane (Fluothane) is a potent and versatile drug which may be used by preference in situations which demand a noncombustible controllable anesthetic agent. Halothane is not the harmless, foolproof drug that some of the anethesiologists have dreamed about as an agent to replace all explosive substances. However, it is somewhat less toxic than chloroform. Halothane is no drug for the amateur anesthesiologist. It should be administered in low concentration, with adequate oxygen and preferably some nitrous oxide as a vehicle, and adjustment of the concentration according to the patient's condition must be possible. Proper equipment is necessary for its relatively safe use, together with the most meticulous watchfulness, intelligence, and good judgment on the part of experienced anesthesiologists. Where these prerequisites prevail, halothane may acquire a most useful place in future anesthesiology.

Comparison of Meprobamate, Pentobarbital and Placebo as Preanesthetic Medication for Regional Procedures. E. I. Eger and H. H. Keasling. Anesthesiology 20:1-9 (Jan.-Feb.) 1959 [Philadelphia].

The authors carried out a double-blind comparative study of meprobamate, pentobarbital, and a placebo of lactose in 668 patients, between the ages of 16 and 96 years, who were to undergo surgical treatment in the University Hospitals or the Veterans Administration Hospital in Iowa City, for which a regional anesthetic was to be administered. Of the 668 patients, 199 were aged less than 60 years (young patients), 265 were over 60 years of age (older patients), and 204 were patients having some mild to severe mental impairment due to diseases of advancing age (senile patients). An attempt was made to determine the effect of each of the 3 preparations on the patient's apprehension, cooperation, drowsiness, reaction to painful stimuli, talkativeness, nausea, and emesis. The anesthetist's evaluation of the adequacy of each premedicant was also determined.

Either meprobamate or pentobarbital was more effective than placebo as premedicant in young patients, but this difference tended to become less in the older age group and to disappear in the senile group. In general, meprobamate or pentobarbital prevented an increase in apprehension, as viewed by either patient or anesthetist, this effect being most marked in the young patients, and absent or undiscernible in the senile group, while the older group may represent an intermediate between the other two. Cooperation was affected by meprobamate and pentobarbital in a significant manner only in the young patients in whom a decrease in cooperation was prevented. Sleep was significantly and favorably affected by the preceding administration of either meprobamate or pentobarbital as compared with placebo. Both meprobamate and pentobarbital caused an increase in drowsiness, the latter drug also causing a significantly greater degree than the former. No difference in the reaction to painful stimuli could be detected among the patients receiving either one of the two drugs. Talkativeness, emesis, and nausea were apparently unaffected by the drugs, although, in the case of nausea, increase in dosage was followed by decreased incidence; the effect of increasing the dose of placebo, however, was indistinguishable from the effect achieved by the increased dosage of the other drugs. Over all, the effect of meprobamate and pentobarbital is considered to be a favorable one and is most apparent in the group of young patients. No distinct advantage is seen in the use of one of the drugs as opposed to the other.

BOOK REVIEWS

Drinking and Intoxication: Selected Readings in Social Attitudes and Controls. Edited by Raymond G. McCarthy, Associate Professor, Health Education, Yale University, New Haven, Conn. Cloth. $7.50. Pp. 455, with illustrations. Publications Division: Yale Center of Alcohol Studies, New Haven, Conn.; Free Press, Glencoe, Ill., 1959.

Although this book is a symposium by 59 authors, expressing many viewpoints, the editor has successfully managed to present the problems of drinking, its complications, and possible remedies. After excellent chapters on the physiological and psychological effect of alcohol comes a most interesting discussion of the drinking habits of numerous cultures, from biblical times to the present. The illustrations are particularly well chosen and represent ancient statuary, bas-reliefs, and story-telling tapestries. Other chapters deal with the drinking habits of various ethnic groups, high school students, and college students, and contributory cultural, religious, and ethical factors. The account of the controversy between "wets" and "drys" is informative, and the motivation of the two groups is discussed in a logical manner. The reader will be particularly impressed, favorably or otherwise depending on his psychological background, with the chapter by Myerson, Alcoholism: The Role of Social Ambivalence. Hedonism, the worship and seeking of pleasure, is contrasted with asceticism, which runs counter to desire and satisfaction and when carried to its logical extreme is against reproduction: "Man is born into sin. He becomes a third excretion born between urine and feces." Man's ambivalence concerning sexual matters also applies to the use of alcohol. The author advises a middle course: "Against unwise hedonism, against extravagant asceticism, we need to build a code of temperate hedonism and successful self-control." The book should appeal particularly to the student of history, the sociologist, and the scientist. The worshipper of Bacchus may be persuaded to mend his ways, while the ascetic "dry" may feel that his convictions are not represented with sufficient vigor. Finally, this excellent symposium has succeeded in its purpose of furnishing knowledge, which will probably do more to control the improper use of alcohol than legislation alone.

Tumors of the Lungs and Mediastinum. By B. M. Fried, M.D., F.C.C.P., Associate Attending Physician, Montefiore Hospital, New York. Cloth. $13.50. Pp. 467, with 235 illustrations. Lea & Febiger, Washington Sq., Philadelphia 6, 1958.

This book, although not all-inclusive, presents most of the important data pertaining to tumors of the lungs and mediastinum. Much of this material is controversial, and the author has attempted to present the various theories clearly in an unbiased manner. Most of this study deals with bronchogenic cancer. An attempt was made to study, whenever possible, the incipient stages of this disease. This was done by obtaining records of previous hospital admissions and of private physicians who had treated the patients at an earlier period. This is no mean task. The second section is devoted to a study of tumors and cysts of the mediastinum. The frequency of these conditions is stressed as is the differential diagnosis between primary and metastatic lesions. Chapter 17, which discusses tumors of the thymus gland and thymic cysts, is especially good. The book is well illustrated with roentgenograms, photographs, line drawings, and photomicrographs. Bibliographic references are given at the end of each chapter. This book can be highly recommended.

Chemical Concepts of Psychosis: Proceedings of the Symposium on Chemical Concepts of Psychosis held at the Second International Congress of Psychiatry in Zurich, Switzerland, September 1 to 7, 1957. Edited by Max Rinkel, with Herman C. B. Denber. Cloth. $7.50. Pp. 485, with illustrations. McDowell, Obolensky, Inc., 219 E. 61st St., New York 21; George J. McLeod, Ltd., 73 Bathurst St., Toronto 2B, Canada, 1958.

This book is divided into (1) historical survey; (2) reports of chemical, clinical, and physiological studies on lysergic acid diethylamide (LSD-25), mescaline, epinephrine metabolites, chelation, serotonin, indole, and central and peripheral fluids; (3) neuroleptic patients; (4) genetic, biological, and philosophical considerations of schizophrenia; (5) surveys of theoretical and methodological aspects of the problem; and (6) a general appraisal by Gilbert Cant, the medicine editor of *Time*. It is pointed out that "Any illness, including mental illness, can be discussed in a variety of ways: chemical, biological, pharmacological, sociological, through to psychology, philosophy and religion, not to mention medicine and psychiatry"; that biological and chemical theories concern the present symposium; that current chemical theories chiefly envision endogenous toxic factors resulting either from imbalances of chemical substances normally occurring in the body or from the development of new substances; and that the new chemical approach arose from the observation of the psychotomimetic effects of a variety of drugs, particularly mescaline and LSD-25. An effort has been made to imitate mental disorders by the use of such drugs, to discover variable factors and controls, and so to unmask possible chemical bases for psychotic states. Most of the symposium is

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

devoted to a description of the behavioral effects of the chemical substances mentioned above in experiments on animals, as well as their subjective effects on normal and psychotic human subjects and to the theoretical interpretation of the results.

It is difficult to restrain one's enthusiasm for the chemical attack on the psychoses, as so vividly documented and brought up to date in this book. Weary with age-long discouragements in the therapy of the psychoses the physician eagerly embraces the possibility of a new understanding and a new and hopeful approach. Without question, the chemical concept of psychosis offers the most optimistic prospect in psychiatry today. One's enthusiasm is, however, like that experienced at the birth of a baby—directed to the promise of the future; for the accomplishments so far, while exciting, are only the first steps toward a distant goal. In the present volume much is said about chemical formulas and pharmacological theory, but there are, inevitably, uncertainties and often contradictions in detail, which eventually will be resolved. The fact that schizophrenic states are not convincingly imitated by any drugs used is recognized in this book, but there is scant appreciation that whatever schizophrenia is, it is not a single disease but a congeries of more or less related states. The promising chemical concepts of psychosis here outlined must be adapted to a more precise subdivision of symptomatology before precise formulations of chemical factors in mental illness can be made. Precision is even more necessary in attempts to modify, intensify, or diminish psychotic symptoms by chemical means in experimental work with human patients. Chemists working in this fertile field must be guided and informed by the best clinical skill in this delimitation of psychiatric categories. The medical reader will need to keep clearly in mind that while the so-called psychoses—chiefly schizophrenia and the affective psychoses—appear likely to be metabolic disorders, and so basically chemical, the neuroses are rather acquired ways of life, learned distortions of character, and unlikely to be vulnerable to chemical analysis. This book is highly recommended to every physician as presenting in easily intelligible terms the latest work in a promising field with tremendous implications for the future.

The Middle Ear. By Heinrich G. Kobrak. Contributors: J. E. Fournier and others. Foreword by John R. Lindsay. Cloth. $15. Pp. 254, with illustrations. University of Chicago Press, 5750 Ellis Ave., Chicago 37; Cambridge University Press, Bentley House, 200 Euston Rd., London, N. W. 1, England; University of Toronto Press, Toronto 5, Canada, 1959.

This book is timely, because the middle ear has assumed increasing importance in recent years as new operations have been devised to deal with the problem of hearing loss in both suppurative and nonsuppurative states. Untimely, however, was the sudden death of the author, in 1957, before the completion of this work. He had pioneered in demonstrating the acoustic vibrations of the eardrum and ossicular chain by means of stroboscopic cinematography. His "staging" of these highly successful films revealed him to be a master showman as well as an outstanding educator. Such observations and his knowledge of the subject in general form the basis of his contributions, mainly to the first part, discussing the middle ear in health and disease. Alvar Wilka and J. E. Fournier also contributed to this part. The second part deals with treatment. Dr. John R. Lindsay, who also wrote the foreword, discusses otosclerosis and fenestration; Dr. Samuel Rosen, the mobilization and fenestration of the stapes; Dr. Kobrak, the treatment of middle ear deafness by prosthesis; Dr. Horst Wullstein, tympanoplasty; and Dr. Fritz Zoellner, the plastic surgery of the sound conduction system of the middle ear.

To the extent that modern otology is dedicated to the elimination of conductive deafness this book provides a summary of the past and present knowledge of the subject; but the problems and failures in otosurgery are not sufficiently evaluated for the novice in this field of endeavor. The chapter on stimulus and function is excellent. As is so frequently the case in a work which represents a number of contributors an integrated assessment of each is lacking, but each person's current thought, which in this type of surgery is undergoing such rapid modification that tomorrow it may be outmoded, is coherently presented. The classification of the types of functional repair of middle ear lesions offered by Wullstein is valuable in understanding the problems involved. Zoellner's enthusiasm for the acoustic probe is not shared by all, but his warnings regarding the problems of achieving ideal results in closing the air-bone gap are much appreciated. Not enough emphasis is given to the adequate treatment of lesions before functional considerations. There is an excellent reference list for each chapter. Some of the black and white photographs and color plates leave much to be desired.

Physical Examination of the Surgical Patient. By J. Englebert Dunphy, M.D., F.A.C.S., Professor of Surgery, Harvard Medical School, Boston, and Thomas W. Botsford, M.D., F.A.C.S., Clinical Associate in Surgery, Harvard Medical School. Second edition. Cloth. $8. Pp. 375, with 203 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1958.

This new edition of a comprehensive volume on the examination of the surgical patient emphasizes what the surgeon may learn by special attention to history-taking and a careful and knowledgeable elicitation of physical signs. The tools employed are the eyes, ears, fingers, and nose. Clear-cut illustrations portray the various conditions discussed in the text, and enough clinical information is given to enable the reader to understand what a physical finding signifies. Every area of the body is covered except the eye, ear, nose, heart, and lungs, the authors believing that these areas are well presented in standard textbooks on physical diagnosis. That the surgeon is not relieved of careful examination in these fields is emphasized, since reliance on medical or other colleagues prevents personally knowing and evaluating all the data.

A perusal of all the information offered reveals a tremendous amount of material available to the reader, whether he be a student or practitioner; and even the teacher would do well to review this book. Several special chapters are particularly informative; these deal with examination of the head and neck, the abdomen of infants and children, the infected hand, the peripheral blood vessels, ulcer and gangrene of the extremities, examination for the detection of cancer, and the general principles and specific examinations of the traumatically injured patient. Such patients are encountered more and more in industry and transportation and are rightfully receiving greater attention.

It is true that laboratory tests and x-ray studies are providing much information about diseases and injuries, but fundamentally the beginning is the physician-patient relationship initiated by listening to what the patient has to say, asking searching questions, and making a careful and thorough examination. This book should be of immeasurable aid in maintaining a high standard of acumen in the time-honored skill of examining the patient.

Rapports présentés au III^{ème} Congrès international d'allergologie, Paris, 1958. (Proceedings presented at the IIIrd International Congress of Allergology.) Edités par B. N. Halpern et A. Holtzer. [In French, English, German and Spanish.] Cloth. 6,000 francs. Pp. 940, with illustrations. Ernest Flammarion, 22 rue du Vaugirard, Paris 6e; Congrès international d'allergologie, 197 boulevard Saint-Germain, Paris, France, 1958.

In recent years the concept of allergy has begun to permeate many fields of medical research and clinical medicine, including infectious diseases, collagen disturbances, and autoimmune manifestations. These trends are reflected in this book. The symposiums presented deal with asthma, emphysema, the properties of allergic antibodies, recent advances in clinical allergology, the biochemical aspects of hypersensitivity (histamine, serotonin, acetylcholine, and slow-reacting substance), and autoimmune and isoimmune reactions (blood, encephalomyelitis, kidney, lupus and other collagen diseases, and homografts), atopic dermatitis, and allergic problems in different parts of the world. The contributors to this volume include Sir Henry Dale, Pasteur Vallery-Radot, Charles Eoeffler, Peter Forsham, Elvin Kabat, Merrill Chase, Pierre Grabar, C. Jimenez-Diaz, Harry Alexander, Murray Peshkin, H. O. Schild, Richard Schayer, Bernard Halpern, W. D. M. Paton, Robert Good, W. J. Harrington, Max Samter, J. Dausset, P. Miescher, Guy Voisin, Marion Sulzberger, W. Jadassohn, R. L. Mayer, Bram Rose, William Sherman, and many others. Each brings his particular subject up to the minute. The result is that the book is an exposition of the status of clinical and experimental allergology more up to date and more detailed than any textbook. More than half of the articles are in English, while those in French, German, or Spanish have complete summaries in English. This volume should be profitable not only to allergists, but also to immunologists, internists, dermatologists, pediatricians, and progressive physicians in general.

Heart Disease in Infancy and Childhood. By John D. Keith, M.D., Assistant Professor of Pediatrics, University of Toronto Faculty of Medicine, Toronto, Richard D. Rowe, M.B., F.R.C.P., Clinical Teacher, Department of Pediatrics, University of Toronto Faculty of Medicine, and Peter Vlad, M.D., Instructor in Pediatrics, Department of Pediatrics, University of Buffalo School of Medicine, Buffalo. Cloth. $22.50. Pp. 877, with illustrations. The Macmillan Company, 60 Fifth Ave., New York 11; Brett-Macmillan Ltd., 25 Hollinger Rd., Toronto 16, Canada, 1958.

Seldom has a more satisfactory book appeared on this subject. It covers its field thoroughly and scientifically. It is voluminous yet both readable and conveniently organized for reference purposes. Its chapters are well arranged. Its writing is not dogmatic, and its bibliography is complete. The diagrams and photographs are instructive and illuminating. It should be in the library of every pediatrician and cardiologist, and should prove a useful reference to the general practitioner. This review is short because there is nothing controversial in the book. No single chapter or subject is selected for criticism or praise because they are all of equally high quality.

Practical Dermatology. By George M. Lewis, M.D., F.A.C.P., Professor of Clinical Medicine (Dermatology), Cornell University Medical College, New York. Second edition. Cloth. $8. Pp. 363, with 121 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

In the preface to this new edition the author states, "As expressed in the preface to the first edition, this book, designed as a text for medical students, a practical guide for general practitioners, and an aid in orientation for other specialists, was written to meet the often expressed desire of my students to have a concise and well-illustrated text which would still serve their needs after they enter practice. It seeks to describe, as succinctly as possible, the clinical features and the methods of management of the more common skin disorders. Emphasis throughout the text is centered on (a) means to accurate diagnosis and (b) selection of appropriate treatment. To the student and practitioner recognition and identification of skin lesions pres[illegible] the outstanding dermatologic problems, but a chan[illegible] is often difficult and challenging." [illegible] at this tir

All of these objectives have been successfully attained. The author does not claim to have produced an all-inclusive reference work, but the descriptions of the dermatoses are brief and accurate. The limitations of space do not permit controversial discussions of cause and treatment, and some of the author's colleagues may take exception to some of his statements concerning both. The photographs are excellent and are arranged in unusual groupings of four and six to a page with the legends below. The legends were difficult to follow because of lack of differentiation in the typography. This volume is a worthy successor to the first edition and certainly meets the desires of students to have a "concise and well-illustrated text which would still serve their needs after they enter practice." The publishers are to be congratulated on the excellent compositing of this volume.

Growth and Development of Children. By Ernest H. Watson, M.D., Professor, and George H. Lowrey, M.D., Associate Professor, Department of Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor. Third edition. Cloth. $7.75. Pp. 334, with 75 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

This is the third edition of a text which was last edited in 1954 and reprinted in 1956. Since its original publication in 1952 it has become the "bible" for students and young pediatricians preparing for examinations by the American Board of Pediatrics. This edition retains much of the material of the previous ones, but changes and additions have been made in every chapter except the first. Many charts, tables, and graphs are included for summarizing purposes, but the authors are quick to point out that average figures thus arrived at may not apply to the individual. The entire chapter on the role of the endocrine glands has been rewritten, but unfortunately the publication date did not allow for the inclusion of recent interesting information about masculinization of the female fetus due to the administration of progesterones during gestation. The chapter on heredity and environmental factors is based on the assumption that there are 48 chromosomes in man. A footnote states that recent studies indicate that there are 23 pairs of chromosomes in man rather than 24 pairs as has been taught in the past, but the authors believe that in order to avoid confusion the old concept should be temporarily retained. Statistics in human heredity are still based on the old number of 48 and probably will continue to be for some time. The chapter entitled Behavioral Development has been changed to Behavior and Personality to emphasize the greater interest in the area of personality development. Over 100 new references have been added and it is apparent that a new edition of this excellent text is a worthwhile addition to recent literature on this subject.

Clinical Orthopaedics. Number Twelve: Fall, 1958. Anthony F. DePalma, editor-in-chief. With assistance of associate editors, Board of Advisory Editors, and Board of Corresponding Editors. Cloth. $7.50; $6 to sustaining members. Pp. 327, with illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada, 1958.

This volume is similar in format to the preceding ones in the series. The first article, historical in nature and dealing with the life of Dr. Buckminster Brown, is interesting, and the series dealing with the lives of early orthopedists is well done. Too many of the younger orthopedists do not realize the importance of the contributions of the pioneers in their field, and these articles are an excellent historical review. The first portion of the book deals primarily with problems of disability evaluations and various rehabilitation programs and in general the scope, techniques, and conclusions are well founded. The fact that rehabilitation is a team effort is emphasized. The second section of the book is devoted to general orthopedics and contains many interesting articles. One is on whiplash injuries of the cervical spine. It is felt the term "whiplash" should be deleted as a diagnostic term and "cervical strain or sprain" be substituted. The last portion of the volume has a very interesting article in which the author correlates the changes in the skeleton of the gorilla with those in that of man. The last article, on the appearance of a sarcoma after a surgically treated fracture of the tibia, is a brief but interesting case report. In this excellent volume the photographs and roentgenograms are of high quality.

Staphylococcal Infections. By Ian Maclean Smith, M.D., Ch.B., F.R.F.P.S.G., Assistant Professor and Chief, Infectious Disease Division, Department of Internal Medicine, State University of Iowa, Iowa City. Paper. $4.25. Pp. 180, with illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

This is a brief, practical, working manual dealing primarily with the clinical manifestations of staphylococcic infection. The manner of presentation is simple and categorical. This has obvious advantages to the practitioner and to the reader who wants a gallery of thumbnail sketches of the infections caused by staphylococci, but the critical reader may wonder if matters are really so cut and dried. A brief résumé of the biology of Staphylococcus is followed by chapters on diseases of the skin, respiratory infections, osteomyelitis, the gastrointestinal system and abdomen, septicemia and endocarditis, miscellaneous problems, diseases of animals, and the treatment of staphylococcic diseases. This is a useful volume but it is not to be compared with such a scholarly work, for instance, as "Staphylococcus pyogenes and Its Relation to Disease," by Prof. Stephen D. Elek of London, which has simultaneously become available through the Williams and Wilkins Company of Baltimore.

QUESTIONS AND ANSWERS

PUBLIC WATER SUPPLY

To the Editor:—*Please comment on a community water supply on which the following report was made: actual hardness, 2.4 grains per gallon; compensated hardness (computed from actual hardness, iron content, and sodium content), 6.0 grains per gallon; iron, 1.8 ppm; sodium salts, 1.1 ppm; alkalinity, 2.8 (expressed in grains per gallon of $CaCo_3$); and suspended solids or turbidity, none. The acidity in the sample was caused by the presence of free carbon dioxide. It was estimated that the water sample as received contained about 100 ppm of free carbon dioxide. For an accurate determination of the carbon dioxide content, it is necessary to follow a special sampling procedure and to analyze for the carbon dioxide at the job site.*

R. F. DeWitt, M.D., Plymouth, N. H.

Answer.—The analysis indicates that the water corresponds in general to that from wells in the New England area. In hardness it is high for a soft water, and this is the case also for sodium salts and for alkalinity. The high iron content is undoubtedly of more significance than the hardness from the standpoint of the household or industrial use of the water. If troubles from the presence of iron in public water supplies are to be avoided, it is generally recommended that the iron content be no higher than 0.3 ppm. The iron in ground waters is due to the presence of this element in the earth's crust. The iron dissolves in ground water particularly when there is an excess of carbon dioxide and an absence of oxygen in the underground source. When a well taps this strata, the water, when first drawn, may be clear and colorless. After being in contact with the air, however, it loses its excess of carbon dioxide and the iron then tends to precipitate and form a brownish turbidity. When this water is used, the iron will collect as rusty stains on plumbing fixtures, glassware, laundry, and other articles with which it comes in contact. For this same reason the water is unsuitable for a number of industrial uses, including paper making, laundering, and dyeing. From the standpoint of human health, the water is not likely to be dangerous. When treatment plants are available for public water supplies, any excess iron can be removed by aeration, the use of coagulants, and filtration. Removal of minerals from water by ion exchange resins is also possible.

POSSIBLE TUBERCULOSIS WITH LEUKEMIA

To the Editor:—*A 78-year-old man has had chronic lymphatic leukemia for years. His leukocyte count is now 30,000, with 60 to 70% lymphocytes. Two years ago nodules appeared in his neck and subsequently in his elbows and groin. The nodules were diagnosed by the pathologist as being malignant lymphosarcoma. These have responded well to x-ray therapy, the amount of irradiation required being small. Roentgenograms of the chest were consistently negative until in May, 1958, when a mass was noted in the right lung. A pathological fracture developed in the right clavicle. With the increasing spread of the lesion, a small dose of x-ray therapy was given to the right lung, producing a severe physical reaction. Sputum examined subsequently was said to contain tubercle bacilli on slide, culture, and animal inoculation. Bronchoscopy, four months later, gave the impression that the lesion was not tuberculous but neoplastic and not necessarily related to the leukemia. Sputum examinations, after the patient had been taking PAS and isoniazid, were reported by different laboratories as negative, as containing photochromogens, and as being positive for tubercle bacilli. Animal inoculation is now in progress. Should this patient be given a course of nitrogen mustard? There has been a weight gain of about a pound a week. Anemia (hemoglobin 8 Gm. per 100 ml.) has been corrected through cell mass transfusion. Physically, the patient appears well and is without fever or cough. Roentgenograms taken in August and December showed some extension of the mass. Should this patient be isolated, and what treatment is recommended?*

Virginia Downes, M.D., Milwaukee.

Answer.—It is not unusual for lymphocytic leukemia to pursue a benign course in persons beyond 65. The appearance of cervical, epitrochlear, and inguinal adenopathy is more probably related to the leukemia than to malignant lymphosarcoma, but it is difficult to differentiate histopathologically between these conditions. The good response to small doses of x-ray without subsequent reappearance of other nodes gives further support to this point. It was not stated whether there was a change in the hemoglobin or platelet level at this time.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

man has had long-standing vesical neck obstruction in which time his sphincters have become impaired. This often will cause a patient to dribble. This consultant, therefore, recommends increasing the daily fluid intake to 3,000 cc., exercising the sphincter at the time of voiding, the use of proper therapy depending on bacterial sensitivity, and patience.

AUGMENTATION MASTOPLASTY

To the Editor:—*What is the current status of the use of plastic inserts to supplement meager breasts? Please comment on safety; percentage of good immediate and long-term results; consequences of failure; and preferred type of procedure.* *C. O. Murray, M.D., Crockett, Texas.*

Answer.—Augmentation mastoplasty as currently performed has not been accepted as a good procedure by most plastic surgeons. Theoretically, small breasts need bulk to fill them out. To do this, one should use some type of autogenous graft. A free fat graft from the buttocks should be the material of choice, but unfortunately fat transplants do not survive well. Some surgeons have buried plastic sponges beneath small breasts. While this material is relatively inert, it is still a foreign body. It produces some inflammatory foreign body reaction which makes the breasts become stony hard. In others, the reaction is so great that the material has to be removed. The surgical treatment of this complication may be difficult because of the fibrous tissue reaction that has developed. While no cases in human beings have been reported, it is known that these plastic materials can produce carcinoma in experimental animals.

PAROSMIA

To the Editor:—*A 17-year-old woman has always had a keen sense of smell. In the last two to three years odors have bothered her. In the past year a cafeteria was installed in the high school she attends, and the smell of cooking foods has nauseated her. This has become so severe recently that the smell of some foods has caused headache and severe nausea. She had marked tenderness over the duodenum. She was placed on an ulcer diet and the abdominal soreness improved. The smells have continued to nauseate her. The only other pertinent factors include hay fever and moderate nervousness. Can you suggest any further treatment?*

R. S. Srigley, M.D., Altus, Okla.

Answer.—Parosmia, or perverted sense of smell, it is organic, is always cortical in origin. Thus, lesions of the uncinate gyrus or disease of the tip of the temporal lobe might produce a disagreeable olfactory sensation. These may be associated with seizures or constitute a seizure in the areas described previously. With this in mind, an electroencephalogram might be helpful in diagnosis. If the tracing demonstrates dysrhythmia in one or the other or both temporal lobes, investigation of the type of lesion would be important. If there is no tumor or other organic focal disorder, one would expect good results with anticonvulsant therapy. The physician should also be on the lookout for local nasal conditions such as empyema of the maxillary sinus and ozena from chronic atrophic rhinitis. These conditions should suggest consultation with a rhinologist. When the possibility of organic disease is ruled out, it is suggested that this patient might have hysterical parosmia. A careful psychiatric history should be of value. In hysteria, the whole function of the nose (as comprehended by the patient) is lost. If the situation is of psychic origin the answer is psychotherapy. It is difficult to see the connection between the duodenal tenderness and the parosmia.

PHOSPHATASE LEVELS

To the Editor:—*In a patient having 9.2 King-Armstrong units of acid phosphatase and 72 King-Armstrong units of alkaline phosphatase, is such an acid phosphatase level of any importance?*

Joseph Burns, M.D., Miami Beach, Fla.

Answer.—The exact interpretation of this rise in acid phosphatase level associated with a substantial elevation in alkaline phosphatase level is not possible without more clinical information, but the general principles underlying the interpretation of such results are outlined below. The determination of serum acid phosphatase level, that is, the phosphatase activity at pH 4.9, represents the activity of a distinct enzyme and not the residual activity at this pH of the alkaline phosphatase. In other words, it is possible to have alkaline phosphatase levels 40 to 50 times the normal value without having any increase in the acid phosphatase level.

The serum acid phosphatase determination performed with beta-glycerophosphate as the substrate rarely shows elevations in conditions other than carcinoma of the prostate. Such conditions as fecal impaction or prostatic massage may cause slight transitory elevations, but the King-Armstrong method in which phenylphosphate is used as substrate shows slight or moderate elevations in patients who do not have carcinoma of the prostate. Such elevations have been reported in patients with familial splenic anemia, metastatic carcinoma of the breast in women, Paget's disease, and various inflammatory diseases. In the patient mentioned, the elevated alkaline phosphatase level is undoubtedly due to an osteoblastic lesion or to an obstructive process in the liver. The moderate elevation in acid phosphatase level (performed by the King-Armstrong method) may be due to any of the conditions listed above.

IRRITABILITY OF MYONEURAL JUNCTION

To the Editor:—*Recently, several patients have shown evidence of either increased irritability of the myoneural junction or primary muscle fiber hypertonicity in conjunction with such chronic states as sprains, myositis, poliomyelitis, or virus encephalomyelitis (Guillain-Barré syndrome). These patients, after such exertion as playing in a gym class, walking a little more than average, or using the previously involved muscles in physical activity, have what may be termed a "charley horse." What causes this condition? Quinine has been given in doses of 0.3 Gm. and has been successful in some but not in others. What is the best treatment?*

Earl F. Hoerner, M.D., Orange, N. J.

Answer.—No evidence exists in favor of increased irritability of the myoneural junction or of the muscle fibers in any of the conditions named. While the possibility of facilitation of reflex spasm of muscles exists in poliomyelitis and in virus encephalomyelitis by reason of involvement of internuncial neurons, this neurological explanation not only is speculative and not applicable to the other conditions mentioned but also is not of interest to the questioner. No muscular lesion is common to the group of conditions listed, but where muscle weakness is evident sprains occur much more easily. Similarly, when repair processes are incomplete after sprains or myositis, overactivity or trauma may easily lead to additional soft tissue injury and inflammation because of the susceptibility of the delicate vessels and fibers of the repair tissue. If this explanation is correct, proper support and a graduated program of activity would be indicated, and, empirically, this is successful. It is doubtful whether any drug would have any appreciable influence on this process. The trial of medicaments used to treat diseases involving overactivity of the myoneural junction, myotoma congenita, dystrophic myotonia, and paramyotonia probably would not be indicated.

BANKED BLOOD

To the Editor:—*May jaundice be caused by banked blood that has been processed for over 14 days? What is the maximum time processed blood may be stored before use for transfusion?*

Joseph T. Phillips Jr., M.D., Norton, Va.

Answer.—Whole blood drawn under recommended conditions into acid-citrate-dextrose solution and properly stored is clinically useful for 21 days after venesection. Deterioration of stored blood does occur, however. Such deterioration is minimal for the first 10 days of storage and then increases steadily. Deterioration is judged by the survival of erythrocytes after infusion into the recipient. Blood stored for 21 days has a 70% survival rate, i. e., 70% of the infused erythrocytes exhibit normal persistence in the recipient, while 30% are removed from his vascular system within 24 hours after infusion. It is these nonviable erythrocytes that provide hemoglobin and eventually bilirubin and, in some cases, jaundice. Such jaundice appears and disappears within 24 hours of infusion. The 21-day limit for bank blood storage is based on clinical study and experience as being tolerable.

Release of 20 Gm. of hemoglobin via nonviable erythrocytes is associated with an increase of 1 mg. per 100 ml. in serum bilirubin levels. Mollison estimated that 75 Gm. of hemoglobin would have to be released in vivo within an hour or two to produce clinical jaundice. The quantity of blood being infused and the basic health of the recipient must also be considered. The use of almost outdated donor blood should be avoided if possible, particularly in large amounts, in transfusing patients with known liver deficiencies. Such situations seldom arise, because most blood banks try to balance supply with demand so that blood will be used long before the expiration date.

OBESITY IN YOUNG BOY

To the Editor:—*A 12-year-old boy has sex infantilism with obesity (adiposogenital dystrophy). He has been given weekly injections of chorionic gonadotropin and 30 mg. of thyroid extract daily. He has continued to gain weight despite a rather limited diet, and the genitalia are still immature and show no evidence of normal growth. He has recently been given 5 mg. of methyltestosterone twice daily. What further treatment is recommended?* *C. W. May, M.D., Tacoma, Wash.*

Answer.—With the patient only 12 years of age, one would be skeptical of the diagnosis of adiposogenital dystrophy in the absence of clinical and/or laboratory evidence of an intracranial tumor, cyst, or injury or previous encephalitis. His obesity may have no relationship to this syndrome but may be exogenous due to excessive eating; furthermore, the small genitalia may be relative, due to an abundance of fat in the pubic region. Small genitalia before puberty may be physiological. If treatment is indicated, chorionic gonadotropin may be given in doses of 1,000 I.U. three times weekly for six weeks, followed by 5 mg. of methyltestosterone twice daily for six weeks, with these drugs alternated for several months according to the clinical response. In addition, the calorie intake should be controlled by a diet with 1,000 to 1,250 calories daily. It may be necessary to evaluate emotional factors and correct these if possible. If weight cannot be reduced by diet alone, an appetite depressant may be needed, such as 10 to 15 mg. of prolonged-action dextro amphetamine sulfate given once daily after breakfast. Unless this boy has evidence of hypometabolism, there is no indication for the administration of dessicated thyroid. Failure of response to this regimen by the time puberty should appear (13 to 14 years of age) warrants a thorough endocrinological investigation.

RECURRENT CARBUNCLES

To the Editor:—*A 35-year-old woman has had six separate episodes of skin infection, usually large carbuncles, during a nine-month period. Each lesion was located in a different part of the body, usually above her eyes or on her arms. Culture on one occasion revealed Staphylococcus pyogenes var. aureus, which responded each time to erythromycin. All lesions required incision and drainage but cleared with the usual treatment and without complications. The patient's brother has diabetes but her own urine was negative for sugar on numerous tests. Use of hexachlorophene soap has been tried for short periods but not continuously. What would be the best prophylaxis against further skin infections?*

M.D., Utah.

Answer.—In such cases long continued prophylactic measures are required. This means a constant effort should be made to maintain a state approaching surgical cleanliness of the entire skin surface. There should be a brief bath every night with hexachlorophene soap. After this the skin should be dried, and then 70% ethyl or isopropyl alcohol should be applied to the entire body surface. For maximum protection, the alcohol may be applied night and morning. If this leaves the skin too dry, a bland oil may be applied afterward. The patient must be cautioned against fingering or picking at the skin, because infection is often conveyed in this manner. The towels, underwear, nightwear, and bed-linen should be boiled whenever they are laundered. An autogenous vaccine might be helpful, but one should not place too much reliance on this. In view of the family history, an occasional blood sugar estimation would seem advisable. For the treatment of active lesions, the erythromycin would appear to be satisfactory.

PAINFUL LAVAGE OF EXTERNAL AUDITORY CANAL

To the Editor:—*Why do some patients experience severe pain with lavage of the external auditory canal?*

Clinton F. Carrougher, M.D., Brooklyn, N. Y.

Answer.—It is assumed that the pain referred to was associated with attempts to remove impacted cerumen. This may occur because the skin of the external auditory canal is extremely sensitive to pain, and, in some instances, impacted cerumen is hard and almost calcareous in composition so that, when it begins to move out of the external auditory canal with lavage, it acts as an abrasive on this sensitive area. Again, if the wax is hard and lies beyond the isthmus of the external auditory canal, its passage through the isthmus may produce a great deal of pressure against the skin in the isthmus and cause pain.

PERSISTENT PYURIA

To the Editor:—*A patient with a chronic urinary infection has been unresponsive to treatment with sulfisoxazole, nitrofurantoin, and chloramphenicol on separate occasions. Culture of the urine showed a gram-negative rod, probably a Proteus, although the exact organism was not identified. Sensitivity studies revealed resistance to all antibiotics tested. The patient is asymptomatic, but the urine shows a marked pyuria. What treatment should be given?*

A. F. Stratton Jr., M.D., Cocoa, Fla.

Answer.—Since the organism in this infection has not been identified, it would be difficult to suggest what antibacterial agent might be most effective. If sensitivity studies did not include kanamycin, this drug should be considered and sensitivity tests made. It is effective against some types of Proteus, all other gram-negative bacilli except Pseudomonas, and all common coccic bacteria except enterococci. Kanamycin is administered, preferably, in a dosage of 0.5 Gm. intramuscularly every 12 hours for six days, although many infections will respond to 1 Gm. given intramuscularly every 24 hours for six days.

MEASUREMENT OF REACTION TIME

To the Editor:—*What are the most practical clinical methods and equipment for the measurement of reaction time, where job safety demands average or above average general alertness? Does the measurement of the reaction time of the ankle jerk have any special validity for this purpose?*

Philip A. Fuqua, M.D., Richland, Wash.

Answer.—The ankle jerk reflex time would have no value as a measure of a person's ability to respond in complex job situations. In the latter motivation, attention and accuracy of judgment are more important than simple measurements of the time required for nerve impulses to travel to and from the spinal cord. A simple visual motor reaction time measurement is described by Schwab (*Neurology* 8:719, 1958). More complex reaction time tests requiring discrimination between signals may be of more value. The advice of a psychologist trained in these methods may be of value in devising tests applicable to the job situation at hand.

HOUSE APPROVES RESEARCH MONEY BOOST

The House ignored administration economy warnings and voted a large increase in funds for medical research. Acting on an appropriations measure carrying money for the Labor Department and the Department of Health, Education, and Welfare, the lawmakers okayed a boost of more than 50 million dollars for research programs of the National Institutes of Health.

All told, NIH would receive $344,279,000 under the House bill, compared with the $292,700,000 requested. The extra 50 million dollars was distributed about equally among the institutes concerned with cancer, mental health, heart disease, dental health, arthritis and metabolic diseases, allergies, neurology and blindness, and general research.

The House Appropriations Committee, which handled the legislation, criticized the administration for not seeking more money for the programs. In a report, the majority of the committee said those who prepared the budget "obviously had been assigned the task of making it appear that the budget represented progress in the field of medical research when the true facts are that in a desperate attempt to present, on paper, a balanced budget, the Bureau of the Budget, or someone in authority, had even gone so far as to set back the medical research program."

Although the administration requested the same sum for NIH that Congress approved last year, the lawmakers contended that rising operating costs would mean a restricted program this year.

The committee said that there is so much hope for medical research progress that this is no time to curtail the programs. Any reduction at this time for the cancer program, it said, "would be a gross foolishness."

Other sections of the measure approved by the House and sent to the Senate would (1) provide $143,700,000 for hospital construction grants, a boost of $42,500,000; (2) appropriate 30 million dollars for construction grants for state and local health research facilities, 10 million dollars more than requested; and (3) earmark $45,500,000 for Indian health facilities, more than 2 million dollars above the budget figure.

Replying to the congressional criticism, Arthur S. Flemming, Secretary of Health, Education, and Welfare, declared that "every statement and figure presented to the committee was presented in good faith." The report, he said, "seeks to convey to the American public the impression that this administration is unwilling to request adequate support for the activities of the National Institutes of Health. . . . This impression is clearly misleading."

A. M. A. STATES POSITION ON HEALTH INSURANCE FOR FEDERAL WORKERS

The American Medical Association told Congress that any voluntary health and medical insurance program for federal workers should steer clear of establishing medical fees and should cover already-retired [illegible]

In a [illegible] Olin Johnston (D., S. C.) of the Senate Labor and Public Welfare Committee, Dr. F. J. L. Blasingame, A. M. A. Executive Vice-president, renewed the organization's support for the principle of an insurance program for civilian government workers similar to those now used by many private companies.

A Labor and Public Welfare subcommittee headed by Sen. Richard Neuberger (D., Ore.) has wound up hearings on the issue and is considering what kind of legislation to approve.

Some changes in the major measure before the subcommittee—a bill introduced by Sen. Johnston—were suggested by the A. M. A. official. "It is our belief that satisfactory amendments could be made rather easily within the framework of this legislation," he declared.

Five broad recommendations were made by the A. M. A. They were that the program should permit a realistic choice of plan by the individual employe; permit all qualified carriers to offer coverage; require financial participation by the employe in paying premiums; provide for a minimum of governmental regulatory authority over participating plans; and allow adequate prefunding for persons who retire after July 1, 1959, as well as a method by which those who retired before that date can participate on a contributory basis.

In addition, said Dr. Blasingame, "it is our definite recommendation that fee schedules not be established by the (Civil Service) Commission." He noted that it was not clear from the language of the measure whether this would be possible. Instead, he said, there should be authorization under the major medical program for payment of a stipulated percentage of the "usual and customary" charges, as most private policies specify.

"The most objectionable features of the bill," said Dr. Blasingame vest authority in the CSC to select "one or more insuring companies" to provide group major medical coverage, and the assumption by the government of the entire cost of this insurance. The A. M. A. official also said language should be changed to make it clear that Blue Cross and Blue Shield could underwrite major medical coverage.

COMMITTEE REVISES RADIATION DANGER LIMITS

A Committee of radiation experts downgraded the radioactive peril of strontium-90 but at the same time calculated that another radioactive byproduct of nuclear tests—cesium-137—is more dangerous than hitherto believed.

According to the National Committee on Radiation Protection and Measurements, civilians may consume through food and drink as much as 100 micromicrocuries of strontium-90 over a lifetime without exceeding maximum permissible concentrations. The previous level was 80 micromicrocuries.

However, the experts slashed by two-thirds the amount of cesium-137 that could accumulate safely in the bodies of workers at atomic installations.

Strontium-90 is the element that in large quantities can cause leukemia and bone cancer. Cesium-137 can cause genetic damage. The levels of both in the atmosphere and in food and drink have been subjects of controversy over whether nuclear tests are depositing too much radioactive matter.

The Committee on Radiation Protection is composed of government and private scientists. Its danger levels are used as guidelines by the government.

At present, the Public Health Service is conducting nationwide tests of milk to determine the amount of strontium-90 in the fluid. So far, the levels have remained well below maximum permissible concentrations. However, Dr. Francis J. Weber, Chief of the PHS Division of Radiological Health, told a House Appropriations Subcommittee recently that there is a rising trend in the radioactive content of milk. He said this will continue until 1970 or 1975 and that the level may reach the maximum permissible concentration. "When that might occur, we do not know," he said.

MEDICAL SCHOOL ENROLLMENT SEEN INCREASING

The long-term increase in medical students will be much greater than the increase in the population, the Executive Vice-president of the American Medical Association said in a letter placed in the Congressional Record.

The A. M. A. official, Dr. F. J. L. Blasingame, said, "The future, I believe, looks bright. Each year for the past 11 years, the number of students enrolled in approved medical schools has increased."

The statements were made in a letter to Rep. Clark W. Thompson (D., Tex.), who had asked for information on "the prospects for an adequate supply of physicians to meet the needs of our growing population."

Dr. Blasingame said that enrollments in medical schools are strictly determined by the individual school, not by the A. M. A. He also declared the medical profession "welcomes one-time federal grants for medical school construction and renovation as well as federal grants for basic research." But Dr. Blasingame said that "the profession has been opposed to continuing federal aid for operating expenses because of the potentialities therein for federal control."

FDA ACCUSES CALIFORNIA VITAMIN FIRM

The Food and Drug Administration has filed criminal charges against a California laboratory for making allegedly false claims about vitamin capsules and mineral tablets. The firm, Visan Nutritional Laboratories, Burbank, was accused of violating the Federal Food, Drug and Cosmetic Act in papers filed with the U. S. District Court in Los Angeles.

According to the FDA, the company falsely claimed that its product—Vi-San Food Supplement Therapeutic—was an effective treatment for a wide range of health problems and diseases, including lusterless eyes, cancer, deafness, blindness, emotional instability, and cerebral palsy.

Maximum penalty for each count of violating the act by a company is a $1,000 fine. Five charges were leveled against the company by FDA, but no individuals were named.

DANGEROUS CONTACT LENS CLEANER

The Food and Drug Administration has warned persons who wear contact eyeglasses to avoid using a product called Barnes-Hind Wetting Solution; the cleanser is distributed across the United States and is sold to practitioners who prescribe contact lenses.

FDA said the product is nonsterile and that a dangerous infection may occur in the eye if any injury or infection is present. A bacterium, Pseudomonas aeruginosa, that was isolated in one lot can cause blindness. The manufacturer, Barnes-Hind Ophthalmic Products, Inc., Sunnyvale, Calif., and the government are attempting to recall all outstanding stocks.

MISCELLANY

The Senate voted to extend the federal Air Pollution Control Program until 1964. The measure also would increase the authorization for the program from 5 million dollars to $7,500,000 a year. Under the program, the government provides grants for studies and research in the field of air pollution.

The Public Health Service awarded a $2,900,000 contract for construction of a 200-bed PHS hospital at Gallup, N. Mex. It will be the largest Indian hospital in the country.

The National Institutes of Health awarded 18 grants totaling $498,790 to support the training of research scientists in eight basic medical and health related sciences. The money will go to 18 institutions and universities in 10 states to provide support for training in the following fields: biochemistry, research anesthesiology, research dermatology, genetics, pharmacology, experimental pathology, physiology, and anatomy.

The Veterans Administration reported that an oral dental examination in the physical check given patients entering hospitals has proved valuable in diagnosing cancer. Since oral examination was adopted generally by the VA two and a half years ago, some 700 cases of malignancy of the mouth, tongue, and throat have been found that might otherwise have been unidentified until too late for successful treatment.

Pro-Banthīne® with Dartal®

Pro-Banthīne—
unexcelled for relief of cholinergic spasm—
has been combined with
Dartal—
new, well-tolerated agent for stabilizing emotions—
to provide you with
Pro-Banthīne with Dartal—
for more specific control of functional gastrointestinal disorders, especially those aggravated by emotional tension.

Specific Clinical Applications: Functional gastrointestinal disturbances, pylorospasm, peptic ulcer, gastritis, spastic colon (irritable bowel), biliary dyskinesia.

Dosage: One tablet three times a day.

Availability: Aqua-colored tablets containing 15 mg. of Pro-Banthīne (brand of propantheline bromide) and 5 mg. of Dartal (brand of thiopropazate dihydrochloride). G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

CARCINOMA OF COLON AND RECTUM

SURVEY OF SURGICAL MANAGEMENT IN CENTRAL NEW YORK STATE

Robert O. Gregg, M.D., Bruce E. Chamberlain, M.D.
and
Arthur A. Vercillo, M.D., Syracuse, N. Y.

Acute obstruction appears to be the complication of cancer most likely to end fatally. This survey of surgical practices in central New York state communities of varying size revealed a 22% operative mortality among patients admitted with this complication, contrasted with a 3.7% mortality among all other patients who underwent planned operation. In well over 60% of the former, clear-cut symptoms of obstruction had been present for more than three months. Anemia occurred less commonly in the entire series of 623 patients than is usually reported. This and the presence of an abdominal mass do not unfavorably affect prognosis except in lesions of the transverse colon, sigmoid flexure, or rectum. Anterior resection should be the operation of choice for most lesions in the upper part of the rectum or lower part of the sigmoid flexure.

WE, as a committee to survey the work of 32 fellow members of the Central New York Surgical Society, are presenting a review of the results of treatment of patients suffering from cancer of the colon and rectum, during the period 1947 through 1951. We believe that this survey represents a true picture of the behavior of and the management of cancer of the colon in upstate New York. The patients were all managed within a few miles of their homes by members of this society. It would appear that there was very little selection of cases in this series. The survey was conducted primarily to see how well our management measured up to that recorded by the major clinics and to find out in what respect we might improve our therapy.

In the course of analysis of these cases we made several observations which we believe are particularly worthy of general publication. 1. There was a lower incidence of anemia in this series than usually reported—in particular among patients who harbored carcinoma of the ascending colon. 2. Carcinoma arising below the pelvic peritoneal reflection represented a remarkably low percentage of all the cancers in this group. 3. In this group of cases anterior resection appeared to be the procedure of choice for lesions arising from 10 to 15 cm. from the anal verge. 4. We were able to arrive at some conclusion concerning the relative merits of the various types of intestinal preparation. 5. The lethal effects of acute intestinal obstruction were again emphasized, in terms of immediate surgical risk as well as in ultimate survival. 6. The prognostic significance of anemia and palpable mass was determined. 7. The age of the patient was found to be a most important factor in five-year survival.

Method of Survey

A résumé of each individual patient's record was submitted by the surgeon who had cared for the patient. All the case records were reviewed by this committee. The data submitted were therefore those of the 32 surgeons submitting case records on the colon. The conclusions from the analysis of the material are our responsibility.

Location of Lesions.—The intestine was divided into the usual segments for the analysis, except that we omitted the term rectosigmoid and considered all lesions found in this general area to be in either the sigmoid flexure or the rectum. Any growth whose lower border was at or below 14 cm. from the dentate line was arbitrarily considered to be in the rectum. Any lesion arising above this level was considered to be in the sigmoid flexure. Similarly, any lesion found at operation 3 in. or more above the peritoneal reflection was arbitrarily grouped in the sigmoid flexure, and any growth situated below this level was grouped in the rectum. The rectal lesions were divided into four groups: those rising above the peritoneal reflection, those involving the peritoneal reflection, those rising below the reflection from 5 to 9 cm. above the dentate line, and those arising from 4 cm. and below.

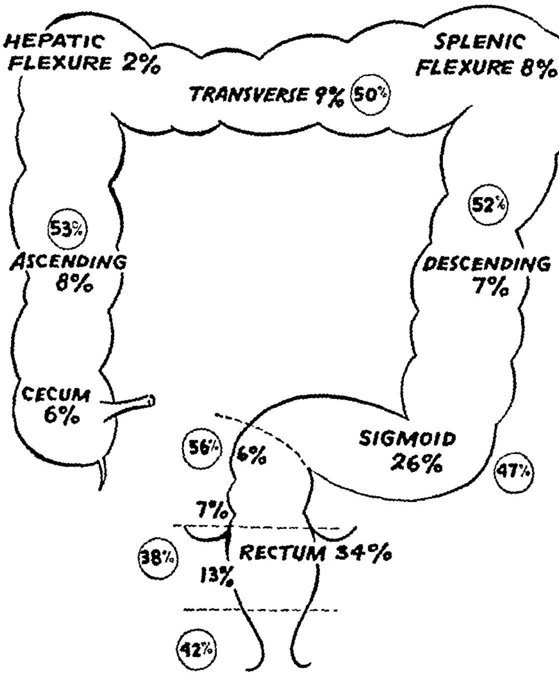

Fig. 1.—Distribution of carcinomas believed to be potentially curable. Percentages shown in circles indicate five-year survival rates of persons who underwent curative resections.

Definition of Terms.—The term anterior resection was reserved for those resections of the sigmoid flexure or rectum in which the superior hemorrhoidal artery was ligated proximal to at least one sigmoidal branch. If a less radical procedure was carried out the operation was labeled segmental resection. The term palliative resection was used whenever the surgeon, in his opinion, had left grossly visible or palpable cancer in the body of the patient at the conclusion of the surgical procedure. The term resection for cure, or curable lesion, was used whenever the surgeon, in his opinion, had removed all the grossly visible or palpable cancer from the body of the patient. The term five-year survival was applied to all patients alive longer than five years after operation whether free of disease or not. All patients lost to follow-up were regarded as dead.

Analysis of Records

The records of 623 patients who had been operated on were analyzed. Ninety-nine patients were subjected to various minimal palliative or first stage procedures. Hospital deaths occurred in 12 of those for whom a colostomy or cecostomy was established for relief of obstruction and for whom a second stage curative procedure had been planned. Palliative resections were carried out for 88 patients, leaving 436 patients for whom definitive resection for cure was possible. Of these patients, 23 died in the immediate postoperative period. Of this entire group, 213 were alive more than five years after resection.

Since in this survey we were dealing only with patients who had been operated on, we have no reliable criterion by which to judge operability. It should be pointed out, however, that in a similar survey of the Syracuse Medical Center the operability of cancer of the colon in about the same period of study was 96%. Resection of the primary lesion was thought to be desirable for 84% of the patients in this entire series subjected to exploration. Resection for cure was possible in 70% of the entire group. The five-year survival rate was 35% for all patients operated on, 41% for all patients in whom resection was carried out, and 51% for all patients leaving the hospital after resection for cure.

The distribution of single carcinomas believed potentially curable in the various segments of the colon is shown in figure 1. It can be seen that in this series only 34% of lesions were found in the rectum and only 21% in the extraperitoneal portion of the rectum. In 13 patients multiple carcinomas were found at the time of surgery and in 9 patients a second carcinoma of the colon developed subsequently in the period under study. Thus multiple *carcinoma developed in 5% of all patients, 3%* being synchronous and 2% metachronous.

The average age in this series was 62 years, somewhat older than in most series reported from some of the major clinics. The peak incidence by age was in the seventh decade. Females predominated in this group (270 to 254). Private patients outnumbered the ward patients about five to one in all age groups, with the exception that in the ninth decade the distribution was approximately equal.

Anemia.—Anemia severe enough to be manifested by a hemoglobin level of 11 Gm. or less per 100 cc. of blood occurred in 70 of 436 patients who were subjected to resection for cure. The incidence of anemia was highest among patients who harbored lesions of the ascending colon and progressively decreased in patients with lesions of the transverse colon, splenic flexure, descending colon, sigmoid flexure, and rectum. In this series only 36% of the patients in whom a curative resection of the ascending colon had been carried out and less than 10% of the patients exhibiting similar lesions of the sigmoid flexure and rectum could be classed as anemic.

Palpable Mass.—A palpable mass was found in 70 patients among 270 with potentially curable lesions in the colon above the rectum. Since an additional 215 patients had lesions that could be felt rectally or visualized by sigmoidoscope (fig. 1), there was a total of 285 patients, or 65% of the entire group, whose lesions could be seen or felt. In the patients with lesions of the ascending and transverse colon, approximately 40% of the lesions could be palpated, whereas only 16% of those of the descending colon could be felt.

Complications and Mortality.—In table 1 we have made a careful listing of all complications and deaths. We also tried to determine the underlying causes for these unfortunate occurrences. Males showed an 8% mortality in contrast to 5% in females. The risk of operation progressively rose in each decade past the age of 60. It is noteworthy that 170 resections of the colon proper were carried out in patients under the age of 60 with no deaths. Venous and arterial thrombosis and their consequences accounted for one-third of all complications. Pulmonary emboli likewise accounted for one-third of all deaths.

Table 1.—*Complications and Mortality in Patients with Carcinoma of Colon and Rectum in Whom Resection Has Been Done*

Causes	Nonfatal	Fatal	Total
Thromboembolic			
Phlebitis	19	..	19
Pulmonary embolism	7	8	15
Mesenteric thrombosis	..	2	2
Portal venous thrombosis	..	1	1
Cerebral thrombosis	1	1	2
Total	27	12	39
Infectious			
Peritonitis and abscess	31	5	36
Fistula	17	..	17
Dehiscence	7	..	7
Total	55	5	60
Miscellaneous			
Obstruction	10	2	12
Pulmonary	9	2	11
Urinary	22	..	22
Cardiac	..	7	7
Shock	1	2	3
Transfusion reaction	5	1	6
Bleeding	..	2	2
Other	10	2	12
Total	57	18	75

The use of antibiotics was not effective in preventing all infectious complications, since peritonitis occurred in 8% of cases and accounted for one-fifth of all deaths. Anastomotic leakage with fistula formation occurred in 5% of all patients in whom intestinal continuity had been reestablished. Wound dehiscence was surprisingly infrequent, occurring in less than 1 in 50 patients. Urinary complications, usually retention, occurred to a significant degree in 4% of all patients, and most of these occurred after combined abdominoperineal resection. Obstruction of the small intestine was present in a total of 10 patients. In two of these it was the cause of death. Transfusion reactions occurred in five patients and proved fatal in one of these.

Table 2.—*Influence of Preparation of Intestine, Prior to Operation, on Infectious Complications in Patients with Carcinoma of Colon and Rectum*

Type of Preparation	Total Elective Cases	Abscesses and Fistulas	
		No.	%
Sulfonamides	215	17	8
Sulfonamides and broad-spectrum antibiotics	61	4	8
Broad-spectrum antibiotics	86	6	7
Cathartics and enemas	49	6	10
None	10	0	

Acute Obstruction and Mortality.—Six deaths after elective resection occurred among 68 patients who had survived decompressing procedures for acute obstruction. If we add to these the 12 patients who died after first stage cecostomy or colostomy and for whom a second stage definitive operation was planned, we find a total of 18 deaths among 80 patients, otherwise potentially curable, who were admitted to the hospital for acute obstruction of the colon. This gives a 22% over-all mortality in this group compared to 3.7% in the group not showing acute complete obstruction.

Preparation of Intestine.—In table 2 we have shown a comparison of the incidence of complications among patients in whom the intestine was unprepared, prepared with sulfonamides (usually succinylsulfathiazole [Sulfasuxidine]), or prepared with broad-spectrum antibiotics (usually oxytetracycline [Terramycin]) or a combination of sulfonamides and broad-spectrum antibiotics. It can be seen that there was little difference in results when sulfonamides, broad-spectrum agents, or a combination of both was used. Infectious complications appeared to be only slightly more frequent when such preparation was omitted.

Closed Versus Open Anastomosis.—Although the closed technique anastomosis was not commonly used in this series, neither infectious complications nor fistula were reported in this particular group of 32 patients. However, one obstruction due to diaphragm formation did occur.

Combined Abdominoperineal Resections Versus Anterior Resections.—There were 10 deaths, 9%, among 113 patients subjected to combined abdominoperineal resections for cure, whereas there were 4 deaths (3%) among 141 patients who underwent anterior or segmental resection for cancer of the upper part of the rectum and sigmoid flexure. That combined abdominoperineal resection is a serious operation, particularly in the elderly, is attested by an 18% mortality in those operated on in the eighth decade, an age group in which anterior resection carried but a 5% mortality.

Factors Influencing Five-Year Survival

Age.—In figure 2 we have charted the percentage of five-year survivors as well as the five-year expected mortality as predicted in the United States Life Tables of 1950 for the various age groups. The falling death rate from cancer with advancing years is overbalanced by a rising rate from other causes. Whereas at ages 30 to 39 the ratio of cancer deaths to those from other causes is about 20 to 1, it falls progressively to 6 to 1 at ages 40 to 49, 3 to 1 at ages 50 to 59, 5 to 4 at ages 60 to 69, and 1 to 2 at ages 70 to 79. It is perhaps somewhat due to patient selection that in the patients aged 80 to 89 the percentage of survival was as good in the operated group as in the general population.

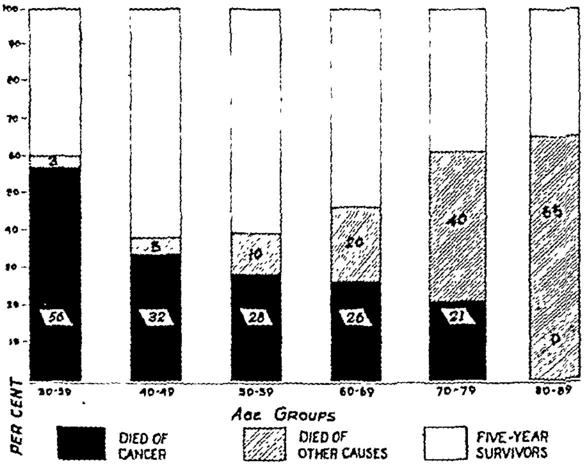

Fig. 2.—Influence of age on mortality from cancer in patients who underwent resection for cure.

Site of Lesion.—It is shown in figure 1 that there is relatively little difference in survival rate according to site except that a poor prognosis is evident for patients in whom the extraperitoneal portion of the rectum is involved. The five-year survival rates were 40% for patients with involvement of the extraperitoneal portion of the rectum, 47% for the sigmoid flexure, 52% for the descending colon and the splenic flexure, 50% for the transverse colon, and 53% for the ascending colon.

Anemia.—The five-year survival of anemic patients who at operation had a curable lesion was not particularly different than the cure rate for the entire group. It is even possibly significant that the cure rate for curable cancer of the ascending colon in the presence of anemia was considerably better than for the entire group—70% as compared to 53%. However, if we include all anemic patients we find that the over-all cure rate is somewhat worse for the entire group than with patients who did not suffer anemia. Analysis showed that 37% of patients who were anemic and had cancer of the ascending colon survived the five-year period, whereas 33% of all nonanemic patients with lesions at the same location survived the five-year period. This includes all patients. Prognosis for patients with such lesions involving the descending colon was somewhat worse but not hopeless—25% as compared to 35%. Anemia, however, in the presence of a carcinoma of the rectum was a particularly bad prognostic sign, since only one-sixth, or 16%, of these patients survived five years, whereas 40% who were not anemic survived this period.

Palpable Mass.—The five-year survival rate among patients harboring a cancer of the ascending colon whose lesions were palpable through the abdominal wall was equal to that found in the patients whose lesions were not felt (17 of 37). We regard palpation of such a lesion as a poor prognostic sign in the transverse colon, since only 5 of 22 patients with such palpable growths survived five years. The prognosis for patients having palpable lesions of the descending colon was not quite as good as those with lesions not felt (15 of 35) but was much better than for those in whom lesions of the transverse colon were felt.

Acute Obstruction.—Acute intestinal obstruction for many years has been regarded as a poor prognostic feature in association with carcinoma of the colon. If we consider only patients operated on for cure, the survival rate of 35% among patients with obstruction is compared to 54% for all other patients for whom resection for cure was carried out. If we consider all patients originally operated on, the cure rates are 25 and 36% respectively. Analysis of these patients' records for other serious prognostic features showed there was not a higher incidence of lymph node metastasis, serosal extension, or local fixation than in the remainder of the group.

Perforation.—In 24 patients gross perforation of cancer had occurred. Eighteen resections were regarded as curative and six for palliation only. Three deaths occurred among eight patients for whom emergency resection was carried out. Rather surprisingly, 5 of these 18 patients subjected to so-called curative resection in the presence of frank perforation of the colon survived the five-year period.

Local Fixation.—Local fixation of a lesion to a locally resectable site was not necessarily a bad prognostic sign. Among 20 patients whose lesions were in the ascending colon, splenic flexure, or the descending colon, there were 13 five-year survivors when resection was carried out with a view to cure. There were 7 survivors among 19 whose lesions were in the sigmoid flexure. However there were but 2 survivors among 18 patients with fixed cancer of the rectum. It is apparent from these figures that the prognosis is not necessarily bad if one is capable of removing en bloc the carcinoma with its zone of contiguous spread, such as is usually possible in cancer of the intestine involving either flank.

Scrosal Extension.—There was surprising little difference in survival rate between the group of patients whose lesions showed serosal extension (48%) and those whose lesions had not broken through the full thickness of the intestinal wall (54%).

Microscopic Grade.—A relatively small percentage of the growths in this series were graded according to Broders' index. This fact has prevented a fully accurate report of the effect of this factor on five-year survival in this series. However, of 149 patients whose carcinomas were graded 1 or 2 according to Broders' classification, there were 76 five-year survivors (51%), whereas there were 24 survivors (40%) among the 59 patients whose lesions were of high grade 3 or 4. Patients with mucin producing carcinomas showed a 32% five-year survival, whereas there were 99 survivors of the 161 (61%) patients whose lesions were ungraded.

Nodal Metastases.—The absence of nodal metastases was a reasonably good sign for patients with lesions at all levels. The presence of lymph node metastases offered only a slightly poorer prognosis for the colon, being 43% for the ascending colon and 45% for the remainder of the colon proper, but was of serious portent in the presence of cancer of the rectum. Only 26% of patients with rectal lesions survived the five-year period.

Combined Abdominoperineal Resection Versus Anterior Resection

Although combined abdominoperineal resection was rather infrequently carried out for lesions of the upper part of the rectum in this series, certain comparisons can be made with anterior resection. The five-year survival rates applied to lesions at identical levels, 9 to 15 cm., were approximately equal. A breakdown of the cases as to the presence of lymph node metastases showed little difference. Similarly, the distribution of the lesions with serosal spread was practically identical between those operated on by either method. There were 23 five-year survivors among the 45 patients submitted to anterior resection and 12 five-year survivors among the 25 patients subjected to combined abdominoperineal resection. All that we can state is that in this series there was no demonstrable superiority for either operation in terms of five-year survival. As we have shown previously, the mortality after combined abdominoperineal resection was approximately three times as great.

Comment

We believe this survey is unique in that cases from many surgeons from small and relatively large cities are included. Some of these surgeons work in teaching centers, others have no house staff. We believe the case material studied is representative of not only the true picture of colon cancer as seen in this part of New York state but also the current standards of surgical treatment of this disease in this area. The incidence, by site, sex, and age, is undoubtedly accurate. The operability and curability are in close agreement with other reports.

Hospital complications and causes of death have changed since the advent of antibiotics. Whereas peritonitis still is a serious problem, vascular complications, both venous and arterial, have assumed a major roll in morbidity and mortality.

Acute obstruction still appears to be the complication of cancer most likely to end fatally. When we consider that well over 60% of the patients who entered the hospital because of acute intestinal obstruction had had clear-cut intestinal symptoms for more than three months, we realize that much of this mortality could have been avoided by more prompt diagnosis. There is some factor about obstruction which not only is more apt to be more immediately lethal but, if the patient survives the initial obstructive episode, appears to increase the possibility of metastasis. Possibly the enormous pressures built up in the intestine force cancer cells in increasing numbers into the blood stream, although to our knowledge there is no proof of this theory. Certainly we all know that cancer cells are often pushed in the blood stream in the course of operative manipulation, and it would appear that the pressures built up in the colon in the course of the acute obstruction of the large intestine would be many times that produced by the surgeon in the ordinary surgical procedure.

From the results of this study we can hold no brief for a specific type of preoperative preparation except to state that the nonabsorbable sulfonamides and the broad-spectrum antibiotics either alone or used in combination did not always prevent infection. There seemed to be slightly fewer complications in the patient whose intestine was thus prepared than in those in whom no preoperative chemotherapy or antibiotic was used, although the differences were not great. Possibly some of the newer types of preparations, the combination of sulfonamides and neomycin sulfate, may in fact be superior to those which were used during this period.

Anemia in this series was slightly less common than in other series reported, especially when considering cancer of the ascending colon. These lesions were diagnosed somewhat earlier, anemias had been treated, or our criterion for anemia was slightly more strict than that used in some other series. The presence of anemia did not appear to unfavorably affect prognosis except in cases of cancer of the transverse colon and rectum.

An abdominal mass was palpated in approximately 30% of patients whose disease was in the body of the colon. As in anemia, the presence of the mass did not influence the prognosis except with lesions of the transverse colon and the sigmoid flexure.

We tried very carefully in this series to assay the comparative results of combined abdominoperineal resection and anterior resection when applied to patients suffering from carcinoma of the upper part of the rectum from 10 to 15 cm. As far as we could determine, the prognosis was equal. The morbidity and mortality of combined abdominoperineal resection was considerably greater, particularly when the operation was carried out on the elderly; the over-all mortality of combined abdominoperineal resection was 9% and, of anterior resection, 3%; in patients past the ages of 70 the figures were 18 and 5% respectively. The facts speak for themselves. It would appear that if 3 in. of normal intestine can be removed distal to the lower border of the lesion and if the middle hemorrhoidal pedicles are included in the specimen, anterior resection should be the procedure of choice for lesions involving the colon from 10 to 15 cm. It is noteworthy that in 74% of all patients in this series continuity of the intestine was restored without loss of sphincteric action.

Summary and Conclusions

Case records of 623 treated patients suffering from cancer of the colon and rectum were reviewed. Five-year survivals occurred in 35% of the entire series, in 41% of all patients whose growths were removed, and in 51% of all patients who left the hospital after resection for cure.

Thirty-four per cent of carcinomas were found in the rectum but only 21% of the entire group within the extraperitoneal portion of the rectum. Less than 50% of all malignancies could be felt or seen by the sigmoidoscope, but an additional 15% could be palpated through the abdominal wall. Thirty per cent of the carcinomas of the colon proper could be felt transabdominally. The presence of an abdominal mass involving either flank did not materially worsen the prognosis.

Anemia occurred less frequently in this series than usually reported. Only 36% of patients who suffered carcinoma of the ascending colon showed a low hemoglobin level. Anemia was not of serious prognostic import except in dealing with cancer of the transverse colon or the rectum.

There was a 22% operative mortality among the patients who entered the hospital because of acute intestinal obstruction and for whom curative resection was planned, as contrasted with a 3.7% mortality among all other patients who underwent resection for cure. Five-year survival, including hospital survival, was 35% in the obstructed group and 54% in the nonobstructed group. Preparation of the colon with either enteric sulfonamides or broad-spectrum antibiotics resulted in a slightly decreased incidence in infectious complications and fistula formation.

The mortality after combined abdominoperineal resection was three times that of anterior resection when applied to patients with lesions of the upper part of the rectum and sigmoid flexure, whereas the five-year survivals were not appreciably different.

A very important prognostic feature was age. The death rate from cancer in five years among the group in whom resection for cure was carried out progressively fell with each decade from 56% in the fourth decade to only 21% in the eighth decade.

Curable carcinoma of the ascending colon is not usually associated with anemia. The occurrence of anemia, the presence of abdominal mass, or local fixation does not unfavorably affect the prognosis except in patients with lesions of the transverse colon, sigmoid flexure, or rectum. Intestinal obstruction is the single greatest factor of bad portent in terms of both the operative and the long-term survival. Anterior resection, when technically feasible, should be the operation of choice for most lesions in the upper part of the rectum or lower part of the sigmoid flexure.

405 Medical Arts Bldg. (2) (Dr. Gregg).

FOODS STERILIZED BY GAMMA RADIATION.—In the Metabolic Ward of the Medical Nutrition Laboratory, studies with human volunteers of forty irradiated foods stored and frozen, and some stored at room temperature, have been completed. The volunteers have been checked by a battery of clinical tests, such as liver and kidney functions, blood counts, electrocardiograms, x-ray examinations, and determinations on the urine and feces. Follow-up examinations have also been accomplished after six and twelve months. To date, no evidence of toxic effects from consumption of irradiated foods has been revealed. There is no significant difference in metabolizable energy or digestibility between irradiated and non-irradiated foods. There is no consistent pattern as to acceptability of irradiated foods. Herbert Pollack, M.D., Wholesomeness of Irradiated Foods, *Journal of the American Dietetic Association*, March 1959.

THE CANDIDATE FOR CORONARY HEART DISEASE

DISCRIMINATING POWER OF BIOCHEMICAL HEREDITARY AND ANTHROPOMETRIC MEASUREMENTS

Menard M. Gertler, M.D., Max A. Woodbury, Ph.D., Lida G. Gottsch, M.D., Paul D. White, M.D.
and
Howard A. Rusk, M.D., New York

It is desirable to develop criteria with which to judge whether given persons or groups of persons are likely to have coronary heart disease later in life. The technique of discriminant function analysis of variance has been applied to data on 100 normotensive patients under the age of 40 with coronary heart disease and to 146 putatively normal subjects. The presence or absence of coronary heart disease was correlated with the logarithms of height and of total serum cholesterol, serum phospholipids, and serum uric acid levels and with four anthropometric indexes and familial incidence. The highest correlation was between coronary heart disease and total serum cholesterol level. There was a negative correlation with stature, the taller subjects being less likely to develop coronary heart disease. The correlations found have been combined in a multiple regression equation which has a measurable predictive value in groups of persons and promises to be useful as a research tool.

There is a growing interest in the relationship between certain biological characteristics and proneness to cardiovascular disease.[1] Such a relationship, when it can be clearly established, could be very useful for predictive purposes. Considerable preliminary work has to be done, however, before predictive experiments can be designed. In developing some means for preselecting "normal" persons for detailed study, it is difficult to establish what is to be considered normal because it is apparent that many presumably healthy persons are incubating chronic cardiovascular disease.

Enormous strides have been made in controlling the acute infectious diseases because of the success of epidemiologic studies coupled with the advances in therapeutics. One of the consequences of an effective program in controlling the acute infectious diseases is the rise of the age at death in the American population from 45 years of age in 1900 to 73 years of age in 1957.[2] The rise in longevity in the American population has contributed to a large extent to the rise in mortality and morbidity due to cardiovascular disease, cancer, and arthritis. Along with this greater longevity, the entire population will increase from 170 million in 1956 to 225 million in 1980.[2] Thus, the population not only will increase in actual numbers but will be an older population. It has been calculated that, in 1900, only 13.6% of the population was over 45 years of age while, in 1980, according to estimates, 43% of the population will be over 45 years of age.[2] Accordingly, the problem of chronic disease will become of increasing importance and major concern.

There is no doubt that the successful prevention of coronary heart disease will begin by recognition of the disease in its incipient form and delay of the onset of the disease by preventive measures. In 1951, a report by Gertler, Garn, and White [1a] suggested the possibility of preselecting from putatively healthy persons those who may be candidates for coronary heart disease. This method of preselection was based on the presence of a combination of factors in a healthy, noncoronary group similar to those observed in a coronary heart disease group. Shortly after this communication was published, other workers attempted to predict proneness to coronary heart disease by elevation of levels of serum lipoproteins in conjunction with blood pressure [1b] or by a combination of serum cholesterol level, blood pressure, and weight.[1c] These latter two methods of preselection have demonstrated that, by a critical assemblage of the variables mentioned, a better measure is obtained of the person as a candidate for coronary heart disease. These methods do not include such important measurements as height in relationship to weight, body build, heredity (mother, father, and siblings), and levels of individual lipids (cholesterol, lipid phosphorus). It is, therefore, reasonable to suggest that by including additional variables which are known to differ significantly in a normal healthy group and a proved coronary disease group a higher degree of discrimination of potential candidates for coronary heart disease will be possible. It should be emphasized at this juncture that, as additional criteria are uncovered, the possibility of such discrimination for the person will be greater.

A preliminary statistical study undertaken in conjunction with the statistical division of the International Business Machines Corporation Service Bureau indicated that the technique of discriminant function analysis of variance with use of an electronic computer would be valuable in "correlating" and "weighing" the individual characteristics from the normal group so that they might form the basis of preselection individually with a very high degree of discrimination.

From the Institute of Physical Medicine and Rehabilitation, New York University College of Medicine.

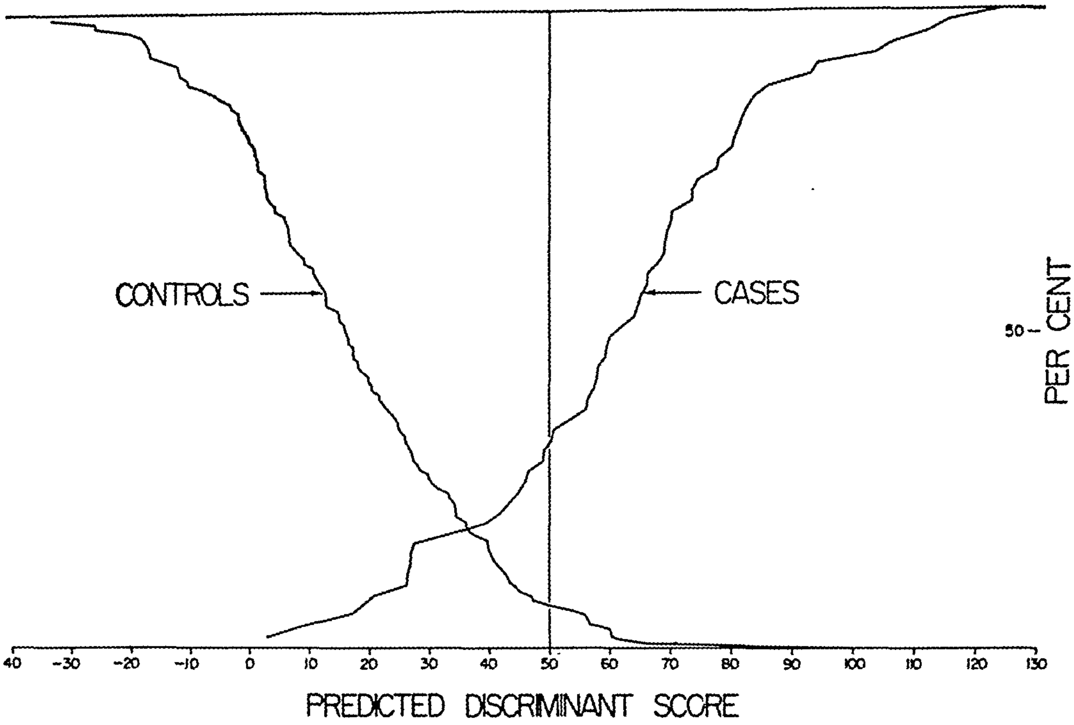
Methods, Materials, and Techniques for Analysis

Considerable data have accumulated in recent years to indicate a relationship of various specific factors to cardiac disease. By means of such relatively simple statistical procedures as the "t" and "F" tests, it is possible to show significant associations between specific factors and heart disease, e. g., serum cholesterol level and coronary heart disease. On other suspected factors, data continue to accumulate but positive correlations have not yet been established. It remains to effect some way to determine where an unknown, i. e., an individual, fits in relationship to the probability of having or not having heart disease. In other words, it is desirable to make some discrimination between persons or groups as to whether coronary disease may or may not occur in advance of the onset of the disease.

If, for example, the total cholesterol level for the diseased group and the controls is examined, it is found that the diseased group has the higher total cholesterol level on the average but that there is considerable overlap. Similarly, the two groups differ with respect to several other variables. Each of the variables will furnish poor material for discrimination, but a combined score may well be much better. The question of which particular combination to use to best discriminate the two groups has been subjected to precise quantitative evaluation. The resulting methodology was shown by Fisher[3] to be equivalent to the use of the multiple regression equation obtained when the variable to be predicted (the dependent variable) is chosen to be, say, 0 for one of the groups (here the control group) and 100 for the other group (here the coronary heart disease group). The predicting (independent) variables are the biochemical, genetic, and other factors which could be measured prior to the overt manifestation of the disease, for example, the total serum cholesterol level mentioned above.

The selection, composition, and type of studies conducted on the coronary heart disease group and the control group have been described in great detail elsewhere.[1d] The multiple regression equation used here as a discriminator is based on the original findings in these two series of persons.

In the initial study, a discriminant analysis of the data was made with use of the following variables to calculate a score which would best distinguish between control cases and disease cases: height, weight, ponderal index (height over cube root of weight), total serum cholesterol level, ratio of total cholesterol and phospholipids levels, ratio of total cholesterol, serum uric acid, and phospholipids levels, endomorphic index, mesomorphic index, ectomorphic index, and presence of coronary heart disease in mother, father, and sibling(s).



Percentage of cases and normals misclassified as function of discriminant score. Cases are plotted from left to right and controls from right to left for facility in indicating percentage of misclassification.

The resulting discrimination was good, but it was believed that an improved analysis should be made by transforming the biochemical and physical measurements to logarithms. In this form the various ratios could be replaced by the original variables. In the initial analysis there was a larger dispersion of discriminant scores within the coronary group than within the control group. It was expected, and such proved to be the case, that this heterogeneity would be corrected in the second analysis, performed by the computing laboratory of the New York University College of Engineering, Research Division.

In order to delineate better the principle used to obtain the discriminant scores, it may be worthwhile to note that the weights on the various contributing scores in the discriminating combination are so chosen to make the variation of the scores within the diseased group and within the control group as small as possible while keeping the difference between the groups large. There is, naturally, some dispersion of the discriminant score, but high values are associated with persons with coronary disease and low scores with control subjects. A dividing point of 37 on the discriminant score (see figure)—which does not involve the dependent variable but which might help predict it in advance of the onset of the disease—correctly classified 81% of both groups. Thus, 81% of those with coronary disease had a score above 37 while only 19% of the controls were found to have such a score, and 81% of the controls had a score below 37 while only 19% of those with coronary heart disease scored below this dividing point. If it were necessary to predict the proneness for coronary heart disease of every "unknown," it would be possible to classify about 81% of the subjects correctly. If one limits the scores to above 87 or below 0, it is possible to classify over 98% of the selected persons correctly. About 12.5% of those with coronary disease and 12.5% of the controls fall within these ranges, thus permitting a modest percentage of the entire population to be classified with a great degree of certainty.

Results

One hundred patients with well-documented "pure" coronary heart disease and 146 control (putatively normal) subjects in this series were first studied in 1947. Thirty-nine patients with coronary disease and 11 control subjects were not included in this discriminant analysis because data were incomplete. The means and standard deviations of all the variables included in this study were not affected sufficiently to alter the validity of this analysis by the absence of these data. By calculation of discriminant scores with various combinations of one or more independent variables, certain factors could immediately be eliminated from consideration. Thus, it was found that body weight was not a significant variable, although it is to be noted that this is under conditions of normal blood pressure. This bears out findings from a previous study.[4] Ponderal index was eliminated in favor of the significant portion of the index, i. e., height. Analyses to date (see table) indicate that the taller the subject is the less likely will coronary heart disease be present, i. e., a negative correlation. The mesomorphic index appears to be significant in the discrimination. This suggests that it may be a somatic indicator of the genetic type of person predisposed to coronary heart disease. Ectomorphic and endomorphic indexes and some of the "logical" combinations of the presence of coronary heart disease in parents and/or siblings were not found to be significant. When coronary heart disease appears in the family, it is more significant if both parents have it, with occurrence in father and sibling(s) or mother and sibling(s) of slightly lesser significance, as seen from the order in which they enter the step-wise regression. The ratios of cholesterol and phospholipids levels and total cholesterol, serum uric acid, and phospholipids levels were less effective as variables than the logs of each of the actual blood chemistry readings. Phospholipid level is also slightly negatively correlated, although there is a complex interaction between this factor and the serum cholesterol level, which shows a strong position significance. This has a biochemical bearing which is beyond the scope of this paper.[5] This relationship is expected to be the object of further study. Inclusion of blood uric acid level in the analysis does not improve the discriminant score to any great degree.

Comment

It is believed (based on preliminary studies, subsequent follow-up work, and confirmation by several groups) that coronary heart disease is a gradual process culminating in the overt symptomatology and only then recognizable. There were certain composite features of the coronary heart disease group which were occasionally found in subjects in the putatively normal group, i. e., body build, hereditary history, and serum lipids. It is reasonable to suggest that since coronary heart disease is a gradual process perhaps some of these covert characteristics may prove to be a clue to the underlying disease process and a future cardiac episode. Accurate individual prediction of the probability of experiencing coronary heart disease would make it possible to institute preventive measures to delay or forestall the initial coronary episode. This study is at present being expanded to increase the accuracy of individual prediction which will then make preventive therapy highly selective and realistic. It should be emphasized at this juncture that the present discriminating formula is to be used only for preselecting subjects for further study of characteristics of coronary heart disease and not for predicting the presence or absence of coronary heart disease in the individual case.

Summary

In a population such as exists in the United States today, where the acute infectious diseases are virtually controlled by advanced public health and chemotherapeutic procedures, there is a tendency toward the development of chronic diseases, especially those of cardiovascular origin. A recent study delineated certain characteristics common to both a control or putatively healthy group of men and a group of men who had experienced coronary heart disease. There appears to be a statistical relationship between proneness toward the disease and certain critical variables. Although this scheme of classification is useful in predicting the proneness to coronary heart disease in groups of persons, the formula will be used as a research tool to preselect persons for further clinical investigation in an attempt to delineate proneness to coronary heart disease in biochemical terms.

WHY ARE MEN'S CORONARY ARTERIES SO SCLEROTIC?

William Dock, M.D., Brooklyn, N. Y.

Both genetic and dietary factors are discernible in studies of the cause of coronary atherosclerosis. There are individual variations in the extent of development of supportive and contractile structures in the intima; in addition, certain effects of race, sex, and environment appear. Especially striking is the appearance of cholesterol deposits during the first year of life and their subsequent disappearance, alike in rabbits and in children, after weaning. The rate of infiltration decreases in childhood and is accelerated at adolescence in men and after the third decade in women. These considerations, with other results of recent investigations, indicate that the most important factors in coronary disease are nutritional and metabolic and that the greatest fault lies in the masculine love for rich food, alcohol, and tobacco.

Soldiers who have died of coronary disease have shown a striking predisposition to atheromatosis in the large arteries lying in the epicardium, since most of these young men had no other visible atheromas.[1] That this predisposition had an anatomic basis was apparent from the descriptions of the peculiar intimal supports recorded by histologists long ago. These spiral or longitudinal intimal bands, with longitudinal muscle and abundant ground substance, collagen, and elastic fibers, are found in the coronary arteries of many mammals and birds and are present before birth. Individual variation in the extent of development of these structures is great, and it has been suggested that part of the familial susceptibility to coronary disease may be due to familial variations in this anatomic predisposition to local accumulation of lipid as well as in metabolic or dietary factors which would affect over-all arteriosclerosis.[2] It also was noted, and has

Read before the Section on Pathology and Physiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

since been confirmed, that from birth onward males have thicker and *more extensive intimal* cushions than females.[3]

Comparative Incidence

That men suffer from angina and die from coronary disease earlier in life than women has been obvious to all students of these disorders for 186 years. For *almost* as many years, pathologists have noted that aortic atherosclerosis is slightly more marked, at any age, in women than in men. During the past decade it was shown that estrogens, in chickens, modify the pattern of plasma lipids and decrease coronary but not aortic atherosclerosis.[4] In men they also decrease and androgens increase *the fraction of cholesterol* bound to beta *lipoprotein*. It is this fraction, poorer in phosphorus and lecithin and less dense than alpha lipoprotein, which is found in elevated levels in animals developing atheromas on diets enriched with cholesterol and saturated fatty acids. Its level is also higher in victims of coronary disease than in controls of the same age and sex, that is, in persons in whom the evidence of atherosclerosis has not become manifest. On the basis of such observations, and one report on a great decrease in coronary sclerosis in patients with prostatic cancer who had had more than three months of estrogen therapy, several large studies of estrogen administration in coronary disease are now under way. The review by Oliver and Boyd[6] of 50 such patients, carefully matched with alternate controls and all selected three months after their first infarction, shows no difference in the total of fresh coronary occlusions and coronary deaths after 30 months, when 14% of them were dead and 14% more had survived second infarctions.

Another factor of great importance in sclerosis of the coronary arteries is thrombosis. Most American workers consider this as secondary to ulceration of atheromas, but Duguid and Robertson[7] and other British authorities regard the atheromas of men as organized and degenerated thrombi. These pathologists see no relationship between human arterial disease and the lesions evoked in rabbits, chickens, and monkeys by diets enriched with the lipids which are abundant in the foods enjoyed by prosperous people prone to coronary disease. In any event, a sex difference in mast cells which produce heparin[8] and sex differences in blood coagulability of men and women, as well as of patients with coronary disease as compared to controls,[9] may prove to be additional factors in explaining the epidemiology of myocardial infarction. Since one-third to three-fourths of the Americans who died from this disease, and whose cases were studied in various institutions, had no recent thrombosis, it seems unlikely that much of the sex difference can be due to difference in coagulability.

Two relatively recent studies have put the whole question of masculine predisposition to coronary disease in an entirely new light. One is the report of Keil and McVay[10] showing that in Atlanta, Ga., 37% of the new cases of coronary disease in Negro women occurred before the age of 50 and 66% before 60, while in Negro men the corresponding percentages were 22 and 48. In Caucasian patients at the same hospital only 7% of the cases in women occurred before the age of 50 and 21% before 60, while in Caucasian men the percentages were 14 and 38. Analysis of the material indicated that the reversal of sex difference in Negroes could not be explained by artificial menopause, hypertension, or obesity. In New Orleans[10A] it was noted that aortic atheromas increased rapidly during adolescence in Negro girls, as well as in both Negro and Caucasian males, but slowly in Caucasian females. Differences in estrogen and androgen production or metabolism may affect atherogenesis in females of these two races. Such a possibility is suggested by the report of Bauld and co-workers[11] that men with coronary disease given 17-beta-estradiol excreted more estriol than did control subjects.

At present, all that can be said is that Caucasian males everywhere, and Negro women in Atlanta, are prone to early onset of myocardial infarction as compared with the opposite sex of the same race. This may mean that there are racial differences in the anatomy of the coronary intima or in the effect of estrogens on coronary sclerosis which reverse the classic sex predisposition. It *may mean* that in some cultures diet, lack of physical activity, and the reaction to emotional stress predispose men, and in other cultures they predispose women, to develop infarction before the sixth decade.

Lober's[3a] study of coronary intimal infiltration from birth to old age in the Minneapolis population *provides equally surprising information (fig. 1)*. Here the rate of change in the intima was found to be greatest in the first year of life, confirming Bragdon's[12] observations on cholesterol deposition in the intima of suckling rabbits and the "suckling's cholesterosis," familiar to European students of human pathology. In rabbits and in children weaned from milk, these deposits vanish quickly. But in the Minneapolis population this infantile disorder is not outgrown, since the diet always contains milk and eggs. The rate of infiltration decreases in childhood and is accelerated at adolescence in men and after the third decade in women. Even in infancy and childhood infiltration is more marked in males. The rate of coronary intimal infiltration reaches its lowest level in girls 10 to 20 years old and more than doubles in males between the ages of 10 and 20, when androgen production and appetite for rich food are maximal. It then falls rapidly for a decade in men and more slowly thereafter, reaching the same level at 70 years as that at 10 years. Most of the decline after the age of 50 must be due to deaths from coronary disease eliminating those with advanced lesions from the entire population.

In girls the rate begins to rise only after the age of 15, and the peak, at 30, though lower than in males of 20, is slightly above that in males all through the fourth and later decades. There is no rise in the rate of infiltration in women at the time of the menopause. Lober's [3a] data show only a slower fall in elderly women than in men. It is the relatively high rate of infiltration of the intima prior to and in the decade after puberty that accounts for the greater sclerosis noted in Caucasian men as compared with women. The average infiltration rate in women 50 years of age is the same as that in men of 38. Lober's data show that, from the ages of 30 to 50, women form intimal deposits as fast or faster than men, in spite of the low androgen-estrogen ratio at that age.

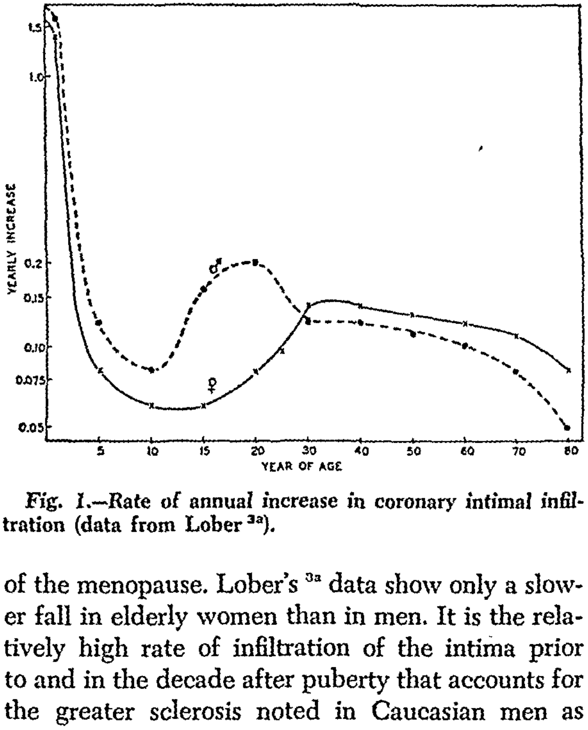

Fig. 1.—Rate of annual increase in coronary intimal infiltration (data from Lober [3a]).

Coronary atherosclerosis resembles the formation of sand bars in a river bed. In a large river, hundreds of feet of silt are deposited before there is any risk of a ship going aground. Lober's [3a] study shows that the coronary intima, averaging less than 10% of the whole arterial wall at birth, exceeds 50% in men 25 years of age and 70% in men dying of coronary disease. By the age of 30 the average man in Minneapolis was found to have coronary atherosclerosis that was 65% as severe as that of men who died of coronary disease at that age; by the age of 50 the average was 82% of the lethal degree of intimal infiltration. Of course these averages cover a wide range: a few men 50 years of age have scarcely any lipid infiltrations and others dying of accidents or tumor show greater total infiltration than men dead of coronary disease with small but strategically located lesions.

Women at the age of 50 have an average severity of coronary disease 90% as marked as men of that age and 70% as great as that of those who die of coronary disease. Since most of this disease in women developed between the ages of 25 and 50, when estrogen production was high, it is obvious that femininity only confers protection to modest degree even in Caucasian women; it increases the risk for Negro women in Atlanta. Th data supplied by the pathologists lend little support to the idea that suppression of androgen and high levels of estrogens will prevent progres of coronary sclerosis.

Early Development of Disease

The evidence from Minnesota that coronary disease makes great progress in the first two decade of life confirms the findings from studies of American soldiers killed in Korea.[13] Half of the American (average age 22 years) had atherosclerotic plaque in the coronary arteries, and 10% had the lume of one major branch reduced by more than 50% Enemy soldiers and young Japanese men had n *lipid deposits and no atherosclerosis.* It is to b emphasized that these Orientals were vigorou young men who fought well, and their arterie showed the intimal supports normal to all huma beings, with smooth muscle in abundant groun substance. They had survived two decades of wa and revolution and had been under stress far mor than the Americans. They had been accustome to long hours of physical labor but had had n milk products after infancy, little animal fat, an few eggs in their diets. This report, like so man others comparing poor Europeans, Orientals, Africans, or Latin Americans with prosperous North Americans, strongly suggests that men's arteries become sclerotic only when the diet would produce this lesion in a high percentage of men or women, chickens, rabbits, or monkeys. Sex difference in intimal structure or endocrine effects on lipid metabolism may explain in part why Caucasian women in North America have fatal coronary lesions 10 to 18 years after men. On the other hand, men, with higher metabolic rates, consume much more fat than women, and at puberty far more females than males restrict their diets. The period of high androgen levels and of rapid lipid infiltration of coronary intima coincides with a period when boys and young men have insatiable appetites for fatty food. Blood cholesterol levels are lower than later in life at this time of rapid atheroma formation.

Role of Diet

That the high rate of atherogenesis in adolescent boys and young men may be due largely to diet is suggested by the findings of Young and Pilcher[14] in a careful dietary survey in upstate New York in 1948 (fig. 2). There was almost no rise in the intake of calories, protein, and vitamin A by girls and women between 8 and 30 years of age. These findings disturbed the Cornell University investigators, for they show that, in spite of growth and weight gain, these girls and women held their food intake to levels which, in many, were below those regarded as minimal for good health.

On the other hand, in the males, the intake of calories, protein, and vitamin A rose sharply during adolescence. Vitamin A consumption, a good index of intake of egg yolk and butter fat, doubled between 7 and 15 years, falling rapidly between 15 and 20 and slowly thereafter to a level 25% above that in childhood. The rise in calories in adolescent boys was 40% and in protein 65%, with much less marked decline after maturity than that for vitamin A. While these sex differences in food consumption are undoubtedly dependent on androgen and estrogen, they show that the effect on diet may be more important than on lipid metabolism per se. This sex difference in diet was confirmed for Iowa adolescents by Eppright and Swanson in 1955.[15]

In man, there is rather striking evidence[16] that abuse of alcohol may cause hyperlipemia, thus hastening atherosclerosis and hypercoagulability, just as do diets rich in fat. Abuse of tobacco also appears to accelerate the fatal evolution of atheromas.[17] We have no information on the relative stresses or responses to stress in men and women, but there is no doubt that men still use alcohol and tobacco to excess far more than do women. Thus, the sex difference in age at death from coronary sclerosis may be due as much to external influences as to the differences in coronary intima or to the action of androgens on lipid metabolism or coagulation. This conclusion is in accordance with the fact that in 1772 Heberden's 100 patients with angina included 3 women, in 1896 Osler's series of 40 included only 1, and in 1957 Plotz' compilation of over 2,100 showed a ratio of 4 women to 17 men. If habits of either sex, rather than sex itself, were the decisive factor, the sex ratio would change as habits changed, with time, locality, or race.

Comment

What practical consequences can be drawn from this recent evidence of the relation of sex and other factors to early death from coronary disease? If, as one could have speculated five years ago, masculine vulnerability was due solely to inherent anatomic difference in the coronary intima or to the effect of the steroids which are essential for normal life, the prospects of doing anything would be hopeless. On the other hand, if these inherent factors merely accentuate the effects of exogenous influences which are essential to evoke any lesion, or are more potent than sex in accelerating its progress, the physician must do what he can to lay the facts before those who have, or have a high risk of developing, coronary disease. No one can be optimistic about easy success in persuading the obese patient to eat less, the patient with cirrhosis to drink less, or the patient with coronary disease to modify his usual way of eating, drinking, and smoking. Yet for those men who have heavy responsibilities and have had the intimation of swift mortality associated with heart disease it is not so difficult to make radical changes in their way of life. They often find it possible to adopt a regimen which does not interfere with work, play, or sexual activity and involves no outlay of money for drugs or laboratory tests. By

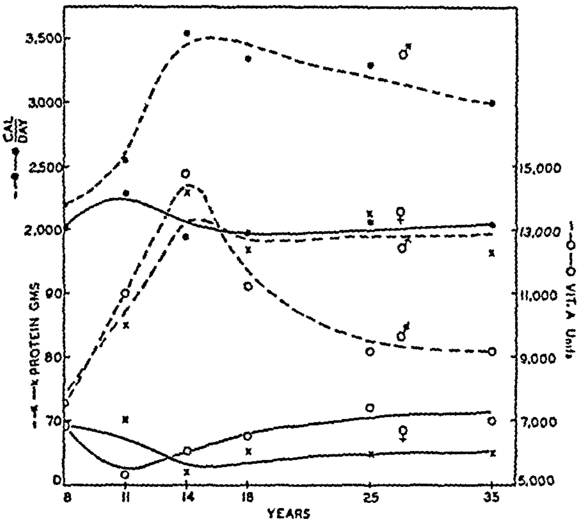

Fig. 2.—Daily food intake of adolescents (data from Young and Pilcher[14]).

merely avoiding eggs, milk products, and the visible fat on meat they avoid the diet associated with high rates of coronary disease. Fifty-two years ago Osler told his students that in treatment of many cases of coronary disease diet was the "central point." This has been amply borne out by recent research. Fourteen years later he reported that the largest contingent of his patients with angina were men "leading lives of high tension, who eat, drink, and smoke to excess." Perhaps this is still the best clue for those who seek to answer the question, "Why are men's coronary arteries so sclerotic?"

Conclusions

The coronary arteries lying in the epicardium have intimal supports of longitudinal muscle lying in a matrix of connective tissue. These structures, most evident near the branchings of the vessels, adapt them to the change in length in systole and diastole. They vary from person to person but are more developed in males than in females, even at birth. They probably explain the predilection of atherosclerosis for these vessels, since lipid accumulates in them, and they provide an anatomic basis for earlier lesions in males.

Androgens modify the plasma lipid pattern and perhaps also affect clearing factor and blood coagulability, thus aggravating the risk of coronary sclerosis and thrombosis in males.

The sex incidence of coronary disease, however, has markedly changed in the past 50 years; the incidence in Caucasian women has risen from 3 to nearly 20%, and in Negroes in Atlanta, Ga., deaths from coronary disease occur in women earlier in life than in men. This suggests that differences in eating, drinking, and smoking may be major factors in the sex difference in coronary disease. A great difference in eating habits of girls and boys at adolescence, when the masculine rate of atheroma formation is maximal, has been reported by dieticians. The high death rate from coronary disease in Caucasian men, at ages up to 60 years, can be accounted for entirely by the much higher rate of infiltration observed in males from birth to the age of 30. After that time, the rate of deposition of lipid in the intima is as fast in women as in men, but it takes 12 years to overcome the higher incidence gained by males during childhood and adolescence. Stress may precipitate coronary attacks and probably accelerates lipid deposition and coagulation of blood, but in those persons on diets low in animal fats stress does not cause atherosclerosis.

The fault lies not in sex but in the masculine love for rich food, alcohol, and tobacco that in our civilization men die chiefly from coronary disease. As Osler pointed out half a century ago, this is the "nemesis through which Nature exacts retributive justice for the transgression of her laws."

EFFECT OF ISONIAZID IN ANGINA PECTORIS

Elmer Pader, M.D.
and
Hyman Levy, M.D., New York

Isoniazid was administered over periods of three weeks to 20 patients who had been known to have angina pectoris for at least a year. The dosage was 300 mg. a day in three divided doses of 100 mg. each. The patients were instructed to continue taking nitroglycerin as needed, but all other coronary vasodilators were withdrawn. Ten patients completed the three-week course without decreased anginal pain or increased capacity for effort. Eight others did not complete the course, either because of disabling side-effects or because they saw no improvement. Only two patients felt better, and only one of these noted any return to his pretreatment state when he stopped taking the isoniazid. The dosage used in this series of patients, while sufficient to cause disturbing side-effects, appeared to have little value in the treatment of the anginal syndrome.

The recent reports[1] of the striking relief of anginal pain by iproniazid (1-isonicotinoyl-2-isopropylhydrazine phosphate) (Marsilid) have stimulated interest in the possible use of its less toxic analogue, isoniazid (isonicotinic acid hydrazide), for this purpose. A single report[1d] has described significant improvement in the anginal syndrome in one-third of patients treated with isoniazid. The purpose of the present study is to further evaluate the effect of isoniazid in angina pectoris.

Materials and Methods

The clinical material used in this study comprised 20 patients from an office practice devoted largely to cardiac disease. All of the patients had been known for at least one year, and in most of the patients angina pectoris due to coronary artery sclerosis had been present from 1 to 10 years. The diagnosis was established by the typical history of chest pain on effort. In all patients, the anginal syndrome was stable at the time of the study. Patients in whom serial electrocardiograms or history suggested acute coronary insufficiency or impending myocardial infarction were excluded. The patients ranged in age between 53 and 78 years, with 17 between the ages of 60 and 72. There were 15 males and 5 females, approximating the usual ratio of males to females with coronary artery disease in this age group. Three had significant hypertension and 17 were normotensive. Diabetes mellitus was present in two. Eight of the patients had sustained at least one previous myocardial infarction. Nitroglycerin requirement varied from occasional use to use as frequently as 35 times a day. The resting electrocardiogram taken prior to isoniazid therapy was abnormal in 13 patients, revealing evidence of previous myocardial infarction or of T-wave and S-T-segment deviations without evidence of previous infarction. A normal resting electrocardiogram was present in the remaining seven patients in whom the diagnosis was established by the classic history alone.

Isoniazid was administered in a dosage of 300 mg. a day in three divided doses of 100 mg. each for a period of three weeks. The patients were instructed to continue taking nitroglycerin as needed, but all other coronary vasodilators were withdrawn. Digitalis, diuretics, and other measures to control congestive heart failure were continued as indicated. On receiving the isoniazid, the patient was informed only that it was a drug found useful in some patients with angina, whereas it was not found beneficial in other such patients.

Evaluation of the effect of isoniazid was based purely on the subjective response of the patient with respect to change in the capacity for effort and the frequency of anginal attacks. If, by these criteria, improvement was noted at the completion of the three-week course of isoniazid, the drug therapy was continued for an additional three weeks. If improvement was sustained for six weeks, the drug therapy was then stopped to determine the effect of its withdrawal.

Results

Ten of the 20 patients completed the three-week course of isoniazid therapy but observed no improvement whatsoever in their anginal pain or capacity for effort. Four additional patients also found the drug to be ineffective but were com-

---

From the Department of Medicine, Mount Sinai Hospital.

pelled to stop the medication after only one to two weeks because of the occurrence of disturbing side-effects. One patient developed intensification of pain two days after starting isoniazid therapy and was found to have sustained a fresh myocardial infarction by electrocardiogram and clinical course. One patient noted no improvement in his anginal pattern after two weeks of isoniazid therapy and stopped taking the drug. Two patients noted slight improvement in anginal pain and slightly increased capacity for effort but were compelled to stop taking the drug because of unpleasant side-effects. One patient noted partial improvement in his anginal syndrome after three weeks of isoniazid therapy and the therapy was continued for an additional three weeks, during which the improvement was maintained. However, on discontinuation of the drug, he failed to notice any return to his pretreatment state. This is in marked contrast to the reported experience with iproniazid in which improvement persisted only as long as the therapy was continued, with recurrence of symptoms within days after discontinuing it. One must therefore consider the result in this patient equivocal at best. A single patient noted diminished frequency of pain and slightly increased capacity for effort which was maintained through six weeks of isoniazid therapy and which reverted to the pretreatment state when the therapy was stopped.

Side-effects.—Side-effects were observed in four patients (20%). Diarrhea occurred in two patients and nausea in two; one patient each developed dizziness, pyrosis, and generalized pruritus. The effect of isoniazid on the blood pressure was not impressive as compared to the reported effect of iproniazid in this respect. In seven patients a fall in the systolic pressure occurred; in four it was minor (10 to 20 mm. Hg) and in three moderate (over 20 mm. Hg). A minor fall in the diastolic pressure was noted in four patients (10 to 15 mm. Hg), but in none was there a marked fall. Neither syncope nor faintness while standing, suggestive of orthostatic hypotension, was encountered. Other side-effects, observed in patients receiving iproniazid, such as nervousness, impotence, paresthesias, difficulty with micturition, or evidence of hepatic dysfunction, were not observed in this series.

Effect on Electrocardiogram.—After the use of isoniazid, the resting electrocardiogram remained unchanged in 16 patients. In three patients minor T-wave changes, unassociated with S-T-segment deviations, were noted. The remaining patient developed the electrocardiographic pattern of acute anteroseptal myocardial infarction two days after starting isoniazid therapy. The causal relationship of the drug to this event cannot be ascertained.

Comment

Since the first published reports by Cesarman[2] and by Cossio[3] on the dramatic effect of iproniazid on anginal pain, other investigators[4] have confirmed their findings. Cesarman reported excellent results in all of 72 patients receiving iproniazid, and Cossio reported complete or almost complete remission in one-third of 120 patients and reduction in frequency, duration, and intensity of pain in another one-third. In Master's[1e] series of 74 patients 13 were completely relieved of angina, and in 28 patients angina was almost completely relieved. Towers and Wood[1f] described dramatic improvement in 17 of 40 patients treated with iproniazid and significant improvement in an additional 14.

Reports dealing with the use of isoniazid in angina pectoris are less numerous and the results less impressive. Cossio[1d] reported that one-sixth of 35 patients obtained complete or almost complete relief from isoniazid and significant improvement occurred in an additional one-sixth. Substitution of isoniazid for iproniazid provoked a recurrence of anginal pain in one-half of his patients, although he states that the pain was occasionally less frequent and less severe. Where isoniazid proved ineffectual in relieving anginal pain, the substitution of iproniazid for isoniazid resulted in subsidence of pain in one-half of these patients. In the study of Towers and Wood[1f] isoniazid was substituted for iproniazid in one patient and found to be ineffective. In the present series of 20 patients, using the same dosage of isoniazid as Cossio did (300 mg. daily), we found the drug to produce a significant, sustained improvement in a single patient only. An additional two patients who reported slight improvement were compelled to stop using the drug because of the occurrence of unpleasant side-effects. On the basis of this small series we concluded that isoniazid has little value in the treatment of angina pectoris.

The mechanism of action of iproniazid and isoniazid on the anginal syndrome is not as yet clear. Most investigators[5] feel that these drugs have no effect on the fundamental causes or natural history of coronary artery disease. Cesarman,[2] however, noting a correlation between subjective improvement on iproniazid and electrocardiographic improvement in many patients, believes that iproniazid has a direct action as well as a symptomatic one on the pathogenesis of angina pectoris.

Among the possible mechanisms of action proposed are (1) central nervous system stimulation with general elevation of mood and increase in the pain threshold [1e]; (2) a selective analgesic action on pain of ischemic origin, perhaps by selective block of the pain-producing "P substance" of Lewis [3]; (3) inhibition of monoamine oxidase causing an increased amount of catecholamines in the myocardium as well as an accumulation of serotonin in the brain, the latter resulting in central nervous system stimulation [6]; (4) inhibition of other enzymes involved in oxidative processes which either save oxygen or increase its utilization [1b]; and (5) increase in coronary flow, which has been demonstrated in vitro in the isolated, perfused cat and guinea pig heart.[6a]

In attempting to explain the relative ineffectiveness of isoniazid in angina pectoris by comparison with iproniazid, these differences in characteristics may be significant: Isoniazid produces much less central nervous system stimulation, elevation of mood, and euphoria than does iproniazid. Isoniazid is a relatively weak inhibitor of monoamine oxidase, producing a less marked rise in myocardial catecholamines than does iproniazid. Finally, using the perfused cat heart, Pletscher and Pellmont [6a] have demonstrated that *isoniazid definitely* has a lesser effect on coronary flow than iproniazid.

Side-effects

The occurrence of frequent and severe toxic effects due to iproniazid has tempered the earlier enthusiasm about the value of this drug in angina pectoris and prompted the evaluation of the less toxic isoniazid. In iproniazid-treated patients, hypotension, particularly in the *standing position*, has been noted frequently. Syncope with death,[1d] cerebral thrombosis,[7] *coronary artery occlusion*,[5] and coronary insufficiency with subendocardial necrosis [1e] have been observed. Faintness, weakness, and brief syncopal episodes have been described. Toxic hepatitis due to iproniazid, with jaundice, extensive hepatocellular necrosis, and sometimes death, is being reported with disturbing frequency.[8] Our own series shows that isoniazid, by comparison, is a significantly less toxic drug than iproniazid, and this confirms earlier findings.[9]

The effects of isoniazid on blood pressure were relatively insignificant and the deleterious effects due to a marked fall in blood pressure were therefore not observed. The side-effects encountered, although not serious, were sufficiently disturbing to limit the use even of isoniazid.

Summary and Conclusions

The effect of isoniazid in angina pectoris has been studied in 20 patients. In 16 patients (80%), isoniazid had no effect on the anginal syndrome; in 2 patients (10%) slight improvement in the capacity for effort was noted, but side-effects compelled discontinuation of the drug; in one patient (5%) an equivocal result was obtained; and in only one patient (5%) was sustained improvement noted while he was receiving isoniazid. The effect of isoniazid in relieving anginal pain is considerably less than the remarkable results reported for iproniazid. There are several possible explanations for this difference in effect. The side-effects of isoniazid are less frequent and considerably less serious than those reported for iproniazid. Isoniazid appears to be of little value in the treatment of the anginal syndrome.

INFLUENCE OF AIR CONDITIONING ON HOSPITALIZED PATIENTS

George E. Burch, M.D.
and
Nicholas DePasquale, M.D., New Orleans

A comparative study of circulatory and respiratory functions was carried out in 163 female hospital patients, 88 of them being in an air-conditioned ward while 75 were in a warm and humid ward affected by the outside weather. The numerical data were supplemented by systematic notes on appearance and behavior of the patients. Although the average age of the patients in the air-conditioned ward was five years greater, their mean systolic blood pressure was lower, pulse rate slower, and oral temperatures lower than those of the patients in the non-air-conditioned ward. Three cases are described in detail to show that in some situations the transfer from the warm, humid ward to the air-conditioned ward was decisive in bringing about the patient's recovery. A fourth case exemplifies the occasional unfavorable response to the change; there were nine instances of this. The possibility that the patient might benefit from an air-conditioned environment should be kept in mind, especially in cases of heart disease.

During the tropical New Orleans summers of 1957 and 1958, cardiac output and manifest work of the right and left ventricles were measured in a warm and humid ward and in a cool air-conditioned ward.[1] The cardiac output was greater in every patient in the warm and humid ward, the mean being 51% and the range 21 to 144%. In most instances the manifest work of one or both ventricles was also increased. The failure of manifested work to increase in some cases was due to an associated decline in pulmonary and/or systemic blood pressure. To obtain more general clinical information, including such less objective factors as comforts and psychological states, each patient was observed at the bedside and carefully questioned daily. This report presents the results of this study and emphasizes the benefits of air conditioning the environment of the ill or debilitated patient.

Material and Methods

All the patients were adult Negro females who were admitted on a rotational basis to adjacent air-conditioned or non-air-conditioned wards at the Charity Hospital, New Orleans. These studies were carried out from July 1 to Aug. 15 at the height of the tropical summer weather of 1957 and 1958. A total of 88 patients were studied on the air-conditioned ward and 75 patients on the open warm and humid ward exposed to the outside weather. The patients were seen twice daily, at 8 a. m. and 4 p. m. Blood pressure, pulse rate, respiration rate, and body temperature were recorded. General appearance was observed, with special attention to restlessness, irritability, sweating, and general well-being. The routinely recorded notes of the nurses, medical students, and various attending physicians were studied. Comments volunteered by the patients, observations of other clinicians, and comments from the nursing staff were also noted. The ward temperature and relative humidity were recorded daily at 8 a. m. and 4 p. m. with a sling psychrometer.

Results

Mean blood pressure, body temperature, pulse, and respiratory data are summarized in the table.

Air conditioning the environment of the hospitalized patient was found to be favorable in 71 patients, unfavorable in 9, and indifferent in 8. Favorable response was particularly evident in patients with congestive or coronary heart failure, bronchial asthma, and chronic diseases with debilitation. The following cases illustrate benefits of air conditioning.

Report of Cases

Case 1.—A 46-year-old female was admitted to the hospital on July 3, 1958, because of congestive heart failure associated with orthopnea, cyanosis, and anasarca, including edema of the face and arms. The patient had previously had cardiac catheterization studies and was found to have a bidirectional shunt through an atrial septal defect. She was admitted to the warm ward in a moribund state, too orthopneic to lie back even a few degrees and two dyspneic to talk. The blood pressure was 100/80 mm. Hg, pulse rate 110 per minute, respiration rate 28 per minute, and temperature 98.4 F (36.9 C).

The usual measures for the treatment of congestive heart failure were used, including phlebotomy, with only slight improvement. The patient remained restless, sweated profusely, complained of discomfort from the heat, and had continued tachy-

From the Department of Medicine, Tulane Medical School, and Charity Hospital of Louisiana.

cardia. On the third hospital day it was decided to transfer her to the air-conditioned ward. The improvement in the patient's condition within 24 hours was most impressive. This improvement continued; three days later she was able to lie almost horizontal, and within a week she was able to walk around the ward. Her pulse rate had slowed to 76 per minute, the venous pressure was 160 mm. H_2O, she lost 28 lb. (12.7 kg.), but the cyanosis was unaltered.

Comment.—For the three days that this patient remained on the warm and humid ward there was no improvement in her health. She was always drenched with perspiration, was extremely dyspneic and restless, and was apparently suffering from the heat. On transfer to the air-conditioned ward, the discomfort from the heat disappeared and sweating ceased. She felt better, was more comfortable, and was able to relax. There was a gradual and steady improvement in her health so that within one week she was able to walk with minimal difficulty. As was found in previous studies,[1] the cool and comfortable air-conditioned environment reduced the demands on her myocardium, thus reducing cardiac output and cardiac work so that her heart rested sufficiently to permit compensation.

Mean Clinical Data Obtained in Air-Conditioned and Non-Air-Conditioned Wards

Ward	Patients, No.	Determinations, No.	Mean Age, Yr.	Mean Blood Pressure, Mm. Hg	Mean Pulse Rate/Min.	Mean Respiratory Rate/Min.	Mean Temperature, F	Ward Temperature, F Day Mean	Ward Temperature, F Day Range	Ward Temperature, F Night Mean	Ward Temperature, F Night Range	Mean Relative Humidity, %
Air-conditioned	68	7,680	48	130/77	83.5	21.5	98.4	76	(71-76)	75	(72-76)	65.7
Non-air-conditioned	75	6,444	43	135/76	89.5	21.5	98.7	87	(90-79)	84	(80-88)	83.8

CASE 2.—A 25-year-old female was admitted to the hospital on July 31, 1958, because of status asthmaticus. The patient had been treated for approximately eight hours in the emergency room for severe bronchial asthma. Because of failure to respond to therapy and apparent suffering from the heat with marked sweating, restlessness, and irritability, she was admitted to the air-conditioned ward with the hope that she would benefit from the comfortable environment. The blood pressure was 110/80 mm. Hg, pulse rate 122 per minute, and temperature 100.8 F (38.2 C).

The patient was extremely tense and agitated. She was acutely dyspneic, and both lung fields contained wheezes and coarse rales. The patient arrived on the ward at 11 p. m. without alterations in therapy. She was asleep within two hours, and by morning she was no longer dyspneic, although a few rales remained in both lung fields. She stated that while in the warm and humid emergency room she felt "as if the walls were closing in around her," while on the cool ward breathing was easier and she was able to relax.

Comment.—Several factors probably influenced the improvement made by this patient when she was admitted to the air-conditioned ward. The calmness, thermal comfort, and quietness of the ward must have been conducive to psychological and physical relaxation, which decreased the demands for oxygen and breathing. The low humidity, as well as the lessening of allergens due to filters in the air ducts, may have removed the source of her difficulty. The benefits of the air-conditioned ward were dramatically displayed.

CASE 3.—A 38-year-old female was admitted to the air-conditioned ward on July 22, 1958, because of chronic renal disease, congestive heart failure, and mild uremia. Several years earlier she had had a nonfunctioning kidney removed, in an attempt to relieve her hypertension, without benefit. For several weeks prior to admission the patient noticed progressive dyspnea, swelling of the ankles, nausea, and vomiting. She was receiving 100 mg. of digitalis leaf daily. Blood pressure was 190/120 mm. Hg, pulse rate 102 per minute, respiration rate 38 per minute, and temperature 97.6 F (36.4 C).

The patient appeared to be a thin, chronically ill female who was in acute respiratory distress. Fine rales were present throughout the bases of both lung fields, and a loud harsh systolic murmur was audible at the apex. The heart was large, and venous pressure was 300 mm. H_2O. Digitalis therapy was continued, a mercurial diuretic was administered, and restriction of salt intake was begun. Within several days the patient was much improved. The venous pressure had declined to 120 mm. H_2O. The blood urea nitrogen level decreased from 68 mg. % on admission to 40 mg. % and remained at about this level for the remainder of her hospital stay. The nausea and vomiting gradually subsided, and the patient's appetite improved. She remained in hospital for one month, during which time she improved in health and gained in strength. No attempt was made to reduce her blood pressure at this time.

Comment.—This patient always appeared to be chronically ill and debilitated. She stated that her present difficulties began with the onset of the warm summer weather, when she began to feel uncomfortable, perspired a great deal, and became anorexic. She could no longer lie in bed and would sit in a chair all night near an open window fanning herself "for breath." After the first few days of treatment on the air-conditioned ward she no longer had such difficulties. She rested and slept well at night and on many occasions remarked that the coolness of the ward was responsible for her improvement and apparent well-being. A patient with little cardiac or renal reserve could develop failure of both of these organ systems under the stresses imposed by a hot and humid environment and improve when the environment stress is removed.

Unfavorable Response

While most patients were more comfortable and experienced improvement in their clinical course in the cool environment, this was not always true. An occasional patient complained that she "felt as if she had a cold." A few patients in congestive heart failure seemed to benefit from the cardiac rest afforded by the cool atmosphere in terms of a slower pulse and less dyspnea but complained of discomfort from the coolness of the ward and the inability "to get warm." Some patients were comfortable during the day but were too cool at night. Since it is not possible to regulate the environmental temperature and humidity to satisfy the differences in needs for comfort among patients, this was usually solved by providing blankets or sheets for covering. Nevertheless, an occasional patient did not tolerate the air-conditioned environment well.

Case 4.—A 31-year-old female was admitted to the hospital on July 1, 1958, for diagnostic studies because of a chronic pericardial effusion. The patient's symptoms consisted of mild shortness of breath and precordial pain. Venous pressure was 130 mm. H_2O, and the S-T segments were elevated in V_4, V_5, and V_6. Blood pressure was 120/85 mm. Hg, pulse rate 88 per minute, respiration rate 21 per minute, and temperature 99.2 F (37.4 C).

The patient complained of inability to keep warm and of a constant "stuffiness in her nose." Later she said that she had "caught cold" because of the air conditioning. She slept in a non-air-conditioned warm ward at night and sat in a non-air-conditioned solarium during a large part of the day. Her symptoms did not improve during the hospital stay.

Comment.—This type of reaction to an air-conditioned environment was unusual in the patients observed (only nine had an unfavorable response). It is perhaps surprising that more patients did not behave similarly, since the patients studied were indigenous to this area and acclimatization to the tropical weather was expected. However, in previous studies [1] no subject failed to demonstrate an increase in cardiac output when in a hot and humid environment, so that total acclimatization, at least in terms of cardiac output, must be the exception rather than the rule.

Comment

From the medical standpoint, a cool air-conditioned environment was beneficial to the invalid in large part because he slept more soundly, longer, and more restfully. The dyspneic patients found it easier to breathe, thus relieving anxiety and apprehension. Sweating with associated loss of fluid and electrolytes was eliminated as a clinical problem. The patients rested in bed more satisfactorily and were more coöperative and calm and less restless than on the warm ward. The management of atopic patients was improved probably in part because allergens were filtered out of the environment.

The elimination of sweating is an important factor in the management of the patient with congestive heart failure, for when it becomes necessary to maintain thermal equilibrium by sweating the cardiovascular system has been shown to be more actively at work.[2] Previous studies done at the Charity Hospital on 16 patients with congestive heart failure showed that severe dyspnea, rales, and gallop rhythm developed in all but 4 of these patients when they were exposed to a hot and humid environment (104 F and 85% relative humidity).[3]

Nursing was made easier by the cooler atmosphere of the air-conditioned ward. The suppression of perspiration produced comfort to the patients, nurses, maids, and all attendants and reduced objectionable odors. The quietness induced by the ward being closed was conducive to rest and relaxation. Linen remained clean longer and did not wrinkle readily, tending to prevent and improve the management of decubitus ulcers. The attitude of all personnel in contact with the patients was better; the general morale of all people in the ward was improved. The quiet, calm, and relatively peaceful nature of the air-conditioned ward increased the work efficiency of all those concerned with patient care.

The lack of statistical significance between the differences in blood pressure, pulse, and respiration of the patients on the two wards indicates the unreliability of these parameters in assessing the more subtle effects of air conditioning on the patient. Even in patients whose cardiac output was measured and found to increase, the pulse and respiratory rates did not change significantly.[1] In some patients one or both even increased in the cool environment. However, in individual patients the changes in vital signs noted for the cool and warm and humid environments were fairly large. This was particularly true in patients with heart disease (case 1). Therefore, it is necessary to individualize the influence of air conditioning for each person.

There were great contrasts between the two wards. For example, on the cool ward at 7 a. m. most patients were still asleep. They slept frequently during the day, and there was a general appearance of calm and quiet with outside noises reduced or eliminated. At the same time, on the warm ward at 7 a. m., most patients were sitting near their beds or walking around. Their skins appeared greasy and sweaty. Many had spent a restless night, sleeping for only short periods. Some complained that they were cooler and more comfortable at home.

The bed linen of many patients was damp with perspiration. On days when the temperature ranged between 80 F and 82 F and the relative humidity remained below 65%, most patients were fairly comfortable. However, during July and August in New Orleans such moderate temperature and relative humidity were rare.

Summary

At the Charity Hospital, New Orleans, 88 patients were studied on the air-conditioned ward and 75 patients on the open warm and humid ward exposed to the outside summer weather. Some of the less objective benefits of air conditioning the environment of the sick room, from both the medical and nursing points of view, were that air conditioning eliminated sweating, fostered a calm and quiet atmosphere, improved morale of both patients and attending personnel, removed allergens from the environment, and increased the tolerance of enforced bed rest. Most patients were greatly benefited by air conditioning, but the therapeutic results were not dramatic in all patients. There was a wide range of response of the patients, with the majority deriving benefit from the cool environment and only a few manifesting an unfavorable response. Air conditioning the environment of the sick room of a debilitated and chronically ill patient was found to be a useful adjunct to therapy which has not received the emphasis in medical literature that it deserves. This was particularly important for the patient with heart disease.

HEADACHES IN THE ANTARCTIC

Capt. Charles S. Mullin Jr. (MC), U. S. Navy

Headache is a frequent complaint at isolated antarctic bases. It was blamed in 50% of 37 sick call entries in this study. The medical officer found that few if any headaches could be attributed to eye strain, the cold, poor ventilation, sinus trouble, constipation, or similar factors. Interrogation indicated that headache was apparently related to the sharply felt need for careful control of aggression under circumstances of enforced close personal association. The headaches occurred more frequently in the civilian and officer group than in the enlisted group.

During two tours of American Antarctic International Geophysical Year installations in 1957-1958 in connection with a study of the adaptation of personnel to polar conditions, there was a seeming frequency of complaints of headache. Although headaches seemed common at most stations, one small base was selected for a close look at the problem. This isolated station was staffed by 12 civilian scientists and 12 military support personnel. Group morale was high. Some observations relative to the headache problem follow.

The sick bay log revealed only 37 entries for any cause during the 10-month period from the date on which the group became located there to the date of my visit. Of the 37 entries for any cause, 19 (50%) were for headaches described by the station medical officer as "severe." Eight men, one-fourth of the station complement, accounted for these 19 entries. Six of the eight were civilian scientists, that is, half of the civilian complement. The medical officer stated that entries were made for headaches only when the symptom was severe enough for him to suggest that the sufferer take time off from his duties and rest. He further stated that these headache entries represented only a fraction of the total number of headache complaints of personnel who made informal nonrecorded visits to sick bay for aspirin or other analgesics.

All the sufferers from severe headache had indicated that their headaches were in varying degrees more frequent and severe during their stay in the antarctic than before. Of the eight major sufferers, three said that they had had fairly frequent and sometimes severe headaches prior to their antarctic experience, and the others said that they had rarely experienced headaches.

There was insufficient time to obtain a detailed description of these headaches, but they appeared to present "vascular" and scalp muscle tension manifestations, with one man experiencing typical migraine. Cold was not a factor related to these headaches at this station (or others). Most of the headaches occurred during the winter months when there is comparatively little outside activity; in fact, most of the headaches were initiated and continued indoors. About one-third observed some relationship between their emotional state and occurrence or aggravation of headaches. The others were not aware of any such relationship and either could offer no explanation for their occurrence or gave explanations varying from general fatigue to eye strain, sinus trouble, and insomnia.

The station medical officer felt that few if any of these headaches could be attributed primarily to eye strain, poor ventilation, fatigue, cold, hunger, sinus trouble, constipation, or similar factors. The medical officer, who was also officer in charge of the station, said that all carbon monoxide detection devices were in order throughout the year and that he saw no reason to believe that low-grade carbon monoxide intoxication could have been a factor.

In addition to the more detailed investigation made at this station, the following observation was made at another isolated station the year before. At that station, of the 9 civilians and 4 officers attached, 6 complained of fairly frequent headaches, while of the 21 enlisted men whose records were available for review, only 3 complained of the symptom to the degree warranting an entry in the sick bay log.

Comment

These observations indicate a general frequency of headache at some stations in the antarctic, especially at the more isolated bases, and a tendency for this symptom to occur more prominently in the officer-civilian group. Psychological factors are probably important. A relationship often exists between controlled (repressed and suppressed) anger and the occurrence of this symptom. It is a striking fact, also, that at these small stations there was a remarkable absence of either physical fights or hostile-angry arguments. At the station on which this report is largely based, not one instance of fisticuffs occurred during the 10-month period and violent angry arguments were extremely rare.

When it is considered that the base comprised a group of young men of widely diverse background and interests, thrown together in enforced close personal association for a period of almost a year, the absence of such overt expression of hostility may seem astonishing. But a closer examination of the situation reveals the logic of this apparent tranquility. There was a conscious recognition of the necessity of control and of avoiding open breaks. Each man recognized that he was dependent on the goodwill of the "next man" and of the group as a whole in this "tight little world" for his own vital feelings of acceptance, security, and worth and that overtly expressed antagonisms represented too much risk when other sources of gratification of these needs were not available for an entire year. This abnormal control effort, whether it took the form of suppression, repression, distanciation, intellectualizing, philosophizing, or what not, could not be achieved without some cost in terms of accumulated tension.

The enlisted group were perhaps more fortunate in having more varied methods of handling the problem. For example, there was violent swearing (without, however, as much emotion as the content of their polemic would seem to call for), vigorous horseplay, loud but essentially good-natured complaining, and an interesting technique of exchanging frank and fearful insult, often quite personal and to the point but apparently rarely reacted to with much if any anger, as if there were a tacit mutual recognition of the function of the exchange. The more sophisticated scientist-officer group were more limited in the effective techniques available and were perhaps under greater self-imposed necessity for careful control of their aggressions: hence their preponderance of headaches.

Summary

Headaches are a frequent complaint at isolated antarctic bases and appear related to the sharply realized necessity for careful control of aggression under circumstances of enforced close personal association for a period of a year. These headaches occurred more frequently among the more sophisticated civilian and officer group, probably because of self-imposed higher level of restraint, as well as their inability to utilize certain techniques for dissipating their aggressions which were available to the enlisted group.

U. S. Naval Hospital, Philadelphia (45).

Lieut. Peter P. Ruseski, M. C., U. S. Navy, medical officer of the station studied, provided the information on which this report is based.

FUNCTION OF A METROPOLITAN CYTOLOGY LABORATORY

Douglas P. Graf, M.D., Cincinnati

Examination of cervical and vaginal smears for cytologic evidence of cancer has become frequent since its introduction in 1943. The number of examinations done in a single laboratory increased from 5,957 in 1950 to 27,602 in 1957. Follow-up studies have been possible on 1,044 women from whom vaginal smears were obtained in 1950. Experience has led to improved techniques and more reliable criteria for interpreting results. In one series the number of false-positives, judged by subsequent tissue studies, was 3.5% and the false-negatives 7%. Comparison of cytological results with other clinical and laboratory data has also been possible in 27,602 cases in a recent 12-month period; in this series a doubtful or positive smear led to the diagnosis of unsuspected uterine cancer in 77 cases. It is believed that the value of large-scale cytological screening of women by this technique is well demonstrated by the results here reported.

The publications of Papanicolaou,[1] Papanicolaou and Traut,[2] and Meigs and others[3] in the early and middle 1940's produced national interest in exfoliative cytology as an aid to the early diagnosis of cancer, particularly uterine cancer.

As a local manifestation of this interest a cytology laboratory was instituted at the Cincinnati General Hospital in 1947. Its sphere of activity was limited to patients of the Cincinnati General Hospital, and its personnel consisted of one house officer. After two years it was felt that the work of the laboratory was sufficiently promising to warrant extending its facilities to the practicing physicians of the community. Subsequent growth may be estimated from the steadily increasing volume of work.

For example, in 1950 there were 5,957 cervical and vaginal smears performed by the laboratory; in 1951, 7,789; in 1952, 9,268; in 1953, 12,730; in 1954, 12,499; in 1955, 14,259; in 1956, 20,822; and by 1957, 27,602. The purpose of this paper is to consider briefly the mechanics involved in the operation of such a laboratory, some of the problems encountered, and some of the results obtained.

Operation

At the present time the laboratory personnel consists of a physician, who serves as director and reviewing cytologist, and three technicians, whose duties include the staining and mounting of smears, the screening of these smears, and the large amount of secretarial work incidental to the function of the laboratory. We feel that this is the minimum number of technicians needed to handle the current work load and that a fourth technician will be necessary in the near future.

Interested physicians obtain mimeographed instruction sheets and request forms for cytological examination from the laboratory (see figure).

Equipment for taking the smears and fixative are supplied by the individual physician. The routine use of ground-glass "write-on" slides reduces identification difficulties and significantly lessens the time required to process smears. No direct recommendations are made as to the type or number of smears done on the individual patient. The trend, however, has been to the use of the Ayre spatula[4] in place of the bulb and pipet. This, too, has been helpful in expediting the work of the laboratory. Diagnosis in the case of a vaginal smear (made with bulb and pipet) may depend on only one or two cells. When abnormal cells are present in the cervical smear (made with the Ayre spatula), they are almost always present in abundance. It is argued that vaginal smears screen more potential cancer sites. As counter-argument it may be pointed out that while epidermoid carcinoma of the cervix uteri is a common lesion, adenocarcinoma of the cervix is uncommon, corpus carcinoma is very uncommon outside of specific age groups, and diagnosis of tubal or ovarian cancer by smear is rare. If the physician is particularly interested in screening these latter areas, an endocervical or caval aspiration may be used.

Smears are fixed in the physician's office for at least one-half hour and are then permitted to dry. Smears would be of better quality if kept wet from the time of fixation until staining; however, the practical advantages of drying, insofar as transportation and processing are concerned, outweigh the slight deterioration in slide quality. The bulk of smear slides reach the laboratory through the mail.

Smears, after being stained according to the Papanicolaou trichrome method, are mounted and screened by the laboratory technicians. Ink dots are used to mark questionable cells. It might be noted in passing that the use of wide-angle instead of standard ocular lenses permits a much larger microscopic field and therefore speeds the screening process.

From the Department of Surgery, Division of Gynecology, University of Cincinnati College of Medicine.

The smears are held for review by the cytologist if they (1) contain atypical cells of any kind; (2) are from patients with symptoms suggestive of carcinoma (e. g., intermenstrual bleeding); (3) are from patients concerning whom the attending physician has indicated some suggestion of cancer; or (4) are of any secretions originating outside the female genital tract.

Smears are categorized as negative, doubtful, or positive. No effort is made to identify the source of malignant cells or to distinguish between invasive and preinvasive carcinoma of the cervix. The cytologist may have an opinion about these things and often makes a private guess, but the ultimate decision must be left to the clinician and the pathologist. Rarely, unless asked, do we suggest a plan of study for the patient with a doubtful or positive smear. The clinician is in a better position to exercise such judgment than the cytologist.

In connection with the reporting of smears, it is of paramount importance that the laboratory firmly establish, in the minds of the clinicians to whom it is reporting, the limitations of the method. Hysterectomy done because of a positive genital smear and without biopsy confirmation, in a patient whose uterus contains no cancer, is a calamity always in the back of the cytologist's mind. Tantamount to this is the case of the woman who is subjected to hysterectomy under similar circumstances and whose cervix is subsequently found to contain grossly invasive carcinoma. Conversely, false-negative smears can lead a practitioner who does not understand the possibility of such reports into a do-nothing policy in the case of the patient with symptoms of genital carcinoma. The best way of avoiding these unpleasant occurrences is to discuss the technique in hospital staff meetings or over the telephone with physicians who have just started using the laboratory facilities. One specific safeguard used in our laboratory is the appendage to every negative report on a genital smear taken from a patient with postmenopausal bleeding of the following notation: "A negative smear in the postmenopausal bleeder does not rule out endometrial carcinoma." This is done because of the high incidence of endometrial carcinoma in patients with postmenopausal bleeding and the relatively higher incidence of false-negative smears in endometrial as opposed to cervical carcinoma.

It might be well, at this point, to consider some of the commoner causes of erroneous cytological diagnosis. Laboratory error may be divided into two main groups—negative error, in which the cytologist returns a negative report when the patient actually has a malignant lesion, and positive error, in which the cytologist returns a positive report and the patient has no demonstrable cancer. The clinician who understands the possibilities and sources of these errors is in a much better position to use the technique intelligently.

Factors in Negative Error

Misinterpretation.—To err is human, and the cytologist will make his share of interpretative mistakes. However, misinterpretation is not as common a source of negative error as might be expected. The finding of cellular atypia of any degree, if noted appropriately by the cytologist, will result in repeat smears and, if the changes are persistent, biopsy. When the pipet method is used faulty screening may miss the one or two abnormal cells on a slide, but when the Ayre spatula is used the abundance of atypical cells on the slide precludes this accident in practically all epidermoid cervical lesions.

Poor Choice of Application.—Theoretically study of the genital smear should, within the limits of its known accuracy, enable one to diagnose uterine cancer whether the latter is symptomatic or not. However, the major function of the smear is to arouse the suspicion of cancer where none previously existed; and when this has already been suggested by symptoms, the smear as a test for cancer no longer has a valid function. Poor choice of application means the use of the smear in cases in which other, more specific diagnostic measures are clearly warranted. The postmenopausal bleeder does not need a Papanicolaou smear, because her primary symptom has already suggested uterine cancer. In other words, the cytological technique is a screening technique and not one to be applied in lieu of specific diagnostic methods in the patient with symptoms.

Scanty or Poorly Prepared Smears.—The pathologist does not hesitate to return a report of "inadequate tissue for diagnosis." Such a decision is a little more difficult for the cytologist, because in the case of the scantiest smear he may accurately report that he has seen no malignant cells. It therefore becomes a matter of judgment as to when a smear is so scanty as to be inadequate, and occasionally the cytologist will make the mistake of reporting a scanty smear as negative when he should have returned no diagnosis and asked for a repeat smear. This is an easy trap to fall into, since the request of a repeat smear is a nuisance to the physician and the source, very often, of grave misgivings in the mind of the patient.

Many cytology laboratories, our own included, discourage the submission of bloody smears, and this policy has caused a certain amount of confusion in the minds of the clinicians. The structure of the greatest importance to the cytologist in his attempt to diagnose cancer by means of a smear is the nucleus. The primary advantage of the Papanicolaou trichrome stain is that it renders cytoplasm transparent and thus permits easy and accurate inspection of the nucleus. A frankly bloody smear loses this transparency and becomes, after staining, opaque. The cytologist, looking at such a smear, has the feeling that he is viewing cells through a muddy ocher filter. Nuclear detail is lost, and the cytologist is under a severe handicap. Small amounts of blood, on the other hand, as when the material being smeared is blood-streaked, present no obstacle to effective examination.

Other Errors.—A particularly humiliating source of error to the cytologist is superficial necrosis in an obvious, advanced carcinoma. Such necrosis results in poor detail in exfoliated cells and in some cases no cellular detail at all. If a negative report is returned under such circumstances the cytologist is sure to receive an indignant call from the attending physician who does not understand how the technique can miss obvious cancer and yet be expected to pick up very early lesions. The answer, again, is that, given an apparent lesion, the diagnostic choice should be biopsy, not smear.

Causes of Positive Error

Misinterpretation.—Cytological misinterpretation is by far the most frequent producer of false-positive smears in our laboratory. Certain benign cells, particularly degenerate endocervical cells, aberrant basal cells, and large histiocytes, may present nuclear alterations which can be confused with malignant changes. Careful observation, repeat smears, and experience are the only answers to such error.

Weakness in Cytological Technique.—A second cause of false-positive reports is a basic weakness in the cytological technique itself. Everyone is familiar with the nuclear abnormalities on which the cytologist depends for making a diagnosis of cancer—nuclear enlargements, increased nuclear:cytoplasmic ratio, irregular nuclear outline, hyperchromatism, and irregular deposition of chromatic material. However, it is also generally and vaguely believed that these changes are specific to malignant processes. This is incorrect. These changes are criteria, not of cancer per se, but of an increase in the rate of cellular division. Any process which increases the rate of cell growth can also produce nuclear atypia. The most striking examples of such nonmalignant atypia are found in genital smears taken from women who are pregnant or who are suffering from vaginitis. The cells in such smears may differ from truly malignant cells only in the degree of changes observed. Thus, the process of distinguishing the possibly malignant from the nonmalignant cell often becomes a problem not of distinguishing black from white but of evaluating intermediary shades of gray. This is a matter of cytological judgment, again, and therefore fallible.

Finding of Atypical Basal Cell Hyperplasia.—There is a process productive of false-positive reports which in my mind are not false-positive at all. Pathologists recognize a cervical lesion in which cellular changes, indistinguishable from preinvasive carcinoma of the cervix, occur but do not involve the full thickness of cervical epithelium. These cellular alterations affect the deeper cell layers but disappear in those layers nearest the epithelial surface. This lesion has been called atypical basal cell hyperplasia by most pathologists. Others, who feel that it represents a potentially malignant but reversible process, apply the term precancerous metaplasia.

When the Ayre spatula is used to obtain cervical cells for examination it may penetrate the superficial layers of normal cells and thereby pick up abnormal cells from more basal layers, leading to a positive report. Under these circumstances a positive report is returned on a patient who does not have cancer and must therefore be considered as falsely positive. On the other hand, the cells responsible for the diagnosis are morphologically indistinguishable from the cells which make up preinvasive carcinoma. This type of error leaves us unashamed.

False-Positive Findings Later Found Positive.—Finally, there are positive smears which cannot be substantiated at the time of initial investigation and are therefore deemed false but are eventually shown to be correct. The cancerous area exfoliating malignant cells may be so small as to be missed by punch biopsy. Such a tiny focus may also be missed by the pathologist if an insufficient number of blocks are made of an adequate amount of submitted tissue. And, rarely, the source of malignant cells found in a vaginal smear may be extrauterine, e. g., carcinoma cells from the bladder carried into the vagina at the time of urination.[5]

Effectiveness of Laboratory Screening

It is difficult to calibrate the effectiveness of a cytology laboratory, particularly one with a large work volume, in numerical figures. Usually when a report is made on the use of the cytological technique, an effort is made to determine the percentage of accuracy. Statistical reports in the national literature indicate the accuracy of the technique, as applied to the female genital tract, to be around 97%. This is not quite as impressive as might first appear. The 97% figure—indicating a total error of only 3%—is obtained by averaging out the positive error (that is, the number of positive reports returned in patients who did not have cancer) and the negative error (that is, the number of cases of cancer missed by smear). The positive error nationally is around 1% and the negative error around 10%. By averaging these two percentages together in relation to total patients screened, a total error of 3% is obtained. I think that this is medical sophistry. The most unpleasant thing that can happen to a patient with a false-positive report on a genital smear is an unnecessary cervical biopsy and/or dilation and curettage. A false-negative report, on the other hand, can contribute to the patient's death by cancer. The important figure, then, is the percentage of negative error.

Accurate figures concerning negative error[6] are difficult to obtain. A positive report calls for immediate investigation and, by that token, a positive error is usually detected quickly and reported to the laboratory. A negative error, however, is often not immediately apparent. Months or even years may elapse before an early occult lesion becomes overt. Determining negative error becomes a knotty problem, particularly when mass screening is in progress.

The following example may be used to show just how difficult this is. In 1955, an effort was made to determine the over-all accuracy of the cytology laboratory. We selected 1950 as the year for investigation, feeling that five years would, in the majority of instances, be sufficient time to permit cases of cryptic uterine cancer to become clinically evident. Lists of all patients screened in our laboratory that year, with dates and our reported diagnosis, were sent to all referring physicians with a column left blank for follow-up information.

A total of 5,609 vaginal smears were made in 1950. Of these, 357 necessitated subsequent tissue study (cervical biopsy or dilation and curettage). Physicians reported clinical follow-up studies of at least three years on 687 patients, which made a total of 1,044 women whose smear tests had been followed up. The incidence of positive error calculated from patients with subsequent tissue study was 3.5%. The incidence of negative error calculated from patients with subsequent tissue study was 7%. The incidence of negative error calculated from all patients with subsequent tissue study or clinical folow-up was 2%. The failure to obtain more follow-up data cannot be blamed entirely, or even in the majority of instances, on physicians. The greatest obstacle to compilation of adequate data was the patient who made only one or two visits and was subsequently lost to the original physician's surveillance.

In addition to the determination of percentage accuracy there is another perhaps more satisfactory way of estimating the efficacy of a screening technique. The basic, vital function of a cytology laboratory is the detection of cancer which would have been missed had it not been for the routine application of cytological technique. On the request form submitted with each smear is an item asking the physician to state (by check mark) whether or not he suspects cancer. In the event that the smear leads to a diagnosis of cancer and the above item has not been checked off, the physician is asked the same question by telephone. Only if the physician specifically denies any suspicion of cancer prior to the receipt of a doubtful or positive report is the patient included in the unsuspected list.

From Aug. 31, 1956, to Aug. 31, 1957, out of 21,200 patients screened, a doubtful or positive smear led to the diagnosis of unsuspected uterine cancer in 83 cases. From Aug. 31, 1957, to Aug 31, 1958, out of 27,602 cases screened, a doubtful or positive smear led to the diagnosis of unsuspected uterine cancer in 77 cases. Of these patients 49% had preinvasive carcinoma of the cervix, one of the few types of carcinoma in which permanent cure can be assured. It is my belief that these data strongly indicate the value of large-scale cytological screening of women for genital cancer.

APPARENT RECOVERY IN CHRONIC LYMPHOCYTIC LEUKEMIA

REPORT OF A CASE WITH FIVE-YEAR REMISSION AND NO CLINICAL OR HEMATOLOGICAL EVIDENCE OF THE DISEASE

Carl Reich, M.D., New York

A patient experienced sudden relief from the splenomegaly and other signs and symptoms of lymphatic leukemia and has remained free from all manifestations of the disease for more than five years. The onset occurred with rapid loss of weight in August, 1951, when the patient was 52 years old. Physical findings, hematological data, and results of lymph node biopsy were typical of chronic lymphatic leukemia. Treatment included repeated transfusions of whole blood, roentgenotherapy applied to the much enlarged spleen, and injections of liver extract. For two years the patient did not improve except temporarily after transfusions. The splenomegaly subsided abruptly in August, 1953, and when the patient was reexamined in September, 1953, her weight, appearance, blood cell count, and bone marrow were normal. They have remained so.

In most textbooks on medicine, leukemia is described as invariably fatal. A few patients have been reported who apparently recovered, but the diagnosis was usually doubtful and the reviewers[1] of these cases have always mentioned them with some reservations.

The case of lymphocytic (lymphatic) leukemia reported here occurred in a woman first seen by me in August, 1951. The diagnosis satisfied all the criteria of modern hematology, and the patient is alive and well today. A brief summary of the case history follows.

Report of a Case

A 52-year-old woman presented herself at the hematology clinic of Lenox Hill Hospital in August, 1951. She had been ill for a few months and had lost 42 lb. (19.1 kg.) in weight. Her normal weight was 160 lb. (72.6 kg.). She was pale, her gums were puffy and oozing, and she looked chronically ill. She had been born in Limerick, Ireland, March 3, 1898. Her mother had died of pneumonia. The patient was married and had eight children. At the age of 38 she had had a gallstone attack but no operation. Menopause occurred when she was 51. She did not smoke or drink. In February, 1951, she had been operated on for varicose veins at Lenox Hill Hospital. Her blood findings were normal at that time. Determinations done at that time were as follows: hematocrit value, 44%; hemoglobin level, 95% (14 Gm. per 100 cc.); red blood cell count, 4,600,000 per cubic millimeter; white blood cell count, 7,200 per cubic millimeter, with 68% neutrophil polymorphonuclear cells (8 nonfilamented cells), 19% lymphocytes, 9% monocytes, 3% eosinophils, and 1% basophils; and platelets, 200,000 per cubic millimeter.

On physical examination, the positive findings were a marked enlargement of the spleen and liver and a generalized lymphadenopathy. There had been no history of a previous febrile illness, and she had not been exposed to any chemicals. The blood findings in August, 1951, were as follows: hemoglobin level, 45%; red blood cell count, 2,600,000 per cubic millimeter; white blood cell count, 52,000 per cubic millimeter, with 81% lymphocytes, 18% polymorphonuclear cells, and 1% monocytes; and platelets, 90,000 per cubic millimeter. The lymphocytes were of the small type. There were no Downey cells, and the heterophil agglutination test gave negative results. The sternal bone marrow (fig. 1) showed marked infiltration by small lymphocytes and was considered typical of chronic lymphocytic leukemia. A cervical lymph node (fig. 2) was removed on Aug. 9, 1951, and the report of the pathologists, Drs. R. M. Paltauf and G. L. Rohdenburg, was as follows: "Microscopic examination reveals a lymph node the normal architecture of which is obscured. All the sinusoids are filled with large and small lymphocytes and similar cells are seen infiltrating the capsule. Diagnosis: lymphocytic (lymphatic) leukemia."

She was then treated by transfusion and x-ray. Her blood group was O, Rh-positive. She had seven hospital admissions, during which she received 22,500 cc. of whole blood. Transfusions were given on the following dates: Aug. 7, 8, 9, and 11, 1951, Feb. 26 and 27, May 2, Sept. 18, 22, and 24, and Dec. 19, 20, 21, and 22, 1952, and Feb. 10, 11, 13, 14, and 15 and April 12, 13, and 14, 1953. She was also given x-ray treatment to the anterior part of the spleen according to the following schedule: A Picker oil-cooled machine was used, with 200 kv., 15 ma., target-skin distance 50 cm., portal size 10 by 15 cm., 0.5 mm. Cu–1 mm. Al filtration, and 36 r

---

From the Medical Service, Lenox Hill Hospital.

per minute. Irradiation was given for two and three-fourths minutes (100 r) the first day of therapy and five and one-half minutes (200 r) subsequently for a total of six times and 1,100 r. The dates of therapy were Dec. 22, 24, and 29, 1952, and Jan. 2 and March 26 and 31, 1953.

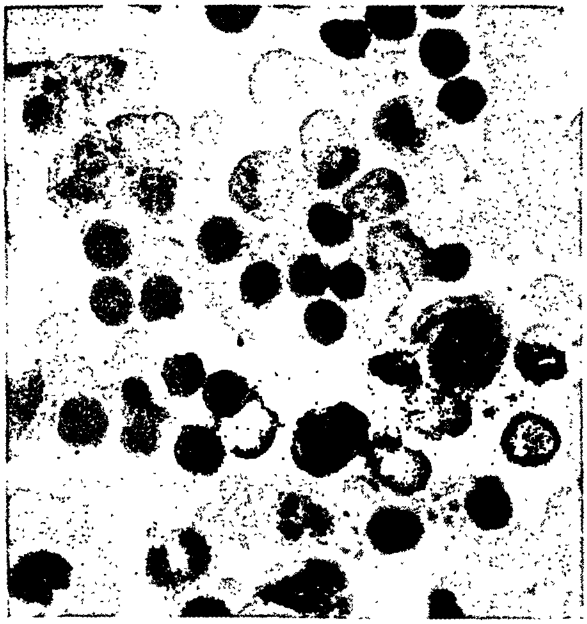

Fig. 1.—Photomicrograph of sternal bone marrow, taken in August, 1951, showing marked infiltration by small lymphocytes.

When she was not in the hospital she was treated at the clinic, where she received a total of 56 injections of liver extract. Following are some interesting notes from her chart: On Sept. 27, 1951, medical attendant Dr. T. J. Morrison noted the spleen to be hard and to extend below the iliac crest and the lymph nodes to be enlarged. On Dec. 4, 1951, Dr. H. Kessler of the tumor clinic examined the patient, found the spleen palpable below the iliac crest, and gave the diagnosis of chronic lymphocytic leukemia. On Dec. 5, medical attendant Dr. R. Gearhardt noted generalized lymphadenopathy and the spleen markedly enlarged and hard. A similar notation was made by medical attendant Dr. Robert Schleussner on Feb. 18, 1952. On April 14, 1952, pain, aching in character, in the left upper quadrant was noted by medical attendant Dr. Colter Rule. On May 3, 1952, the diagnosis of chronic lymphocytic leukemia with splenic infarct was made by Dr. Edgar Lawrence, medical director. At that time blood findings included white blood cell count 45,500 per cubic millimeter, with some blast cells and 85% lymphocytes, hemoglobin level 9 Gm. per 100 cc., and red blood cell count 3,100,000 per cubic millimeter. The diagnosis of chronic lymphocytic leukemia with splenic infarct was again given on Oct. 2, 1952, when blood findings showed the hemoglobin level to be 7 Gm. per 100 cc., white blood cell count 51,000 per cubic millimeter, with 87% lymphocytes, and blood urea nitrogen level 40 mg. per 100 cc. On July 9, 1953, physical examination, done by Dr. Alexander Vongries, chief medical resident, revealed the patient to be poorly nourished, pale, and chronically ill. Her gums were pale, soft, and spongy and bled easily. The spleen was firm and tender and extended below the iliac crest. The liver was palpable three fingerbreadths below the costal margin. The cervical, axillary, and inguinal nodes were enlarged. The diagnosis was chronic lymphocytic leukemia.

As seen by these clinical notes by various attending physicians, she made no progress from August, 1951, to July, 1953. The spleen remained just as large and just as hard, and the liver and lymph nodes also remained enlarged.

The anemia persisted except for temporary improvement after transfusions, and the white blood cell count varied from time to time, depending on the x-ray effect.

Finally, in July, 1953, she came to me and asked if she could revisit Ireland before she died. I consented, and she left by plane with her sister. On her return from Ireland in September of the same year I saw her again and hardly recognized her. She had gained 25 lb. (11.3 kg.) in weight, and her skin was ruddy. The lymph nodes were no longer enlarged, and the spleen and liver were normal in size. She told me that one evening in August, while sitting in front of the fire in her little home outside of Limerick, she put her hand on

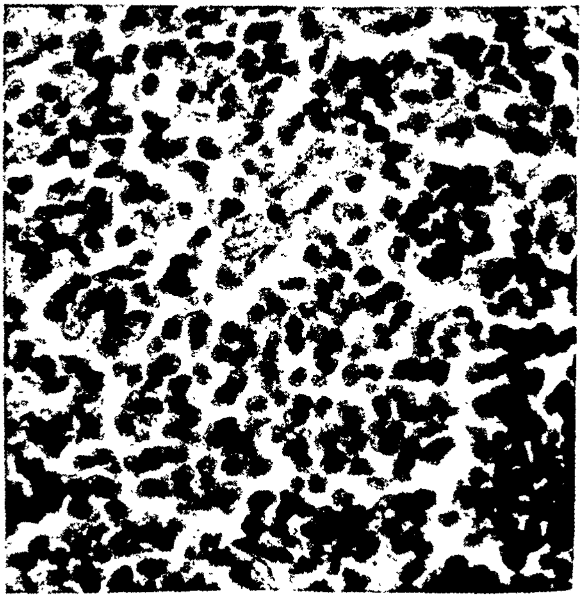

Fig. 2.—Photomicrograph of lymph node, taken in August, 1951, showing obscuring of normal architecture.

her abdomen, and, instead of the usual hard mass which had been present, the entire abdomen was now soft. Her blood cell count and bone marrow were normal on subsequent examination.

Over the succeeding years, careful, repeated blood and bone marrow tests have been done, and all have given normal results.

Typical blood findings (March, 1958) have been as follows: hematocrit value, 46%; hemoglobin level, 100% (14.5 Gm. per 100 cc.); red blood cell count, 5,000,000 per cubic millimeter; white blood cell count, 7,500 per cubic millimeter, with 67% neutrophil polymorphonuclear cells (9 nonfilamented cells), 17% lymphocytes, 12% monocytes, 3% eosinophils, and 1% basophils; and platelets, 200,000 per cubic millimeter. A photomicrograph of the sternal bone marrow, taken in March, 1958, is shown in figure 3.

On May 21, 1958, Dr. Claude E. Forkner examined the patient and reviewed the lymph node section and bone marrow smears. He was of the opionion that the bone marrow and lymph node sections taken in March, 1951, were typical of lymphocytic leukemia. He also noted that the patient showed no clinical evidence of leukemia on May 21, 1958, and that the blood and bone marrow taken March, 1958, were completely normal. His personal note is as follows:

"This patient would seem to represent an almost unique situation in which she has remained well without treatment for a period of five years. In spite of the prolonged and apparently complete remission she should be followed with care for any indication of relapse. Patients with chronic lymphocytic leukemia on rare occasions may have long asymptomatic remissions but usually such remissions are not complete so far as the blood count is concerned. The wise physician refrains from treating patients with asymptomatic chronic leukemia because of its possibility of upsetting an equilibrium in which natural forces are holding the disease in check."

On June 20, 1958, this patient was presented before the entire medical staff at Lenox Hill Hospital at a weekly conference. Dr. Edgar Lawrence was the chairman, and Dr. Claude E. Forkner led the discussion. Everyone present was satisfied with the evidence presented, and there was no dissenting discussion.

The following recent review of the pathology of the lymph node removed in August, 1951, was made by Dr. Maurice N. Richter, director, department of pathology, New York University–Bellevue Medical Center: "The section of lymph node . . . is from a case of malignant lymphoma and is quite consistent with the clinical diagnosis of lymphatic leukemia."

Comment

It is possible that this patient is in a period of prolonged remission. In leukemia, especially of the lymphocytic type, a long remission may either occur spontaneously or be produced by therapy. However, this case is distinguished by the fact that for the last five years the patient has shown no clinical or hematological evidence of the disease.

This finding leads to many interesting speculations. It is possible that some factor in the blood of one of the donors may have had a salutory effect on the outcome of her disease. Whatever the cause of her recovery, the important lesson to be learned from this case is that there is hope even in such a dreadful disease as leukemia. This should give some comfort to the many patients suffering from leukemia and to their anxious relatives.

Summary

In a case of chronic lymphocytic leukemia, complete recovery has apparently taken place and has persisted for five years. The diagnosis was substantiated by typical blood, bone marrow, and lymph node biopsy findings, as well as a two-year hospital course typical of a severe leukemia. The patient subsequently has had a five-year period of complete freedom from any physical, blood, or bone marrow abnormalities. These observations provide a note of hope on the outlook of leukemia.

COMMON OCULAR TRAUMA

Dan M. Gordon, M.D., New York

Physicians who are not ophthalmologists sometimes are obliged to treat eye injuries either because of the nature of their practice or because the situation demands immediate medical care. The minimum equipment includes some form of magnifier, a source of light, and a treatment tray, the contents of which are here listed. Chemicals splashed into the eye must be removed by immediate washing if possible, and time should not be lost searching for appropriate neutralizers. Penetrating wounds of the cornea are dangerous, especially if they have perforated the lens or iris. If a corneal injury is too deep for immediate diagnosis or treatment, the eye should be covered and immobilized until expert attention can be given in favorable surroundings. The infrared radiation from an atomic flash, even at distances exceeding 70 km. (45 miles), can cause a choroidal burn before the blink reflex can close the eye. Safety measures to forestall injury are best, but when injury has occurred rational first aid minimizes later complications.

The frequency with which a physician sees a specific type of ocular injury depends on the nature of his practice. In an industrial neighborhood foreign bodies and flash and hot oil burns would be most common. In a residential section, with a high percentage of housewives, there would be injuries due to foreign bodies, corneal abrasions caused by brushes and infants' fingernails, and contusions due to open cabinet doors. In the event of a thermonuclear attack, radiation burns would present problems entirely different from those of everyday practice. The most common ocular injuries are those due to foreign bodies; direct blows causing abrasions, contusions, and lacerations; and thermal, chemical, or radiation burns.

The presence of anything in the eye which does not belong there constitutes an emergency. The foreign material must be removed by the quickest, safest method possible, usually by irrigation with water or some other bland fluid. Educational programs for children, workers, and housewives should stress the importance of immediate and copious irrigation with water, milk, or any other bland fluid when foreign material of any type enters the eye. After this generous eye bath the patient should consult a physician. Immediate attention will often prevent blindness, especially in the case of chemical burns.

Workers who are exposed to flying objects or sources of flame should wear goggles. Hobbyists and "do-it-yourselfers" should be warned to use adequate protective devices. Incidentally, any patient who is struck in the eye with a flying particle while he is using a hammer or other metal object should be instructed to bring in the tool so that it can be determined whether it is magnetic or nonmagnetic. It will also be helpful to locate the particle, because it can then be matched against the tool from which it came to see if any missing portion may still be within the eye.

Materials and Method

This paper is directed at those who are not ophthalmologists yet who may find it necessary to treat eye injuries, either because of the nature of their practice or because the exigencies of the situation demand medical care before a specialist can be summoned. Visual loss which is not obviously of a temporary nature demands consultation and treatment by an ophthalmologist. Before the nonspecialist can treat ocular injuries he must be prepared to approach the eye. This demands a minimum amount of equipment, including (1) some form of magnification, preferably a loupe, consisting of a combination of convex lenses and prisms, which can be worn either as an eyeglass or in a head band; (2) a source of focal light, preferably a floor lamp, which throws a bright, narrow beam; (3) a treatment tray which should contain cotton balls; toothpick swabs; sterile fluid for irrigation, preferably in a squeeze bottle or an atomizer; topical anesthetic (0.5% tetracaine solution, proparacaine hydrochloride [Ophthaine], or benoxinate [Dorsacaine] hydrochloride, not cocaine); a spud for removing foreign bodies or hypodermic needles which can be used for the same purpose; fluorescein for staining the cornea; a lid retractor; a cycloplegic drug (0.5% homatropine solution or 0.5% cyclopentolate hydrochloride solution); eye pads; and scotch tape.

Although fluorescein solution comes in bottles of 1.0% concentration it is preferable to use fluorescein strips which come in individual, sterile packages. Since fluorescein is an excellent culture medium for Pseudomonas aeruginosa (pyocyanea), the individual strips eliminate the dangers of contamination inherent in using bottles of the solution. Actually, the less one relies on stock bottles and eye droppers the less is the danger of contamination. If a lid retractor is not available a heavy bent hairpin may serve the purpose. While cycloplegic drugs should

Read in part before the 12th Clinical Meeting of the American Medical Association, Minneapolis, Dec. 3, 1958.

be available they should rarely be used by the general practitioner and never after the removal of a simple foreign body. Many patients have been practically immobilized for a week or two by a dilated pupil, caused by the unnecessary instillation of atropine, after a trivial injury.

It is mandatory to obtain a history of the accident, preferably from the patient himself, at the first visit, before "compensationitis" has had a chance to set in. It is amazing how often a simple foreign body in one eye will cause a need for reading glasses in a person over 40 years of age. He has consciously or unconsciously neglected to do anything about his presbyopia before the accident and now becomes convinced that it was caused by the foreign body. Also, long after the accident has occurred the patient is frequently persuaded that the "rich" insurance companies are in a better position to take care of him than he is. If possible, vision with and without glasses should be determined and recorded before the eye is treated. Prognosis should not be discussed until the outcome is certain.

Every physician should learn how to evert the upper lid. It is important to have complete control of the patient. If the upper or lower lid is held firmly against the superior or inferior bony margin of the orbit, the patient will be unable to close his eyes when he squeezes. A head rest makes immobilization easier.

Whenever the cornea is involved it should be stained with fluorescein so that any denuded areas may be more effectively highlighted. A drop of fluorescein is instilled into the anesthetized eye. After a minute the eye is irrigated with sterile saline solution or water. It is advisable to place a plastic apron of the type used in beauty parlors around the patient's neck as people resent having their clothes saturated with irrigating solution, especially if it is tinged with fluorescein. In addition to the major advantage listed above, the use of fluorescein strips will diminish this possibility. The patient should be asked to look up and the fluorescein strip can be placed inside the lower lid of the anesthetized eye, which should then be closed for a few moments. Irrigation is unnecessary. The eye may then be examined with good focal illumination and magnification.

Some important points to remember in examining an eye, in addition to those that have been mentioned above, are as follows: 1. Always evert the upper lid, since foreign bodies commonly tend to lodge on the shelf just inside the upper lid border. 2. If a foreign body cannot be found, hold the everted upper lid up while the patient looks down, and explore behind the lid with a moistened, tightly wound cotton toothpick swab to ascertain if any foreign material is lodged in that blind area of the cul-de-sac. 3. Irregularity of the light reflexes on the cornea or loss of the normal mirror-like relucency of the cornea indicates corneal injury or edema. 4. Blood in the anterior chamber, dilation or paralysis of the pupil not due to medication, distortion of the pupil, or subconjunctival hemorrhage after a history of a blow to the eye indicates possible ocular damage. A shallow anterior chamber in comparison with the other eye points to a probable penetrating injury. 5. Normal vision is compatible with serious eye injuries. 6. Always examine with an ophthalmoscope, employing a highly convex lens (+12 or +15) and starting 6 or 8 in. from the patient's eye. Focus on the pupil and the red reflex, and slowly decrease the degree of convexity as you approach the pupil and examine the fundus. A corneal scar, foreign body, or lens opacity is seen as a dark spot in the red reflex. If there is vitreous hemorrhage or a large retinal detachment the normal round, red reflex will be obscured or absent. A large vitreous hemorrhage will cause a black reflex. If fundus examination reveals any abnormality, consultation with an ophthalmologist should be secured. A retinal detachment is usually seen as a gray elevated area over which the retinal vessels are black rather than red. 7. An iris which trembles during movement of the eye indicates that the lens is either dislocated or absent. 8. A "black eye" or bleeding from the nose or ears following a head injury may indicate cranial damage.

Injuries to the Orbit

Injuries to the orbits may involve soft tissue trauma with bleeding, lacerations of the brow, or fractures of the orbital rim. An important injury is the "Herb Score" type, in which the patient is struck in the region of the orbit with a baseball or softball. This is commonly seen in adults who play rarely and who have not learned that men should not play boys' games. The orbital rim will usually cushion a blow against the eye unless the offending object hits the relatively unprotected temporal side. A softball, with its larger circumference, is more apt to cause bony injury than is a baseball.

Emphysema and crepitation on palpation suggest fracture of the orbital rim and demand x-ray examination. When a fracture of the floor of the orbit is not promptly corrected the eyeball will drop and severe diplopia will result. Simple lacerations of the orbital skin are sutured in routine fashion. Sudden loss of vision accompanying an injury to the globe may mean fracture of the orbit resulting in laceration of the optic nerve or hemorrhage into the nerve sheath.

Blows to the lids most commonly cause ecchymosis, the common black-and-blue eye. This rapidly responds to daily intramuscular injections of 1 cc. of chymotrypsin. The injection of 20 units of hyaluronidase into the discolored area will stimulate more rapid absorption of the blood. This is inadvisable in aged and debilitated patients, however, as it may produce more bleeding.

Simple lacerations of the skin may be closed with 00000 or 000000 silk sutures. If the laceration is through the lash margin of the lid, one must approximate the cut distal edges or else lid notching will occur. When the laceration is deep the lid must be closed in layers. If the laceration extends through the conjunctiva, the cut ends of the sutures should be buried within the lid or they will abrade the cornea. If the laceration is between the punctum and the nose one should ascertain whether the lacrimal canaliculus is severed, as this calls for specialized care. If an ophthalmologist is not available, the physician should attempt to push a fine wire, polyethylene tubing, or stiff catgut suture through the punctum and then out the cut end of the canaliculus and into its other cut end as far as possible. Because of its delicacy, loss of any appreciable amount of lid skin demands plastic surgery to prevent lid distortion with eversion of the lash margins and consequent lacrimating and discomfort, or inversion of the lash margins with resultant denuding and scarring of the cornea. Partially severed ocular tissues which hang down, as, for example, the edge of an eyelid with its lashes, and are almost completely separated from the rest of the lid will often heal with amazing rapidity. Extensive débridement or excision of such dangling tissue areas should not be done unless absolutely indicated.

Injuries to the Conjunctiva and Cornea

Small lacerations of the conjunctiva need not be sutured. Any laceration of the conjunctiva means that a penetrating injury must be ruled out. Chemicals which enter the conjunctival sac must be removed immediately by copious irrigation. Solid chemical particles which remain, especially lime and plaster, must be removed with fine forceps. The area of the upper cul-de-sac should be thoroughly irrigated. Corneal and conjunctival injuries present similar problems when chemicals are involved. Acid burns tend to cause immediate, usually localized, nonprogressive tissue necrosis. Alkali burns, such as those due to plaster and lime, are dangerous and progressive, especially if any residual particles are not removed. At this point it must be emphasized that neutralization of chemicals is passé. One no longer waits to neutralize a chemical, but washes it out as rapidly as possible. The patient's eye should be irrigated promptly at the work site with water from a pan, bucket, hose, or any other handy source of supply, or his head should be held in a bucket of water or under a running tap with the lids forcibly held open.

Corneal burns heal more rapidly when treated with topically administered steroids. Chemical gases may penetrate the cornea and enter the globe, necessitating paracentesis of the anterior chamber. This procedure demands the attention of an ophthalmologist. The danger of this type of injury should be borne in mind.

When chemicals enter the cul-de-sac they may create adhesions between the abraded conjunctiva and the cornea. These should be prevented by (1) instilling bland ointments between the lids, (2) avoiding complete immobilization of the eye for long periods, and (3) inserting a shape-retaining conformer made of dental wax or some similar material into the cul-de-sac if the burn is severe. Occasionally, contaminated foreign material in the cul-de-sac will result in an internal (meibomianitis) or external hordeolum (sty) after several days.

The physician's aims are to control pain, remove foreign substances, stimulate healing, or at least not interfere with it, prevent anatomic distortions, and produce maximal visual recovery. To that end, topical anesthesia may be used when the patient is first seen, but as infrequently as possible thereafter. Where intense lid spasm is present the anesthetic will enable the patient to open his own eyes and cooperate with the physician, but topical anesthetics tend to delay healing and should therefore be used sparingly. Antibiotic ointments also tend to interfere with healing and should be used only if infection is present or feared. One should never put any medicament into the eye just for the sake of doing something. Topically administered steroids are not indicated after the removal of simple corneal foreign bodies and may be deleterious in the event that herpes simplex virus is present. Steroids minimize reactions in keratitis after reactions to incomplete rust ring removal. Contamination in the physician's office may result in infection of the wound and possible loss of the eye. Sterile solutions and instruments should be used; this means that one should not have his solutions made up by the druggist but should buy already prepared sterile products.

Metallic foreign bodies are usually associated with rust rings. The foreign body can be lifted out with the tip of a sterile cataract knife, a corneal spud, or a hypodermic needle with use of focal illumination and magnification. If the foreign body is deep in the cornea it should be removed by an ophthalmologist. An iris freckle must not be mistaken for a corneal foreign body. The eye should be patched after a corneal foreign body has been removed.

Removal of rust rings is difficult and usually requires the use of a slit lamp. At times one can touch the area of the rust ring gently with 1% silver nitrate solution on the tip of a tightly wrapped applicator. The eye should then be patched for 24 hours. The next day the whole area can usually be lifted out with the sharply pointed end of a narrow knife or a needle. It is not advisable, however, for a nonophthalmologist to apply silver nitrate solution to the cornea, and this procedure should be attempted only in emergency situations.

Occasionally a large number of foreign bodies will be seen in a cornea. When it is evident that attempted removal of these foreign bodies, especially in the pupillary area, might result in considerable corneal scarring and consequent loss of vision, it may be wise to wait and allow the foreign bodies to extrude themselves. I have seen two cases in which the corneas were spattered with hundreds of foreign bodies as a result of backfire during target practice. In both cases, the foreign bodies extruded spontaneously over a period of months. Attempts at removal would have resulted in considerable visual loss because of corneal scarring caused by the instrumentation. This advice does not apply, however, when metallic foreign bodies are present; these should always be removed as promptly as possible.

If a protruding foreign body has penetrated through the cornea into the anterior chamber it is best not to attempt removal but to refer the case immediately to an ophthalmologist. Attempts to remove these protruding foreign bodies frequently result in breaking them off, rendering later removal difficult.

Corneal abrasions rarely require more than a cleansing irrigation and a tight pressure patch for from 24 to 48 hours. A double eye pad should be affixed with multiple strips of firmly placed adhesive tape to produce the desired pressure and immobilization of the abraded globe.

When the attending physician cannot handle a corneal injury or estimate its gravity, the eye should be patched and thus immobilized until more expert attention can be secured. If the injury is a penetrating one both eyes should be patched. Corneal lacerations may require suturing. Blows or lacerating injuries to the cornea demand ophthalmoscopic examination to rule out hemorrhage, retinal edema, or detachment. Blows to the eye may produce ruptures of the choroid which are seen as semilunar white rings, concentric and usually temporal to the optic nerve. Traumatic anterior chamber hemorrhages tend to be recurrent and may produce secondary glaucoma.

Penetrating wounds of the cornea are always potentially dangerous, especially if they have perforated the lens or iris. One should note the depth of the anterior chamber by comparing it to the other eye. If a pupil is irregular or protrudes through the laceration an ophthalmologist should be consulted immediately. One should avoid the error of trying to wipe a blood clot away from a wound only to discover that it is a prolapsed iris. If the services of an ophthalmologist are not available when the iris is prolapsed the prolapsed portion should be excised with sterile scissors, after which a cycloplegic such as atropine should be instilled. Deep injuries of the cornea and iris are accompanied by iritis.

Burns

Flash burns and ultraviolet radiation burns of the cornea rarely cause any serious problem except for the initial discomfort and lid spasm, which may last for several days. Burns due to boiling water, flames, or hot grease which have not caused serious corneal damage also belong in this category. A drop of topical anesthetic should be immediately instilled into the eye of the victim to show him that he can open his lids and that he has not been blinded. Such burns are best treated with cold compresses, phenacaine (Holocaine) hydrochloride, epinephrine ointment several times a day for the first few days, a decongestant (tetrahydrozoline [Visine] hydrochloride, naphazoline [Privine] hydrochloride, or phenylephrine hydrochloride, ⅛% solution) two or three times a day, and ample reassurance. Lid burns should be treated in the same manner as skin burns elsewhere.

In these days of potential atomic warfare it is advisable for the physician to know something about ocular injuries during atomic attack. Byrnes and co-workers [1] have shown that it is possible for the eye of a person facing in the direction of the exploding weapon to suffer injury as far as 45 miles away from the blast. While the eye represents a relatively small portion of the total body area, its injury rate may be out of all proportion to its size. External eye burns due to atomic radiation are much like burns from other causes, the one difference being that because the blink reflex is much slower than the speed of the light delivered by the atomic flash the inside of the eyeballs may be burned before the blink reflex can close the lids. The atomic energy which is delivered to the inner eye through the open pupil results in a choroidal burn which is permanently damaging and for which little can be done. At the time of the burn there is considerable edema of the surrounding retina and choroid. It is probable that the immediate systemic administration of a large dose of ACTH or one of the steroids would prevent much of the damage due to the edema itself. The size of the pupil controls the amount of damage suffered by the inner eye. All other things being equal, including the distance from the exploding atomic weapon, less light intensity is delivered to the inside of the globe if the damage takes place in daylight when the pupil is normally narrower. If the explosion occurs at night when the pupil is normally dilated the damage is likely to be much more severe. The moral, then, is to avoid being anywhere near an exploding atomic weapon. If you are, and you cannot get to a safe place, arrange to be exposed in daylight, face in a direction opposite that from which the blast comes, and keep your eyes closed. One is apt to be lulled into false security by being many miles away from the explosion. As Byrnes has shown, this security becomes less with each increase in potency of atomic weapons.

Summary

The nonophthalmologist is commonly apt to encounter various ocular traumas and should know something of their management. In the main, this is one field where prevention through safety measures and prompt attention to rational first aid is often worth more than later attempts at cure.

RISTOCETIN—A STATISTICAL REVIEW OF THREE HUNDRED THIRTY-THREE CASES

Robert L. Herting, M.D., Brian Lees, M.R.C.P., Albert J. Zimmermann, B.A.
and
George H. Berryman, M.D., North Chicago, Ill.

Reports received by a manufacturer from physicians using ristocetin, a new antibiotic, were collated with reports published in clinical literature, and the results were analyzed. Among the total of 333 cases in which the drug was used, there were 126 cases of pneumonia, and approximately 70% of these were caused by staphylococci. There were 46 cases of subacute bacterial endocarditis, and approximately 50% of these were caused by staphylococci. The drug was given either by intravenous injection or prolonged intravenous infusion. The most frequent side-effects were thrombophlebitis (20 cases, 6% of the total) and neutropenia (18 cases, 5.4%). Side-effects were absent in 258 (77.5%) of the patients. The side-effects were most frequent in patients receiving the larger doses, and on the basis of these findings it is recommended that the dosage of this antibiotic in adult patients should not normally exceed 2 Gm. per day. Approximately 60% of the patients were completely cured.

When a new therapeutic agent is introduced, a pendulum is set swinging. Often, first reports are enthusiastic. Later, limitations in the use of the drug may become more apparent. Adverse reports may be the result of disappointment when the drug fails to serve as a universal panacea. Finally, the pendulum comes to rest as indications and limitations are generally recognized.

When a new antibiotic becomes available and when the use of this antibiotic is generally restricted to serious cases, it is difficult for any person to amass a large series of cases within a short time. Experience will vary, and conflicting reports may make it difficult to determine the over-all usefulness of the new agent.

In this situation, physicians working within the medical department of the manufacturing pharmaceutical house occupy a unique position. They have access to detailed clinical reports from many physicians, and if results from a comparatively large number of cases can be correlated and presented without bias this information should be of considerable value to the profession as a whole.

It has been our objective to review all clinical reports on ristocetin (Spontin) during the first year of its use. This survey embraces 333 cases and includes those published in the literature,[1] as well as reports submitted directly by clinicians to us. To minimize personal factors in the evaluation of these reports, analysis has been conducted entirely by machine methods.

Methods and Results of Study

Information from each of the 333 case reports was translated into a numerical code suitable for punching into a standard IBM card. No attempt was made to "edit" the information supplied by the reporting physician. The tables were compiled by sorting these punched cards into the categories indicated.

It can be appreciated that not all the case reports were as complete as we might have wished. The main departure from an "ideal" report was in the area of bacteriology. It can be seen from table 1 that in about 20% of the cases the causative organism was not designated. In many of the cases, too, sensitivity of the organism to various antibiotics was not recorded. Nevertheless, the figures indicate that staphylococcic infections were treated much more frequently than others.

Also in table 1, it can be seen that in approximately one-third of the patients treated with ristocetin the diagnosis of pneumonia was given. In this group of 126 patients, approximately 70% of the infections were staphylococcic. The next largest group, with subacute bacterial endocarditis, included 46 patients, with approximately 50% of the infections identified as staphylococcic and a further 15% as enterococcic.

A point of major interest with regard to a new therapeutic agent is the incidence and type of side-reactions which occur (table 2). Some interesting points emerge from this analysis. Almost 80% of the patients have shown no side-effects. In some instances, it has not been possible to determine whether a toxic effect should be attributed to the disease process, to the administration of another therapeutic agent, or to the administration of ristocetin. Such cases have included proteinuria (two), gastrointestinal upset (one), impairment of hearing (two), and acute anemia (one). The rarity of these occurrences and the fact that in every in-

nediastinal abscesses and empyema. This was
eflected in the high mortality.

ypoproteinemia and Gastric Carcinoma.—A study f 67 patients with gastric carcinoma was underaken by H. Sunzel (*Acta chir. scandinav.* 116:429-36, 1958/1959) in order to clarify the nature of the reoperative hypoproteinemia associated with that ondition. Hypoproteinemia does not appear to be pecific to cancer but may result from nutritional eficiency and pathological loss of protein. In paients with a history suggestive of protein depletion he operative mortality was found to be five times s high as in those without any such history of proein disorder. The excessive mortality was due to oor healing of the anastomosis and increased suseptibility to infection. Malignant neoplastic disase is often characterized by a decreased concen-

were about equally represented in undergoing partial or total gastrectomy for carcinoma of the stomach, and preoperative hypoproteinemia was observed in 34 instances. Inadequate intake owing to mechanical obstruction and excessive loss of protein due to hemorrhage appeared to be responsible for the hypoproteinemia. Patients with a history of protein depletion—not always reflected in the serum protein level because of coexistent dehydration—had an operative death rate of 31% as opposed to a rate of 6% in those in whom no similar history was recorded. It does not suffice to administer only protein or amino acids in the hope of restoring optimal protein synthesis. The administration of protein without accompanying calories to an emaciated patient results only in the utilization of the protein chiefly for energy requirements. Modern principles of treatment with a high-calorie diet plus protein may be capable of partially or wholly restoring the protein deficit in cancer patients before time leads to deterioration of the patient's condition due to the basic malignant disease.

UNITED KINGDOM

Stricter Test for Disability Urged.—A sterner line in assessing disability was suggested by Dr. H. C. J. L'Etang in the *Practitioner.* He cited the case of many men whose deafness, poor sight, disabled limbs, and diseases did not prevent their reaching the top in sports and asked whether the conscientious physician could definitely state that loss, or malfunction, of a limb, or special sense organ, invariably led to disability.

Echoencephalography.—An apparatus employing ultrasonic waves for diagnostic purposes was designed by Gordon (*Brit. M. J.* 1:1500, 1959). It is a modification of that used for detecting and locating submarines (asdic) and for detecting flaws in large masses of metal. The physical principle underlying the use of ultrasonic waves is the piezoelectric effect, that is the result of an electric charge on opposing surfaces of a crystal when under stress. At the frequencies employed in medicine the ultrasonic rays are produced by crystals of quartz or barium titanate. The rays are closer in type to sound waves than to radio or x-rays. They are backward and forward movements of the molecules of the transmitting medium.

stance there was an alternative explanation suggest that ristocetin was possibly not the responsible agent.

Also of interest is the clear relationship of side-effects to dosage. This is demonstrated in table 3. The recommended dosage of this antibiotic for most infections is 2 Gm. per day (for the adult patient). At this dosage level, side-effects have not been troublesome. However, it is clear that when this dosage is exceeded (and particularly when a dosage in excess of 3 Gm. a day is given), the incidence of side-effects rises steeply. It should also be recorded that a similar relationship can be demonstrated between the total dosage of ristocetin administered and the incidence of side-effects. It is known that ristocetin is excreted by the kidneys and that at high dosage (or when renal function is impaired) the antibiotic may accumulate in the blood and tissues. This laboratory finding probably accounts for the relationship between dosage and side-effects.

Table 1.—*Analysis of 333 Cases by Bacteriological and Pathological Diagnosis*

Organism	No. of Cases	%
Staphylococcus	211	63.4
Streptococcus	12	3.6
Pneumococcus	10	3.0
Enterococcus	11	3.3
Mixed organisms	16	4.8
Organism undesignated	73	21.9
Diagnosis		
Pneumonia	126	37.8
Subacute bacterial endocarditis	46	13.8
Septicemia	38	11.4
Abscesses	32	9.6
Osteomyelitis	24	7.2
Cellulitis	10	3.0
Enterocolitis	8	2.4
Wound, surgical infection	6	1.8
Furunculosis	7	2.1
Meningitis	3	0.9
Bronchitis	3	0.9
Cystitis	3	0.9
Peritonitis	3	0.9
All others	24	7.2

Table 2.—*Relative Incidence of Side-effects in 333 Cases*

	No. of Cases	%
None	258	77.5
Neutropenia	18	5.4
Drug fever	12	3.6
Skin rash	14	4.2
Depression of platelet count	5	1.5
Thrombophlebitis	20	6.0
All others	6	1.8

It should also be recorded that the over-all incidence of side-effects has declined during the later months of this first year of ristocetin usage. There are three possible explanations for this observation: 1. An improvement in the manufacturing process about six months ago eliminated certain impurities from ristocetin; the antibiotic is now prepared from pure crystalline material. 2. There has been a tendency to eliminate unnecessarily high dosage. 3. A number of clinicians have used intravenous injection (over a period of 5 to 15 minutes) rather than prolonged intravenous infusion. This technique has materially reduced the incidence of thrombophlebitis. It is a logical assumption that the second explanation should also contribute to a reduction in side-effects, and it is possible (though difficult to prove at this time) that the first explanation may be an additional factor.

Finally, it can be stated that these reports indicate that all side-effects from ristocetin are reversible. The most disturbing side-effect has been neutropenia, but this (together with other side-effects) has responded promptly to either discontinuance of medication or, in some instances, reduction in the dose of antibiotic.

Table 3.—*Incidence of Side-effects Related to Daily Dose*

Maximum Daily Dose, Gm.	Side-effects, %
0.1-0.9	3.1
1.0-1.9	9.4
2.0-2.9	21.2
3.0-3.9	37.8
4.0-4.9	41.0

An examination of the over-all results (table 4) shows that approximately 60% of the patients treated were completely cured. A further 17% were classed as "improved." This category usually included patients in whom the infection responded to antibiotic therapy but in whom a full return to health was prevented by other pathological conditions.

There remains 23% of cases in which "no response" was reported. A detailed examination of this group showed a high incidence of moribund or virtually "hopeless" cases. Often there was some complicating factor unamenable to antibiotic therapy. For example, in the pneumonia group, the illness might be the terminal event in a case of lung cancer. In the bacterial endocarditis group, cardiac function might be so impaired mechanically as to make recovery unlikely. An appreciable number of patients in whom "no response" was recorded received only a few doses of the antibiotic before death intervened.

Table 4.—*Analysis of Response to Treatment*

Organism	Cured, No.	Improved, No.	No Response, No.	Total
Staphylococcus	118	44	49	211
Streptococcus	5	1	6	12
Enterococcus	10	0	1	11
Pneumococcus	8	1	1	10
Mixed organisms	14	0	2	16
Organism undesignated	46	11	16	73
Total	201	57	75	333

Summary and Conclusions

In a review of detailed case reports on 333 patients treated with ristocetin (Spontin), statistical analysis by machine methods led to these conclusions: The major use for ristocetin has been the treatment of staphylococcic infections. Side-effects are seldom troublesome, if a daily dose of 2 Gm. is not exceeded. Side-effects rise steeply when dosage is increased. The most disturbing side-effect after the administration of ristocetin has been neutropenia. However, in all instances this has responded to either discontinuance of medication or reduction in dose. The administration of ristocetin has brought about a cure in 60% of the cases reviewed and improvement in a further 17%.

NEW OPHTHALMIC DECONGESTANT, TETRAHYDROZOLINE HYDROCHLORIDE

CLINICAL USE IN 1,156 PATIENTS WITH CONJUNCTIVAL IRRITATION

Harold C. Menger, M.D., Brooklyn, N. Y.

Tetrahydrozoline hydrochloride is a sympathomimetic agent which causes local vasoconstriction when topically applied and a rise of blood pressure when given systemically. Instilled as a 0.05% solution into the eye, it was found to afford prompt relief, lasting from one to four hours; from the congestion accompanying allergic or chronic conjunctivitis. It was administered in doses of a single drop instilled into each eye two to four times daily in 1,156 patients with these conditions. This dose, while sufficient to give the desired relief in the majority of patients, had no side-effects beyond a mild, transient irritation. It did not raise the intraocular pressure and had no adverse effects when used for periods up to two years in patients with cataracts. There was no evidence that it affected the course of cataract or hindered recovery from chronic conjunctivitis or from the subacute stage of acute conjunctivitis.

Today, more than ever, the ophthalmologist is appreciative of the benefits accruing to patients from the use of nonspecific preparations in the management of conjunctivitis. Ideally, such adjunctive local preparations should have the following features: (1) optimum activity at low concentration; (2) few or no side-effects; (3) prolonged stability; and (4) no masking or increased likelihood of secondary infection.

Preliminary observations on tetrahydrozoline (Visine) hydrochloride, a unique pressor amine, indicate that it has optimum activity at a low concentration (0.05%). It has been reported that this agent is an effective and well-tolerated ophthalmic decongestant.[1] Because of the apparent utility of this decongestant, it was decided to thoroughly evaluate tetrahydrozoline in the short-term and long-term management of more than 1,000 patients with conjunctivitis of varying etiology.

Materials and Methods

A total of 1,156 patients with allergic or chronic conjunctivitis were treated with tetrahydrozoline eye drops (0.05%). Seventy-one children, aged 3-12 years, and 1,085 teen-agers and adults, aged 12-91 years, were included in this group. The dosage schedule was one drop instilled in each eye two to four times daily. As a rule, patients were maintained on therapy with this drug for periods ranging from two weeks to two months. To determine the effect on intraocular tension, over 100 patients with cataract received tetrahydrozoline daily for a period exceeding two years. Intraocular tension was determined periodically by means of the Schiötz tonometer.

Three hundred forty-eight patients with allergic conjunctivitis were included in this study. Of this number, 271 patients concurrently received antihistamines orally to help control other symptoms.

In this program there were 808 patients regarded as having chronic conjunctivitis. These cases were roughly classified as nonspecific conjunctivitis with chronic hyperemia, chronic conjunctivitis with cataract development (in various stages), or subsiding acute conjunctivitis. In the latter category, patients received decongestant medication after the local administration of antimicrobial agents or corticosteroids, as indicated.

Results

Allergic Conjunctivitis.—Tetrahydrozoline was found to be an effective decongestant in many cases of allergic conjunctivitis. The therapeutic efficiency was somewhat enhanced, as might be expected, by the simultaneous oral administration of antihistamine agents. Without antihistaminic therapy, the administration of tetrahydrozoline produced a good effect in 43 of 77 patients, gave a fair effect in 29 patients, and was ineffective in 5 patients. When administered with antihistamines, tetrahydrozoline effected a good result in 190 (70%) of 271 patients, a fair result in 74 patients (27%), and poor or no result in 7 patients. Of the 348 patients with allergic conjunctivitis, treatment with tetrahydrozoline produced a good result in 233 patients (67%) and a fair result in 103 (30%). Only 12 patients (3%) failed to report some beneficial response.

Chronic Conjunctivitis.—Tetrahydrozoline proved to be similarly useful in the management of chronic conjunctivitis. Good responses were seen in 73 (64%) of 116 patients with acute conjunctivitis in the subacute stage; a fair effect was noted in 38 patients (32%) with this indication; and 5 did not respond. Patients with nonspecific conjunctivitis with hyperemia responded almost equally well to therapy. Of 381 patients, 218 (57%) exhibited a good symptomatic response to treatment, 126 (33%) showed a fair effect, and 37 (10%) had no significant improvement. In 311 patients in whom a chronic mild secondary conjunctivitis or follicular conjunctivitis accompanied cataract development, a good response was observed in 158 (51%) and a fair effect in 104 (33%). Of the entire group of 808 patients with chronic conjunctivitis, treatment with tetrahydrozoline resulted in a good effect in 449 (56%) and a fair effect in 268 (33%). The onset of action was generally reported to occur immediately. The duration of response after each application varied from one to four hours.

Side-effects.—In no instance did intraocular tension increase. As previously mentioned, more than 100 patients receiving tetrahydrozoline for periods as long as two years were given periodic tonometric follow-up studies; in no case did pressure increase. None of the ophthalmic reflexes appeared to be impaired by the prolonged use of the drug. There was no apparent change in pupillary size. Twenty-five patients (2.1%) reported a mild stinging sensation with instillation; however, this effect dissipated rapidly. In no instances were rebound phenomena observed. In two cases, a mild subconjunctival hemorrhage occurred; however, it appeared that this effect may have resulted from trauma due to rubbing the eyes. Where cataracts existed there did not appear to be any detectable effect of tetrahydrozoline in retarding or accelerating the pathology. The incidence of secondary infection in this series was not materially different from that expected in any random series of patients; hence, the tetrahydrozoline was not thought to reduce local tissue resistance.

Summary

Treatment with tetrahydrozoline (Visine) hydrochloride ophthalmic drops provided effective decongestant action in 96% of the patients with allergic conjunctivitis and 89% of patients with various forms of chronic conjunctivitis. More than 100 patients with cataracts were treated with tetrahydrozoline over a period of two years; in no instance did intraocular pressure increase or any significant change occur in the development of the cataracts.

In addition to its excellent decongestant action, which provided prompt symptomatic relief, an important feature of tetrahydrozoline is its low incidence of side-effects. Side-effects were limited to a mild stinging sensation in 2.1% of the patients.

202 Weirfield St. (21).

The tetrahydrozoline hydrochloride used in this study was supplied as Visine hydrochloride by the Clinical Research Department, Research Division, Chas. Pfizer & Co., Inc., Brooklyn, N. Y.

REPORT OF A SEROLOGICALLY PROVED CASE OF Q FEVER IN UTAH

Paul D. Hoeprich, M.D., John R. Ward, M.D.
and
Alexander M. Schmidt, M.D., Salt Lake City

Serologic evidence indicates that Q fever is widespread in Utah, but only one proved case has been reported previously. The second proved case occurred in a young man who worked with sheep hides. His illness started with severe malaise; subsequent symptoms were fever, headache, vomiting, profuse sweats, and cough. Radiographic examination of the chest showed a homogeneous pneumonia in the left upper lobe. Dramatic improvement began after chloramphenicol therapy was started. Q fever is caused by Ricksettsia burneti, primarily a parasite of the tick. Human-to-human transmission does not occur. The usual route of human infection is by inhalation of infected dust particles. Q fever presents as an undifferentiated pneumonia. It is specifically treatable with either chloramphenicol or any of the tetracyclines. Most of the Q fever in Utah is probably reported as influenza. Diagnosis is retrospective and is accomplished by demonstrating a rise in serum complement-fixing antibodies specific for Rickettsia burneti.

Q fever has been reported from most of the temperate and tropical areas of the world, including many states in the United States.[1] Excellent reviews dealing with this specific infectious disease are available.[2] Recently, Blank and associates [3] reported the county by county incidence of complement-fixing antibody to Q fever in residents of Utah. Serums from specimens submitted for serologic testing for syphilis, and from the American Red Cross donor service, enabled a sampling that ranged from 0.1% (Rich County) to 3.0% (Kane County) of the population of each county. Q fever antibodies were found either not at all (Daggett, Emery, Grand, Morgan, Piute, and Rich counties) or in as many as 7.7% of the serums examined (Sevier County). The authors remarked on the paradox of serologic evidence of Q fever in the absence of reports of clinical disease. This report of a case confirms the clinical presence of Q fever in Utah.

Report of a Case

A 20-year-old married male was admitted to the Salt Lake County General Hospital on Sept. 7, 1958, because of malaise and fever. Seven days before his entry, there was sudden onset of malaise sufficiently severe to cause the patient to stay home from his work as a handler of sheep pelts. Fever was noted four days before admission; dull suboccipital and bitemporal headache began the same day. Repeated vomiting, profuse sweats, and the onset of nonproductive cough three days prior to admission caused the patient to consult his physician. Penicillin was injected and tablets were prescribed, but no relief resulted. On the day of hospitalization, for the first time, a small amount of sputum was produced. There was no pleurisy, no sore throat, and no dyspnea or orthopnea.

Aside from influenza in the fall of 1957, the patient could recall no illnesses. The remainder of the patient's history and a review of systems was noncontributory. Neither the patient nor the members of his family had traveled outside of Utah within the six months before admission.

At entry, the patient's pulse was 80 beats per minute and regular, respirations were unhampered and regular at 16 per minute, blood pressure was 110/64 mm. Hg, and oral temperature was 104.2 F (40 C). There was obvious sweating; the skin was hot and moist and the face was flushed in appearance. There was no respiratory distress. The neck was supple and the trachea lay in midline. The respiratory movements of the chest were symmetrical. Vocal fremitus was increased over the upper anterior part of the left side of the chest, and there was decreased intensity of breath sounds with scattered, rather musical, inspiratory rales over the left side of the chest posteriorly. No abnormalities were found in the remainder of the physical examination.

The hematocrit was 44% and the icterus index 5. There were 11,400 white blood cells per cubic millimeter of blood, of which 32% were juvenile and 58% mature polymorphonuclear leukocytes, 9% lymphocytes, and 1% monocytes. Erythrocytes were normal in appearance, and platelets appeared adequate in numbers. A clean, midstream, specimen of voided urine had a specific gravity of 1.020, pH 5.0, no reducing substance or protein, and only a rare white blood cell per high-power field in sediment obtained by centrifugation. A stool specimen was negative for occult blood (guaiac).

From the Department of Internal Medicine, University of Utah College of Medicine and the Salt Lake County General Hospital.

The blood urea nitrogen level was 15 mg. per 100 ml.; fasting blood sugar level, 98 mg. per 100 ml.; and total protein value, 6 Gm. per 100 ml., with 4 Gm. of albumin per 100 ml. Four blood cultures and one urine culture were sterile. Throat and sputum cultures disclosed no pathogens. The Venereal Disease Research Laboratory test was nonreactive; there were no cold agglutinins in the serum. Skin tests with purified protein derivative (first and second strength), blastomycin, coccidioidin, and histoplasmin were all negative.

Radiographic examination of the chest on the day of admission showed a homogenous, segmental pneumonia in the left upper lobe. Subsequent films on the fifth and ninth hospital days showed resolution (fig. 1).

The hospital course (fig. 2) was one of little change until about 12 hours after chloramphenicol therapy was started on the fourth hospital day. Dramatic improvement began at this time, and thereafter recovery was uneventful. The patient was discharged home on Sept. 25, 1958. The results of complement-fixation tests were diagnostic of Q fever (see table). Serums were obtained from the patient's co-workers (15 specimens) and his immediate family (4 specimens); all were negative for Q fever antibodies by the complement-fixation test.

Comment

Q fever was first reported in Utah in 1956.[3] There have been no subsequent proved cases according to the records of both the Utah State Department of Health Laboratories and the Rock Mountain Laboratory of the U. S. Public Health Service in Hamilton, Mont.[4] In the survey of Blank and others,[3] 1.7% (statewide average) of Utah serums contained complement-fixing antibody to Q fever. Yet, in areas acknowledged to be endemic for Q fever, the incidence of positive Q fever complement-fixation reactions may be lower; e. g., in the greater Los Angeles area 8 of 687, or 1.2%, of routine premarital serums were positive.[5] The conclusion may fairly be drawn that there is Q fever in Utah but that the disease has, for the most part, not been diagnosed. Our patient's dramatic improvement with chloramphenicol therapy is testimony to the importance to the patient of considering Q fever in the differential diagnosis of pneumonia.

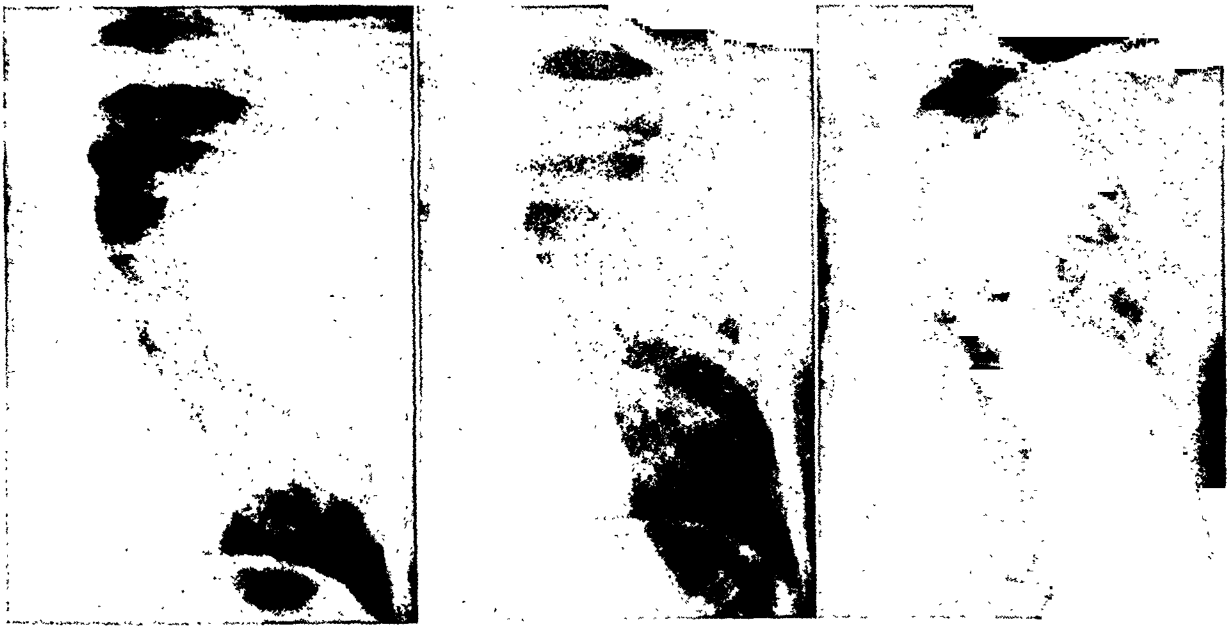

Fig. 1.—*Left*, a posteroanterior chest film taken at entry (sixth day of illness), disclosing homogenous density in left upper lobe. *Center*, considerable resolution on 15th day of illness, five days after chloramphenicol therapy was started. *Right*, continued but incomplete clearing of pneumonia of left upper lobe in film taken 32 days after onset of disease.

Q fever is caused by Rickettsia burneti. However, Q fever differs in many ways from the other rickettsioses. There is no distinguishing skin rash. Serums of patients convalescing from Q fever do not contain agglutinins for the Proteus species of the Weil-Felix test. Moreover, R. burneti is possessed of a tolerance to drying that is unique among the rickettsia. This environmental tolerance is likely associated with the epidemiology of Q fever.

It now appears that R. burneti is primarily a parasite of the tick. There is transovarial passage in the tick so that the association, tick-rickettsia, is not a mutually destructive one. Sheep, cattle, goats, and rodents are the usual mammalian extensions in habitat ventured by this micro-organism. Transmission to humans is a dead end for R. burneti, since human-to-human transmission does not occur. On the other hand, infection of domestic animals may lead to perpetuation and dissemination of mammalian parasitism, for R. burneti has been recovered from the milk of infected cows as well as from other secretions and excreta from a variety of infected animals.[2c]

For the most part, Q fever is clinically inapparent in sheep, cattle, and goats. However, there is serologic evidence that Q fever is spreading in cattle in the United States. In southern Idaho, spread has been noted particularly in dairy cattle [4b]; it remains to be seen whether an increase in human Q fever will follow.

Human Q fever is rarely, if ever, the result of a tick bite. The usual route of human infection is by inhalation of infected dust particles, for example, R. burneti–laden dust from detritus from hides or from wool.[6] Q fever in the human presents as an undifferentiated, or atypical, pneumonia. There are no characteristics which permit certain diagnosis on clinical grounds alone. Yet, with psittacosis, Q fever is remarkable for being a specifically treatable atypical pneumonia. Chloramphenicol, or one of the tetracyclines, will secure prompt amelioration of the disease, as demonstrated by the case reported here (fig. 2).

Course of Disease in Volunteers.—When untreated, the consequence of Q fever uncommonly is death but quite often is a significant morbidity. When studied in volunteers,[7] clinical Q fever resulted in 16 of 23 men exposed to various doses of aerosolized R. burneti (18 of these 23 men developed complement-fixing antibodies to Q fever). It must be kept in mind that Q fever induced in healthy young men by a laboratory strain of R. burneti may not be typical of the disease encountered in practice. For example, sudden onset of symptoms was not prominent and there were no instances of protracted disease (reported to occur in as many as 20% of patients with epidemic Q fever), of hepatitis, or of prolonged weakness and weight loss during convalescence in this volunteer study.[8] Yet, certain aspects of the clinical course in volunteers are of interest in that they probably refer to the situation in nature.

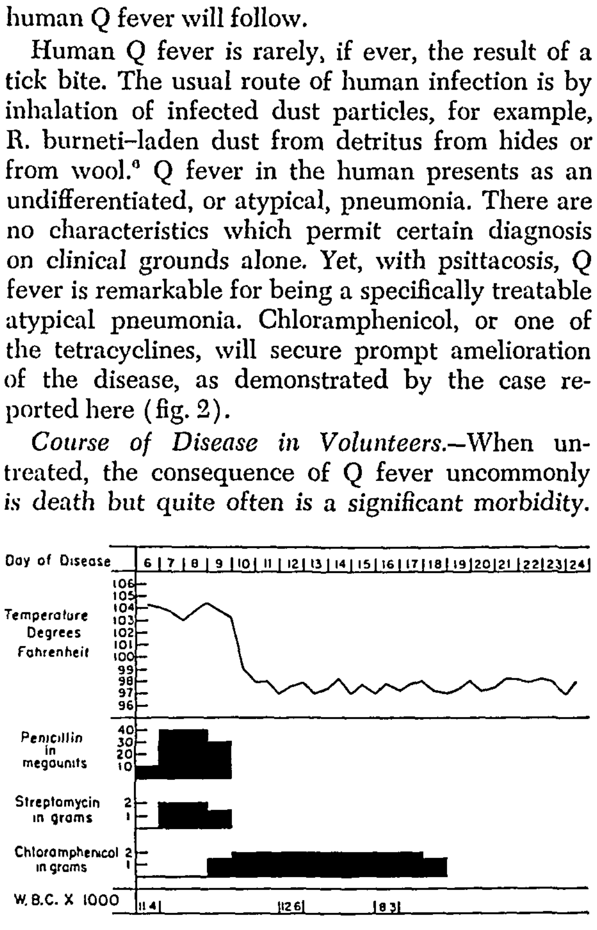

Fig. 2.—Graphic summary of clinical course of patient with Q fever. Dramatic defervescence and symptomatic improvement coincided with chloramphenicol therapy.

† Day of onset of symptomatic disease taken as 1st day of illness (Sept. 1, 1958).

‡ Titer expressed as reciprocal of highest dilution of serum yielding 4+ reaction.

Thus, although in this volunteer study the inhaled dose of R. burneti was increased 1,500 times from the smallest infecting dose, the incubation period decreased concomitantly only from 17 to 10 days. Low-grade fever with lassitude and anorexia marked the clinical onset of the illness. Real chills were rare, but temperature usually rose during the afternoon to around 103 (39.4 C) by midnight. Headache was a common complaint. Relative bradycardia and/or splenomegaly were sometimes observed. Physical signs of pneumonitis were not striking. About one-half of the men with clinical illness developed roentgenographic evidence of pneumonitis around the third or fourth day of illness.

Differential Diagnosis.—Diseases which may, on clinical grounds, be confused with Q fever include bacterial pneumonias, influenza, adenovirus respiratory infections, psittacosis, and primary atypical pneumonia. With bacterial pneumonias the onset with rigor, pleurisy, and productive cough is of differentiating value. In addition, there is the appearance of the patient with compromised respiratory movements and cyanosis. Leukocytosis is commonly marked. The finding of a bacterial pathogen on culture of the sputum is confirmatory.

Influenza, typically of sudden onset, with fever, headache, and cough, mimics Q fever closely. Very likely, the category "influenza" is the nominal repository of most of the Q fever which must occur in Utah—over 7,000 cases of influenza were reported in Utah in 1958, a nonepidemic year.[9] While pulmonary infiltration is radiographically present in about 50% of the cases of Q fever, pneumonia is not a manifestation of uncomplicated influenza. Diagnosis of influenza can be accomplished by virus isolation (throat washings) or by examination of acute and convalescent serums for hemagglutination inhibition.

With isolation of the adenoviruses, it has become apparent that at least some of the cold agglutinin-negative, streptococcus MG-negative, primary atypical pneumonias are due to adenovirus infection. Types 4 and 7 have been associated with roentgenographic evidence of pneumonias, as well as types 1, 2, 3, and 18.[10] Virus isolation (throat washings, stool) and/or serologic studies (acute and convalescent serums) are required for diagnosis.

Adenovirus infection, psittacosis, and primary atypical pneumonia are often clinically indistinguishable from Q fever. While Q fever and psittacosis are curable with chloramphenicol or the tetracyclines, adenovirus infection and primary atypical pneumonia are not amenable to presently available anti-infectious agents. Psittacosis, while an uncommon cause of pneumonia, may be a severe illness. Diagnosis is ordinarily made by complement-fixation testing of acute and convalescent serums. The response to appropriate antibiotic therapy is a therapeutic trial that is of value in diagnosis. Primary atypical pneumonia is distinguished by engendering the production of cold agglutinins and/or agglutinins for streptococcus MG.

Diagnosis of Q fever by isolation of R. burneti has been accomplished by inoculation of blood, sputum, spinal fluid, and urine obtained during the acute, febrile stages of the disease into guinea pigs or embryonated eggs. However, the agent is so infectious to laboratory personnel that diagnosis by isolation is rarely justified. Commonly, diagnosis is retrospective and is accomplished by demonstration of a rise in serum complement-fixing antibodies specific for R. burneti; an increase from no detectable antibody in a serum specimen obtained during the acute illness to a titer of 1:32, or higher in serum collected about two weeks later (convalescent specimen), is diagnostic. A series of serums is required when antibiotic therapy has been instituted. With specific therapy there may be several weeks' delay in antibody response, so that a diagnostic rise will not be apparent until six to eight weeks after onset of illness.[7] The complement-fixing antibodies are highly specific and may persist for years.

Summary

A case of serologically proved Q fever occurred in a young man who works in a plant processing sheep hides. Although this is the second proved case of Q fever in Utah, serologic evidence indicates Q fever is of both widespread and frequent occurrence in the state.

175 E. 21st South St. (15) (Dr. Hoeprich).

This study was aided in part by a grant from the National Institute of Allergy and Infectious Disease, United States Public Health Service.

THE TEETH IN OLD AGE.—When examining the mouth, it should be remembered that the presence or absence of teeth is more vital than the presence or absence of infection. Dyspepsia is commoner in the toothless than in those whose oral state is foul. Removal of infected teeth in old people only occasionally coincides with a turn for the better. Many elderly folk never get used to dentures, so that possession of false teeth does not always indicate their use for mastication. Some natural teeth in the jaw are worth more than a denture taken out of the mouth before meals.—Trevor H. Howell, Some Clinical Signs In Old Age: Some Practical Points in Geriatrics and Gerontology, Ed. 2, H. K. Lewis and Co. Ltd., London, 1950.

CLINICAL EXPERIENCE WITH A NEW ERYTHROMYCIN DERIVATIVE, ERYTHROMYCIN PROPIONATE

REPORT OF ONE HUNDRED FIVE CASES

Ian M. Smith, M.D.
and
William H. Soderstrom, M.D., Iowa City

The effects of orally administered erythromycin propionate have been observed in 105 patients. Most of them took it four times a day or every six hours in one or two capsules containing 0.25 Gm., and in a few cases this medication was continued as long as two months. The diseases treated were particularly those caused by Staphylococcus aureus, and the series included cases of pustular acne, furuncles, carbuncles, and pyodermas. Good results were obtained in 98 patients, 10 of whom had previously failed to respond to other forms of chemotherapy. Only eight patients had side-effects such as anorexia or vomiting, and diarrhea occurred in but one patient. This derivative, erythromycin propionate, has the advantage over the parent compound in that it produces higher concentrations in the blood after oral ingestion.

Erythromycin has been found to be an excellent antibiotic with few serious side-effects.[1] In a number of studies it has compared favorably with penicillin and other antibiotics in its clinical effectiveness. Among the minor side-effects, nausea and mild diarrhea have been noted. A disadvantage to the use of this antibiotic, as with others, is that a number of resistant staphylococcic strains have been found in hospital-acquired infections. It is possible that some of these infections would be amenable to higher blood levels of the antibiotic.

A new derivative of this drug, erythromycin propionate,[2] produces high blood levels within half an hour after ingestion and peak concentrations approximately four times those obtained with erythromycin tablets.[3] This compound, a true ester, produces higher blood levels than the more loosely bound erythromycin stearate,[4] which behaves like the base. With greater absorption it is possible that the minor gastrointestinal upsets from residual drug in the intestines might be avoided. Serum levels are more predictable than the widely variable levels found with coated-tablet erythromycin therapy.[3c] A third advantage is the rapidity with which high serum levels are obtained after oral medication.[5] A comparison of the antibacterial spectrum of erythromycin propionate with that of the parent compound has shown them to be identical.[6]

Acute and chronic toxicity studies in mice and rats have disclosed no pathological findings after large doses of the new ester. Higher serum levels are obtained in animals with the ester than with the erythromycin base because of its limited excretion in bile.[3a] In man very little degradation of the ester takes place in the body, as 80% of the erythromycin excreted in the urine is unchanged erythromycin propionate.[3a]

This paper deals with our clinical experience with erythromycin propionate in a variety of diseases, particularly those caused by Staphylococcus aureus.

Materials and Methods

Selection of Patients.—From July, 1958, to December, 1958, erythromycin propionate was given to patients seen in consultation by one of us (I. M. S.) and in the medical, dermatological, and orthopedic wards of the University Hospitals. Some patients were treated in the dermatology out-clinic and student health department. With the exception of some of the latter two groups, all patients had a routine physical examination, blood cell count, and urine examination. Forty-nine patients had a blood cell count after treatment with the drug. The group of patients was composed of 59 males and 46 females who ranged in age from 6 to 89 years. The 37 hospital inpatients were seen daily to evaluate the clinical response and to note side-effects. Follow-up cultures were taken where indicated.

Bacteriological Studies.—Blood, sputum, urine, and other cultures were done in either the routine bacteriological laboratory or the laboratory of the infectious disease division. Both the incorporation of antibiotics in blood agar plates and the disk method of performing sensitivity tests were used (see table). Cultures were obtained from all but five of our patients.

Therapeutic Regimen.—Erythromycin propionate was given orally in capsule form, 0.25 or 0.5 Gm. four times a day or every six hours in most cases.

From the Infectious Disease Division, Department of Internal Medicine, College of Medicine, State University of Iowa, and the University Hospitals. Dr. Soderstrom is a Staff Physician at the Veterans Administration Hospital.

Therapy was continued for a median period of six days, but in a few cases it was given for as long as two months.

Results

Pustular Acne.—Seven patients, aged 16 to 24 years, had clinical diagnoses of acne. Staph. albus was cultured from the lesions in four and Staph. aureus in two, with no growth from one patient's lesions. The therapy varied considerably: on the average 250 mg. three times a day was followed in four days by a period of the same dose twice daily for one to two weeks and then long periods with 250 mg. once daily. All the patients, with one exception, showed improvement. The one exception was a girl who developed nausea and vomiting after taking 1 Gm. of the medicament; it was then withdrawn. We feel that a more vigorous therapeutic regimen would be more successful in a shorter period of time.

Furuncles.—Twelve patients with bacteriologically confirmed furunculosis were treated for an average of seven days with 250 mg. of erythromycin propionate, given four times a day, with improvement in all. Three patients, however, had a recurrence of their boils, and in one case the staphylococci previously sensitive to erythromycin were now resistant. In three cases incision and drainage was necessary. Three other patients received, concurrently, intranasally given bacitracin.

Carbuncles.—Four men were treated for carbuncle with an average dose of 18 Gm. over a 14-day period. Two carbuncles had to be drained. All the patients did well and were apparently cured.

Stasis Ulcers Infected with Staphylococci.—Five patients (including two diabetics) with stasis ulcer (all were females aged 69-81 years) were treated with 10-25 Gm. of erythromycin propionate over a 10-to-25-day period. There was a clinical and bacteriological cure in four patients and marked improvement in one. Pinch grafting was also done in two. Two days after a 10-day course of therapy with the erythromycin derivative, one patient died after hematemesis. A postmortem study was not done. A detailed case history of this patient is presented below.

Miscellaneous Staphylococcic Pyodermas.—Eighteen patients, including three with postoperative wound infections, two with impetigo, and two with paronychia, were treated with 4 to 56 Gm. of erythromycin propionate over a 3-to-42-day period. There were 14 patients with clinical cures and 2 with improvement, both of whom had pyoderma gangrenosum and required prolonged topical and systemic therapy. One of the patients with paronychia had tularemia with secondary staphylococcic involvement; this case is discussed below.

Osteomyelitis.—An 8-year-old boy with acute osteomyelitis of the metaphysis of the right fibula and a subcutaneous abscess did well with surgical treatment followed by therapy with erythromycin propionate given four times a day for three weeks. Three women and three men with chronic osteomyelitis showed considerable improvement with an average treatment of 39 Gm. of erythromycin propionate over a 28-day period. (All but one of these patients had operative drainage as well.) As at least a two-month period of follow-up study has elapsed in five of these patients without recurrence, it is tempting to call them cured; at least the disease is arrested. One patient showed relapse four months after the end of treatment.

Staphylococcic Pharyngitis.—In three girls and five men, aged 18 to 31, acute pharyngitis was present and culture medium inoculated with throat swabs grew pure cultures of coagulase-positive hemolytic Staph. aureus. All these patients were treated with 250 mg. given four times a day for an average of four days, and all recovered uneventfully from their acute pharyngitis. One 26-year-old girl complained of mild drowsiness for three days with a feeling of drawing-in around the mouth and swelling of the eyes. There was no swelling of the eyes on examination, and the subjective feelings disappeared while the medication was continued.

Antibiotic Sensitivity of Strains of Staphylococcus Aureus Isolated from Patients

	% of Strains Resistant to				
Strains Tested, No.	Penicillin (1 and 10 Units/Cc.)	Streptomycin (5 and 50 Mcg./Cc.)	Tetracycline (5 and 50 Mcg./Cc.)	Chloramphenicol (5 and 50 Mcg./Cc.)	Erythromycin (1 Mcg./Cc.)
32	62.5				
31		35.5*			
29			48.3		
24				0†	
32					12.5

* 16.5% of the strains were only sensitive to 50 mcg./cc.
† 80% of the strains were only sensitive to 50 mcg./cc.

Streptococcic Pharyngitis.—Fourteen patients (seven males and seven females) with streptococcic pharyngitis were treated with an average dose of 7 Gm. of erythromycin propionate over a six-day period. All were cured without any side-effects. One patient had to discontinue treatment because of nausea and two or three loose stools daily.

In two further cases of pharyngitis no pathogenic bacteria were isolated. In one patient this therapy was discontinued after one day because of nausea and vomiting. Both patients recovered without other side-effects.

Pulmonary Infections.—In six patients with purulent bronchitis, Staph. aureus (2), beta hemolytic streptococci (1), and normal flora (3) were isolated from the sputum. All of them improved on an average dose of 8 Gm. of the antibiotic given for seven days. One patient had a residual dry cough. There were no side-effects.

Three patients with pneumonia were cured (one case due to Pseudomonas aeruginosa and two to Staph. aureus). One patient complained of epigastric distress. In one other patient, however, the pneumonia was a complication of bronchogenic carcinoma. He improved temporarily with treatment. A 45-year-old woman who had staphylococcic empyema complicating a preceding Escherichia coli empyema was much improved after 35 days of treatment with 2 Gm. daily. A 29-year-old woman with bronchiectasis and pansinusitis infected with beta hemolytic streptococci showed no change after two weeks' treatment, but she had anorexia and anxiety.

Sinusitis.—Three patients with chronic sinusitis were improved (one case each due to Staph. aureus, Staph. albus, and Diplococcus pneumoniae). Two of them had preceding infections with Candida albicans. One, with intestinal infection, had no exacerbation of his diarrhea while he took the medicament along with nystatin (Mycostatin). The other, a 41-year-old multipara, had vaginitis which increased slightly while the medicament was given despite use of nystatin suppositories. After a break in therapy, for this reason, further treatment led to increased improvement in the sinusitis. Later treatment with tetracycline, however, produced still more improvement in this chronic pneumococcic sinusitis. These patients had an average dose of 21 Gm. of erythromycin propionate over a 16-day period.

Miscellaneous.—In addition, four patients were treated with the ester but assessment of their results was complicated by the concurrent use of chloramphenicol or novobiocin. All but one of them were cured, and none had side-effects. One patient, a 64-year-old woman with a left frontal abscess caused by Staph. albus, did not improve. The organisms proved to be resistant to erythromycin, and she showed improvement on tetracycline therapy.

An interesting group of five patients was treated initially with an average of 5 Gm. of erythromycin base and was then switched to therapy with erythromycin propionate. Several preferred the propionate form of the drug over the enteric coated base because they were free from abdominal discomfort. Three other patients who had taken the erythromycin base in the past expressed the same preference. All the patients switched to therapy with erythromycin propionate were cured without side-effects.

Side-effects.—The over-all impression was that patients on therapy with this drug were remarkably free of discomfort and there were no serious side-reactions to worry the physician. No superinfection was found, except possibly a mild exacerbation of an already present vaginitis due to C. albicans. No allergic phenomena, such as skin eruptions, pruritus, anaphylaxis, or asthma, were seen. None of the patients developed clinical evidence of bone marrow damage. In 49 patients blood cell counts after therapy were normal. There was no clinical or laboratory evidence of interference with liver or renal function. No patients complained of deafness or vertigo. No drug fever was found.

Gastrointestinal side-effects were minor in degree. Four patients complained of anorexia, nausea, or vomiting, but in only two was it necessary to stop the drug therapy. Two other patients complained of epigastric distress; one experienced it particularly with his evening and early morning doses taken on an empty stomach. Both, however, were successfully treated. Two patients had two or three loose, brown, watery stools daily. We stopped treatment in one because of this; the case of the other is reported in detail below. In one case fatal hematemesis occurred two days after the end of a 10-day course of erythromycin propionate therapy. This is reported in case 3.

Report of Cases

Case 1.—A 29-year-old *veterinarian* had an *acute exacerbation of a chronic sinusitis* associated with acute laryngitis. He was coughing up a moderate amount of purulent sputum and had vague respiratory distress. Apart from purulent nasal discharge and sputum, physical examination was normal. A heavy pure growth of Staph. albus was obtained from the sputum and nasal swabs.

Because of a misunderstanding, he took 750 mg. of erythromycin propionate four times daily for three days. This caused diarrhea with gaseous, loose, watery, brown stools three times daily. After two days off the drug therapy he resumed treatment with 500 mg. four times a day without further distressing side-effects. The laryngitis, bronchitis, and sinusitis responded promptly to treatment.

Case 2.—A 24-year-old physician when out hunting found a sick rabbit at the side of the road. He killed it and later dissected it along with five other rabbits, and none had any sign of disease. Three days later he developed axillary lymphadenopathy with chills and fever. In one or two days he noticed painful subungual lesions, from which pus could be expressed, on his thumb and ring finger. From the third day after exposure until the fifth day he took 250 mg. of tetracycline four times a day and felt improved except for the local lesions on the fingers. Fourteen days after exposure he developed *fever and axillary pain for a second time.* Two days later his titer against Pasteurella tularensis was 1:80; nine days later it was 1:640; and a further seven days later it was 1:2,560. At the time of the relapse the finger lesions were secondarily infected with Staph. aureus resistant to erythromycin, penicillin, streptomycin, and tetracycline and sensitive only to high doses of chloramphenicol or novobiocin. This report was unfortunately mislaid, but the lesions healed rapidly when 500 mg. of erythromycin propionate was given four times a day for five days. On this medication the axillary adenitis and malaise disappeared. It is possible that his tularemia was cured. The patient was given the choice of continuing the erythromycin propionate therapy or switching to an agent of known antitularemia potency. He decided to stop the erythromycin propionate therapy and received streptomycin intramuscularly, 1 Gm. twice daily for two days and 0.5 Gm. twice daily for five days. During this period he returned to his work. Two days later subungual pus reappeared in the thumb. The strain isolated on this occasion had the same antibiotic sensitivities as the previous one. A further two days later he developed a nasal furuncle associated in eight hours with spreading cellulitis of the left maxillary area with swelling particularly in the infraorbital region. He was afebrile. He was readmitted to the hospital and treated with 500 mg. of chloramphenicol four times a day and 250 mg. of novobiocin four times a day. The first drug was given for 4 days and the second for 10 days, and intranasally given bacitracin was used concurrently. He recovered uneventfully.

Case 3.—A 74-year-old housewife fell and broke her hip. She was admitted to a local hospital and on the second day was febrile and mildly confused. On the third day she was admitted to the University Hospitals and closed reduction of her left hip was done. History-taking was difficult because of the patient's confusion. She was noted to have sinus tachycardia confirmed by electrocardiogram and to have a rectal temperature of 102 F (38.8 C). There was slight cardiac enlargement but no evidence of cardiac failure. Circulation time and venous pressure were normal. A varicose ulcer was present, and a culture showed hemolytic Staph. aureus resistant to penicillin and sensitive to erythromycin, tetracycline, and high levels of chloramphenicol or streptomycin. On the third day of her admission her temperature was 102.6 (39.1 C) rectally. She was treated with 250 mg. of erythromycin propionate given every six hours. While receiving this treatment over a 10-day interval, her varicose ulcer healed but she remained febrile with a leukocytosis. She continued to have tachycardia with hyperpnea and was disoriented but had no localizing neurological signs. Her tachycardia did not respond to digitalization. Two days after discontinuing her antibiotic therapy she vomited 300 cc. of coffee-ground vomit and died shortly thereafter. This patient died of an undiagnosed illness, and we are unable to say what part the antibiotic might have played in the hematemesis.

Case 4.—A 73-year-old woman was transferred to the University Hospitals from another hospital. Six months previously she had received a Whitman's arthroplasty for osteomyelitis. At the time of admission she had an abscessed hip and lobar pneumonia. Staph. aureus resistant to penicillin and sensitive to erythromycin, streptomycin, tetracycline, and a high concentration of chloramphenicol was isolated from the hip abscess and from the sputum. She improved steadily on therapy with 250 mg. of erythromycin propionate given four times a day over a 47-day period.

Case 5.—A 35-year-old laborer had had a history of chronic osteomyelitis since the age of 15. Nine days prior to admission at this hospital on Oct. 8, 1958, the patient developed pain in the anterior part of the left thigh. This was treated at his local hospital with rest and antibiotics without improvement. Physical examination on admission showed the left leg 4 in. shorter than the right, fusion of hip in 150 degrees flexion, and a 0.5-cm. deep sinus tract over the left greater trochanter. Treatment consisted of bed rest and novobiocin, 250 mg. every six hours for one week, and he was discharged on Oct. 15, 1958, improved.

Shortly after discharge the patient developed pain over the medial condyle of the left femur without joint pain. He was readmitted on Oct. 30, 1958. Physical examination at this time revealed local tenderness over the condyle with some inflammation and a temperature of 101.2 F (38.4 C). X-ray examination showed bony destruction of the affected area. The patient was treated with chloramphenicol and penicillin with transient subjective improvement. Three days after admission his temperature rose to 103.4 F (39.6 C). A greatly swollen knee, containing pus, developed, and culture showed hemolytic Staph. aureus sensitive to erythromycin, penicillin, streptomycin, tetracycline, and chloramphenicol at high levels.

An arthrotomy was done with instillation of triple sulfonamides. The patient continued to receive chloramphenicol with triple sulfonamides for two days with a slight improvement in his fever. Two days after the arthrotomy, chloramphenicol therapy was discontinued and that with erythromycin propionate was started with 500 mg. every six hours; triple sulfonamide treatment was continued an additional two days. On Nov. 10, 1958, a decompression osteotomy and drainage of the intramedullary canal was done. After this the patient became afebrile with good wound healing and minimal drainage. Twenty-six days after the start of therapy with the erythromycin derivative it was discontinued because of epigastric distress. Four days after this a low-grade temperature elevation was noted for four days. A reculture of the sinus drainage again grew hemolytic Staph. aureus; the sensitivities were unchanged. The patient was placed in a hip spica and discharged on therapy with erythromycin propionate, 500 mg. every six hours for five days. At the time of writing he is well.

Comment

Erythromycin propionate is useful in treatment of a number of common infections and has been effective in treatment of a number of less common and more serious infections. In our hands it has been particularly helpful in the treatment of staphylococcic disease. As its spectrum covers staphylococci, streptococci, and pneumococci, it should be useful in general practice.

Studies done by others have revealed early and predictably high levels of the antibiotic in the blood after oral administration. In our experience therapeutic success has been more consistent with this compound than with the parent erythromycin. Patients complain less of minor side-effects. Diarrhea occurred only once in our series, if one omits the case of overdosage. This is considerably less than the 7.6% reported with erythromycin base.[1b] The lack of superinfections is an additional benefit.

Several of the patients with furunculosis responded well to the treatment initially but later showed relapse. We have referred elsewhere[7] to the "ping-pong-like" transfer of staphylococci from carriers in the family group or from carriage areas in the patient and believe that these recurrences are due to an ignorance of this fact.

Patients with osteomyelitis often require prolonged treatment. This new drug appears to be useful for the treatment of this disease. The 74-year-old patient who died with hematemesis was already seriously ill and disoriented with fever, tachycardia, and hyperpnea of undiagnosed etiology. In the absence of an autopsy it would be unfair to attribute the hematemesis to the drug alone, although the aggravation of a preexisting lesion appears quite possible.

Summary

Erythromycin propionate was used in the treatment of 105 patients with a variety of common infections. Sixty-four patients had Staphylococcus aureus infections and 16 had beta hemolytic streptococcic infection. The remainder were caused by a variety of organisms. Good results were obtained in 98 patients (94%). Ten of them had previously failed to respond to other forms of chemotherapy. The strains of bacteria that were isolated were resistant to the drug after treatment in only two patients.

The average duration of treatment was 12 days, with a range of from 1 to 55 days. The highest dose given was 70 Gm. over a 35-day period. No cases of fungus or staphylococcic superinfection of the alimentary tract were found. The only side-effects were anorexia, nausea, vomiting, or diarrhea, one or other of which occurred in 7.6% of the patients. Diarrhea occurred in less than 1%. In only three cases was there any need to discontinue therapy because of the side-effects. There were no fatalities definitely attributable to the drug. We did not find any hypersensitivity or clinical or laboratory evidence of bone marrow, liver, or renal damage. In one patient a fatal hematemesis, not believed to be the result of the treatment, occurred two days after the end of a course of therapy. The drug is considered to be useful and convenient in treatment of a number of common infections.

This study was aided, in part, by a grant from Eli Lilly & Company, Indianapolis. The erythromycin propionate used in this study was supplied as Ilosone by that company.

Miss Marion Jones, M.Sc., supplied the reports from the bacteriological laboratory. Drs. Mary E. Godfrey, Ellia Ch. Hazard, William B. Bean and staff, L. Boulware, Carroll B. Larson and staff, Chester I. Miller, Chris E. Redcliffe, and P. C. Stivrins aided in this study.

CLINICAL NOTES

EWING'S SARCOMA OF THE TOE

Albert R. Andrisek, M.D., Cleveland

A review of the literature regarding Ewing's sarcoma indicates that tumors located in small bones are apparently a rare finding. In 75% of cases, long bones of the extremities, including the shoulder girdle, were involved; lower extremities were involved in 50% of cases. The predilection for metaphysis in long bones was noted. In the series reported by McCormack, Dockerty, and Ghormley[1] no cases of phalangeal tumors are reported. In a study of 424 primary malignant tumors of the bone, Meyerding[2] found that Ewing's sarcoma of all bones constituted approximately 27%.

The condition is rare. At the Mayo Clinic, primary bone tumors occur in about 1 in 10,000 patients. The only case seen in a phalanx of the toe is reported by Geschickter (tumor of bone, 1930). He mentions a few that were located in the tarsus and metatarsus. There is a report[3] of Ewing's sarcoma of the cuneiform bone in a 14-year-old boy, who remained well for two years after amputation below the knee and finally developed pulmonary metastases. No other cases of Ewing's sarcoma in small bones could be found in the medical literature since 1945.

Ewing's sarcoma is a disease of childhood and adolescence; more than half of the cases occur in persons under 20 years of age and 80% in persons under 30 years of age. Males are affected twice as often as females. The onset of this disease is insidious; aching, boring pain is generally the first symptom. The pain rapidly increases in persistence and severity, being accentuated during rest. Roentgenologic findings are not as typical or diagnostic as some of the literature might lead one to expect.

Report of a Case

A 20-year-old male was seen for a routine examination on Sept. 24, 1954, at which time he complained of pain and redness of the large toe, right foot, which had been present for about two weeks. He thought he might have stubbed the toe but was not certain. He admitted having partaken in some beer drinking and wondered if he might not have gout.

The patient's history included the usual childhood diseases, ruptured appendix, and tonsillectomy. Physical findings on examination were essentially negative, except those of the large toe, which appeared reddened and tender under pressure, with some swelling and apparent induration. An x-ray of the toe (fig. 1), on Sept. 24, showed dense proliferation of the proximal phalanx. X-rays of the hands, left foot, pelvis (both hip joints), and chest were negative. The laboratory report showed uric acid level, 6.2 mg. per 100 cc.; hemoglobin level, 15.0 Gm. per 100 cc.; white blood cell count, 6,700 per cubic millimeter; and differential count within normal limits.

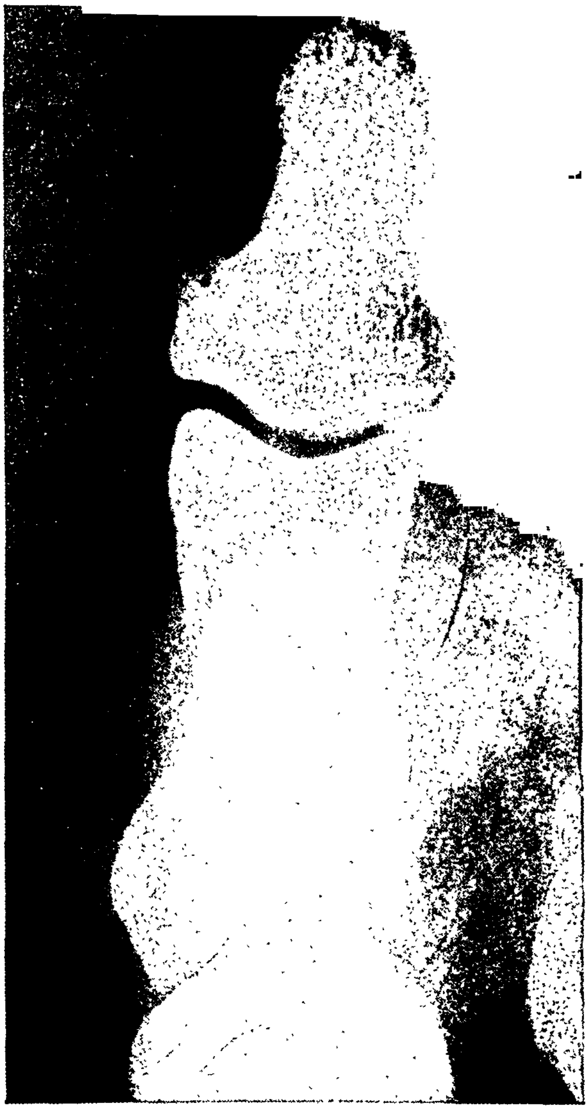

Fig. 1.—X-ray of right great toe, showing dense periosteal proliferation of proximal phalanx.

From St. Vincent's Charity Hospital.

A biopsy (fig. 2) was done on Oct. 6, 1954. Grossly the tissue fragments varied from 0.5 to 2 cm. in greatest dimension. They were light tan to gray and sectioned with moderate resistance. The cut surfaces were smooth and glossy. Some of the fragments were friable and soft.

Microscopic sections revealed thick anastomosing cords and sheets of small cells forming broad collars around small vascular spaces. The cells were fairly uniform in size, shape, and staining quality. They displayed scanty pale pink to stainless cytoplasm with indefinite cell borders. The nuclei were prominent, oval to round, and occasionally irregular. They varied slightly in staining quality but in general were pale with somewhat darker borders. Occasional nucleoli were identified, and mitotic figures were not infrequent. The cells were compact in some areas but more loosely arranged in others. While they surrounded vascular spaces, they did not encroach on the walls of the blood vessels, whose lumens were free of tumor cells. Formations of fibrous septums occasionally gave the tumor an alveolar appearance.

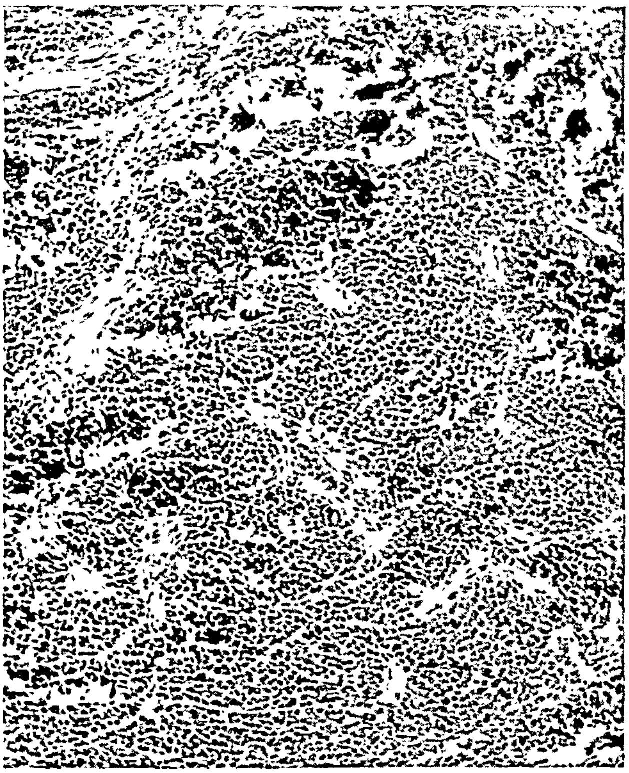

Fig. 2.—Biopsy specimen of proximal phalanx of right great toe.

Decal sections showed thick bony trabeculae surrounded by fibrous tissue infiltrated by loosely arranged nests of tumor cells. Occasional cells infiltrated marrow spaces which were undergoing fibrosis. No multinucleated giant cells of tumor origin were identified. A diagnosis of Ewing's sarcoma was made.

Disarticulation of the proximal phalanx with removal of one-third of the metatarsal was done on Oct. 11, 1954.

On Feb. 2, 1955, the patient complained of pain in right groin and over the right femur anteriorly. X-rays taken on Feb. 22, 1955, were negative. X-rays taken on June 18, 1955, showed metastasis to the right hip joint and left ribs (fig. 3 and 4). On June 24 palliative x-ray therapy (250 kv. to th right hip and ribs) was begun; it was continued to Oct. 3 1955, with a partial response and with decrease in the siz of the lesion and some alleviation of pain. On Jan. 8, 1956, metastasis to the left temperoparietal bones was noted. On Jan. 13, 1956, the patient died.

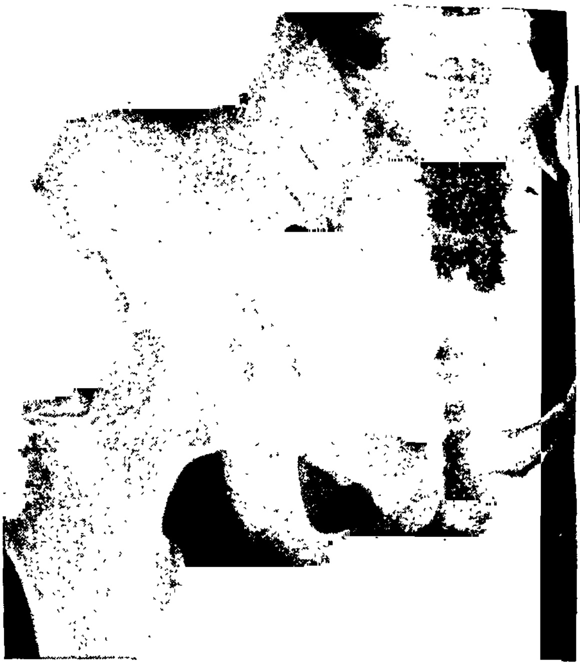

Fig. 3.—X-ray showing metastasis to right hip.

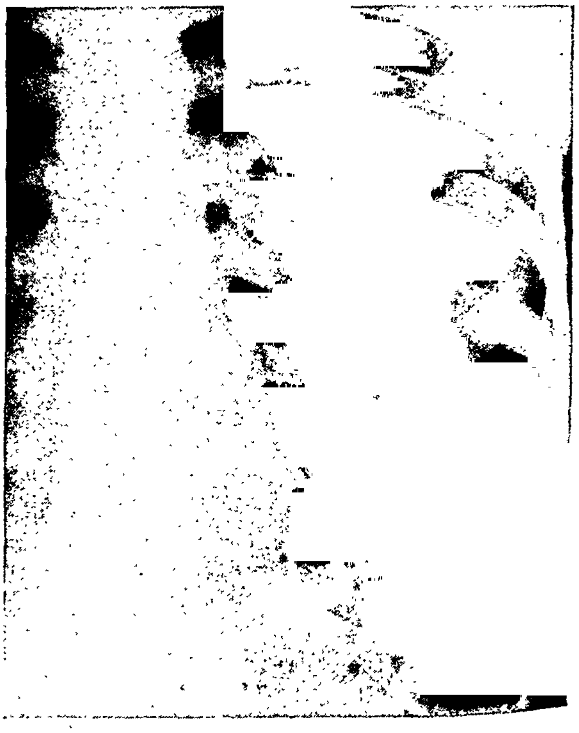

Fig. 4.—X-ray of chest, showing metastasis to ribs.

Comment

Since the etiology is obscure and the disease is primarily of childhood, youth, and early adult life, rarely seen in persons over the age of 25, the clinical features of pain, variable in intensity with a lump or swelling, can be confused with a bone infection.[4] Primary bone sarcoma of a phalanx is so rare as to be considered almost nonexistent.[5] Unfortunately, despite the control of the primary tumor, metastases nearly always develop later. Though these in turn yield to treatment, the patient dies during the continuing hopeless struggle to keep up with the widespread disease by radiation therapy. The progress of the disease varies markedly, being exceedingly rapid in some cases while in others a fatal termination may be long deferred. The average life expectancy is usually less than two years.

Summary

A case of Ewing's sarcoma has occurred, with reactive bone formation in sun ray pattern as seen in figure 1. An extensive but incomplete survey of the literature has disclosed only one case of Ewing's sarcoma of the phalanx, reported by Geschickter. Metastasis is rapid, with death occurring between two and five years after onset of the disease.

2939 Woodhill Rd. (4).

Dr. E. J. O'Malley assisted with x-ray interpretation and therapy in this study. Dr. Wm. Hoffman made pathological interpretations and studies, and Miss E. Slusarczyk assisted with the statistical analysis.

PERICARDITIS IN ASSOCIATION WITH CHICKENPOX

Theodore Mandelbaum, M.D., Rockville Centre, N. Y.
and
Byron H. Terk, M.D., Hempstead, N. Y.

The occurrence of pericarditis in association with acute infectious disease is not uncommon and has been reported frequently in the past decade.[1] Griffith and Wallace,[2] in 1953, reported on the etiology of pericarditis and recorded 15 different causes for this disease; the highest percentage (15.8) of cases is classified as being due to idiopathic disease. They make no mention of chickenpox (varicella) as a causative agent. In other reports,[3] a relationship between viral disease and pericarditis of the so-called benign nonspecific type has been definitely established. Up to now, there have been no reports in the literature showing the coexistence of pericarditis with chickenpox; however, the presence of myocarditis with chickenpox is not unknown. Hackel[4] described seven cases of chickenpox ending fatally in which the autopsy reports showed myocarditis not suspected clinically. Epicarditis also was demonstrated to a moderate degree in six of these cases. It is therefore considered of interest to report the following case, which appears to be clinically typical of acute benign pericarditis occurring during the course of an illness diagnosed as chickenpox.

Report of a Case

A 33-year-old male was admitted to Meadowbrook Hospital with a two-day history of malaise and fever, and a 12-hour history of headache, photophobia, and skin eruption. The eruption was first noted on the head and almost simultaneously on the face, neck, and upper extremities. There were no other systemic or local symptoms. The patient's son had had chickenpox three weeks prior to the present illness. The patient had never had chickenpox and had been vaccinated twice for smallpox, once as a child and once while he was in the armed services, in 1943.

On his admission to the hospital, the patient's temperature was 102 F (38.9 C); he was uncomfortable but in no acute distress. The skin was the site of a macular, papular, vesicular, and rarely pustular rash in all stages of development. This rash was present on the scalp, face, arms, legs, and torso.

From the Division of Internal Medicine, Meadowbrook Hospital, Hempstead, N. Y.

The lungs were clear to auscultation and percussion. The heart was not enlarged; there were no murmurs or thrills. The remainder of the physical examination was not remarkable.

Treatment initially was only symptomatic. The temperature continued to be elevated to approximately 101 F (38.3 C), and the clinical course was uneventful until the second hospital day, at which time he suddenly complained of severe aching pain in the left anterior part of the chest, with radiation to the back, neck, and upper part of the left arm. Extreme restlessness without diaphoresis or cyanosis soon appeared. The pain was not increased by respiration or motion. The pulse was 70 beats per minute; the blood pressure was 130/90 mm. Hg. The heart sounds were somewhat distant, but murmurs or friction rubs were again not discernible. The lungs were clear to auscultation and percussion. There was no local muscular tenderness. An electrocardiogram taken shortly thereafter revealed regular sinus rhythm, elevation of the S-T segments in leads 2, 3, and aVF, and depressed S-T segments in aVR, aVL, V_1, and V_2, with inverted T waves in V_1, V_2, and V_3 (fig. 1). Following the onset of these symptoms, the blood pressure dropped to a low of 80/50 mm. Hg during the next six hours but subsequently rose to 100/60 and remained elevated until the patient's discharge. An electrocardiogram taken 18 hours later showed a return to normal of the S-T segments. The patient had a similar attack of pain on the third hospital day, at which time a third electrocardiogram was made.

A chest film revealed the aorta arching to the right, which was confirmed by barium swallow, but otherwise there was no enlargement or other abnormality. The white blood cell count ranged from 6,000 to 6,400 per cubic millimeter on the first, second, and fourth hospital days. After initial polymorphonuclear cytosis, the remaining white blood cell counts revealed lymphocytosis. The sedimentation rate was 17 mm. per hour on the second hospital day and 35 mm. on the fourth hospital day. The fasting blood sugar level was 86 mg. per 100 cc., the cholesterol level 196 mg., and the blood urea nitrogen level 16 mg. Serial electrocardiograms show the progressive changes one would expect to find associated with an acute pericardial disease. Figure 2 is a tracing taken after the second attack and shows T-wave changes further suggesting the presence of localized pericarditis. The tracing done three days after this one showed definite retrogression of the previous findings (fig. 3), and the final electrocardiogram, taken seven weeks later, shows a complete return to normal.

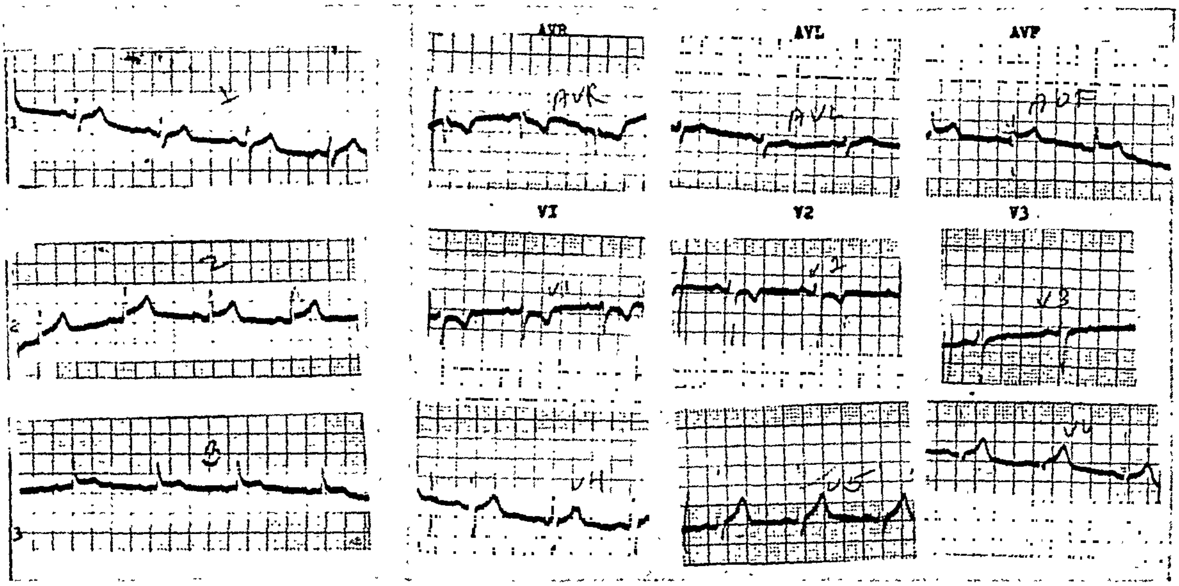

Fig. 1.—Electrocardiogram taken at onset of precordial pain, showing S-T and T-wave changes compatible with diagnosis of acute pericarditis.

The patient had become afebrile and insisted on signing his release on the eighth hospital day. He reported once more to the clinic seven weeks after his discharge, and his course has not been followed since.

Comment

This case is a classic one of chickenpox, with a typical history of exposure to that disease, the subsequent development of the characteristic exanthema, and the final retrogression of all signs and symptoms. However, shortly after the onset of the rash and fever the patient developed sharp chest pains, further increasing malaise, a decreasing blood pressure, and electrocardiographic changes interpreted as being those associated with pericarditis. A recurrence of his complicating discomfort reappeared in two days, with additional confirmatory electrocardiographic findings; such recurrence is not uncommon with viral (benign) pericarditis and has led to the use of the term "acute relapsing pericarditis."[1e] The rather rapid and relatively complete disappearance of all evidences of pericarditis is an expected result. Although this case did not present all of the classic phenomena that occur with so-called viral pericarditis, there appear to be enough changes to establish this diagnosis: the typical clinical course as manifested by the nature of the complaints, its acute onset, its subsidence, and its recurrence associated with the characteristic electrocardiographic changes. The fact that a friction rub was not heard and that cardiac enlargement was not noted merely suggests that the pericardial involvement was not of sufficient degree to produce pericardial effusion. The absence of changes in the quality of the heart sounds or in the rhythm indicates that myocarditis was not present to any detectable or significant degree.

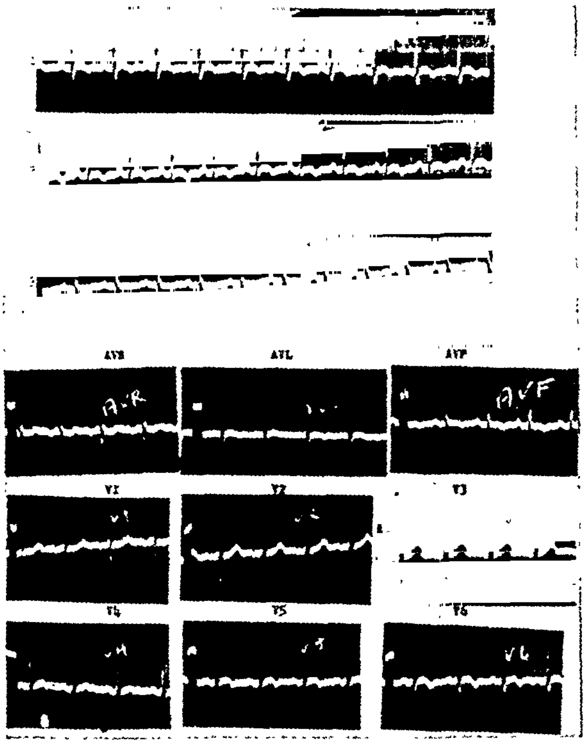

Fig. 2.—Electrocardiogram taken following second attack of precordial pain, showing even more pronounced T-wave changes.

Despite the frequency of the occurrence of pericarditis in relationship to acute infectious diseases, including those of so-called viral origin, it is interesting that no clinical cases of chickenpox pericarditis have been previously reported. It must be presumed that the association of these two phenomena is not unexpected; this has been demonstrated pathologically by Hackel.[4]

Usually acute pericarditides have been described as being the result of the primary inflammatory condition. Congenital abnormalities apparently may occur as a fortuitous circumstance and do not predispose to the appearance of a complicating inflammatory process involving the heart or surrounding structures. It is therefore felt that the arching of the aorta to the right described in this individual probably has no direct or indirect bearing on the occurrence of the acute disease as reported in this case.

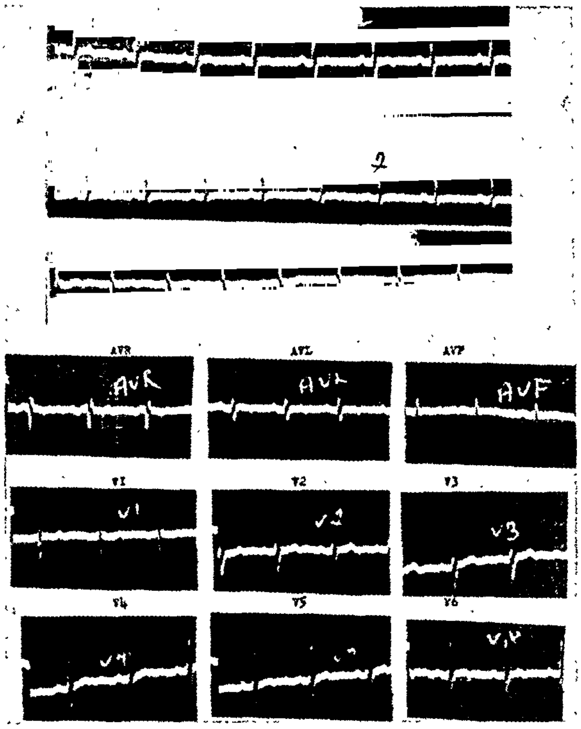

Fig. 3.—Repeat tracing done three days after last occurrence of precordial pain, showing less-pronounced T-wave changes.

Summary

In a case of acute benign pericarditis in association with chickenpox, the chickenpox was of classic course and was complicated only by the appearance of pericarditis of approximately four days' duration, with electrocardiographic changes lasting over a period of at least one week. The resolution was found to be complete on the examination done seven weeks after the onset of the acute illness.

165 N. Village Ave. (Dr. Mandelbaum).

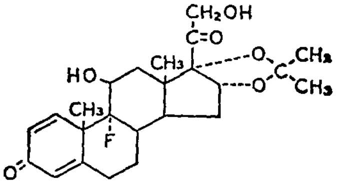
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. KAUTZ, M.D., *Secretary.*

Triamcinolone Acetonide (Kenalog).—9α-Fluoro-16α, 17α-isopropylidenedioxy-Δ^1-hydrocortisone.—The structural formula of triamcinolone acetonide may be represented as follows:



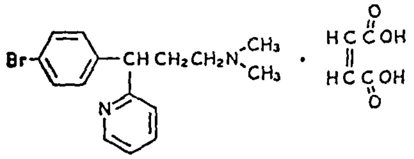
Actions and Uses.—Triamcinolone acetonide, a ketal derivative of triamcinolone, is a highly potent synthetic glucocorticoid which was introduced in 1958 for topical use in the treatment of certain acute or chronic dermatoses. It is effective in much smaller doses than those required with hydrocortisone acetate and shares the same relative freedom from untoward local and systemic effects. The drug is useful for the control of many common dermatoses, allergic and inflammatory, especially those associated with pruritus. Among these are atopic and contact dermatitis, neurodermatitis, seborrheic dermatitis, nummular eczema, eczematous dermatitis, exfoliative dermatitis, anogenital pruritus, and pruritus with lichenification. The drug may also be of value in relieving itching and burning associated with insect bites. Although it has occasionally proved beneficial in the management of eczematized psoriatic lesions (e. g., intertriginous psoriasis), the evidence to date does not suggest any consistent effect in chronic lichenified psoriatic lesions.

With the usual therapeutic doses systemic steroid effects have not been observed. Local irritation has rarely occurred, and, when it has, it may have been due to the vehicle in which it was incorporated rather than to triamcinolone acetonide per se. As with other steroid compounds, the drug should not be applied to infected areas of skin unless appropriate topical or systemic antibiotics are used concomitantly.

Dosage.—Triamcinolone acetonide, in concentrations of 0.1%, is applied topically to the affected areas two or three times daily.

Preparations: cream 0.1%; lotion 0.1%; ointment 0.1%. E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of triamcinolone acetonide.

Brompheniramine Maleate (Dimetane).—2-[*p*-Bromo-α-(2-dimethylaminoethyl)benzyl]pyridine maleate.—The structural formula of brompheniramine maleate may be represented as follows:



Actions and Uses.—Brompheniramine maleate, introduced commercially in 1958, is a potent antihistaminic agent with actions and uses similar to those of chlorpheniramine maleate, to which it is chemically related, the difference being the substitution of a bromine atom for the chlorine atom of the latter compound. (See the monograph on chlorpheniramine maleate and the general statement on histamine-antagonizing agents in New and Nonofficial Drugs.) Brompheniramine exhibits a high order of antihistaminic effectiveness and a low incidence of side-effects. Thus, it has a relatively large margin of safety. The drug is also suitable for parenteral administration.

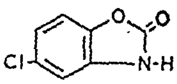
Dosage.—Brompheniramine maleate is administered orally or by subcutaneous, intramuscular, or intravenous injection. For adults, the usual oral dose is 4 mg. three to six times daily. Alternatively, a sustained release tablet containing 12 mg. may be taken every 8 to 12 hours or twice daily. For children over 6 years of age, the oral dose is one-half of that outlined for adults. Doses of 2 mg. given three times a day are usually adequate for children under 6 years of age.

For parenteral administration by the subcutaneous, intramuscular, or intravenous routes, the usual dose of brompheniramine maleate ranges from 5 to 20 mg., with an average of 10 mg. No more than 40 mg. of the drug should be given parenterally in a 24-hour period. When given intravenously, the drug should be injected slowly in a solution no more concentrated than 10 mg. per cubic centimeter. For use in reducing the danger of transfusion reactions, 10 mg. of the drug may be mixed with blood at the time of transfusion, or 10 mg. may be injected intravenously. Sterile solutions of the drug can be mixed with isotonic sodium chloride or 5% dextrose injections, but they should not be allowed to stand in contact with antigenic material used in hyposensitization procedures.

Preparations: elixir 0.4 mg. per cc.; solution (injection) 10 mg. in 1 cc., 200 mg. in 2 cc.; tablets 4 mg.; tablets (sustained release) 12 mg.

A. H. Robins Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of brompheniramine maleate.

Chlorzoxazone (Paraflex).—5-Chloro-2-benzoxazolinone.—5-Chlorobenzoxazolinone.—The structural formula of chlorzoxazone may be represented as follows:



Actions and Uses.—Chlorzoxazone, introduced in 1958, is a skeletal muscle relaxant with actions and uses similar to those of zoxazolamine, of which it is a derivative. Chlorzoxazone produces higher blood levels after oral administration than does zoxazolamine. It does not have the uricosuric activity exhibited by zoxazolamine. The drug is used in the same manner as zoxazolamine for the treatment of painful muscle spasm associated with certain musculoskeletal disorders. These include low back pain, fibrositis, bursitis, myositis, spondylitis, sprains, muscle strains, and torticollis. It may also be employed in conjunction with analgesics (salicylates) and other forms of therapy for the symptomatic treatment of spasm in rheumatoid arthritis and osteoarthritis. Current evidence indicates that chlorzoxazone is of the same order of effectiveness as zoxazolamine for these musculoskeletal disorders. The drug may have some limited value as an adjunct to other therapy in the management of cervical root syndrome and disk disorders. There is little evidence that chlorzoxazone is of any appreciable benefit in spasticity of neurological origin such as in cerebral palsy, dystonia musculorum, amytrophic lateral sclerosis, and multiple sclerosis. Like zoxazolamine, the drug has not been of value in paralysis agitans (Parkinson's disease), various pyramidal tract lesions, basal ganglion disorders, or epilepsy.

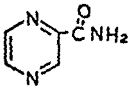
In general, the clinical toxicity of chlorzoxazone is less than that of zoxazolamine, which is the principal distinguishing feature between the two drugs. Side-effects, which are reversible and seldom require the discontinuance of medication, include occasional instances of nausea and vomiting, heartburn, abdominal distress, constipation, and diarrhea. Central nervous system effects may include dizziness, lightheadedness, drowsiness, overstimulation, headache, lethargy, or malaise. Although not frequent, hypersensitivity reactions of the skin may occur; the drug should be discontinued if pruritus or urticaria develops.

Dosage.—Chlorzoxazone is administered orally in doses which must be individualized according to the severity of the symptoms under treatment and the response of the particular patient. For adults, dosage ranges from 250 to 750 mg. three or four times a day. Dosage for children is reduced according to age and body weight.

Preparations: tablets 250 mg.

McNeil Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of chlorzoxazone.

Pyrazinamide (Pyrazinamide).—The structural formula of pyrazinamide may be represented as follows:



Actions and Uses.—Pyrazinamide, introduced in 1955, is a potent, synthetic, antituberculosis agent. Its tuberculostatic activity, as indicated by its ability to eradicate viable tubercle bacilli in mice, is less than that of streptomycin or isoniazid but greater than that of aminosalicylic acid. Pyrazinamide is probably more active also than either cycloserine or viomycin.

Because of its potential toxicity and relatively short period of effectiveness, pyrazinamide is considered one of the secondary drugs for the chemotherapy of tuberculosis. It is best reserved for seriously ill hospitalized patients with tuberculosis that has ceased to respond to one or more of the major chemotherapeutic agents and combinations, i. e., streptomycin, isoniazid, and aminosalicylic acid. Short-term coverage of surgical procedures to minimize or prevent the spread of infection or occurrence of other tuberculous complications is currently the chief indication for pyrazinamide. Occasionally, the drug can be used in medical emergencies for the treatment of gravely ill patients who are intolerant, by reason of acquired allergies, to other chemotherapeutic agents. Pyrazinamide is not recommended in the initial therapy of newly discovered or previously untreated cases of tuberculosis.

When pyrazinamide is used alone, organismal resistance to its tuberculostatic action develops rapidly (within six to seven weeks), rendering further use of the drug ineffectual. For this reason, there is no indication for the long-term use of pyrazinamide alone in tuberculosis.

Since past experience shows that combined anti-infective therapy is usually superior in the treatment of tuberculosis to therapy with a single drug, the question arises as to the desirability of combining pyrazinamide with other agents. Current opinion seems to be fairly well divided on this issue. When high (and potentially toxic) doses of pyrazinamide are combined with the usual doses of isoniazid, there is some evidence to suggest a synergistic action, which may provide a higher degree and a longer period of chemotherapeutic effectiveness. Such salutary effects are not observed when the dose of pyrazinamide is low. On the contrary, there is a possibility that small amounts of pyrazinamide may even interfere with the chemotherapeutic effectiveness of isoniazid. On the basis of present evidence, the use of pyrazinamide alone, given briefly before and after operation, seems to be justified solely as a means of protecting tuberculous patients against the complications of chest surgery. The ultimate value of pyrazinamide in combination with other drugs must await the results of further investigations.

Hepatic damage, with or without jaundice, has been a serious untoward reaction which has limited the usefulness of pyrazinamide. Although signs of impaired liver function often disappear upon discontinuance of medication, the damage may be progressive and irreversible and may result in death. It is estimated that jaundice occurs in about 3% of patients receiving this drug and that abnormal liver function tests are demonstrated in about 10 to 15% of patients with or without jaundice. Hence, pyrazinamide should be used only when close observation of the patient is possible (preferably in a hospital) and when adequate facilities are available for reliable liver function tests. Sulfobromophthalein retention, serum bilirubin values, thymol turbidity or cephalin flocculation tests, and serum glutamic oxalacetic transaminase determinations, as well as an examination of the urine for bile, should be carried out prior to initiating therapy in order to obtain base-line values. These tests should then be repeated at frequent intervals during therapy. The physician should realize that, while liver function tests are helpful, hepatic damage may occur with explosive suddenness. Hence, close clinical observation, with daily examination for liver enlargement or tenderness and jaundice, is imperative.

Since the drug may cause retention of uric acid in occasional patients, routine blood uric acid determinations may also be indicated; in several instances, an acute attack of gout has occurred during or after the period of pyrazinamide administration.

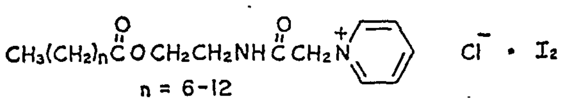
Relatively minor and infrequent side-effects to pyrazinamide include anorexia, gastrointestinal disturbances, joint pains, malaise, nervousness, dysuria, and mild febrile reactions. These effects seldom require discontinuance of therapy.

Dosage.—Pyrazinamide is administered orally. The suggested total daily dose, given in three or four divided doses, is 35 mg. per kilogram of body weight. Although some authorities advocate larger amounts (40 to 50 mg. per kilogram), it is generally agreed that the maximum daily dose, regardless of weight of the patient, should not exceed 3 Gm. When used to cover the surgical management of tuberculosis, therapy with this drug should be started one to two weeks before operation and continued through the operative period and for postoperative periods ranging from two weeks to two months.

Preparations: tablets 500 mg.

Merck Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of pyrazinamide.

Undecoylium Chloride-Iodine (Virac).—A complex of iodine with the quaternary compound, acylcolaminoformylmethylpyridium chloride, the acyl group of which is a mixture containing 8 to 14 carbon atoms but principally a 10 to 11 carbon chain. The structural formula of undecoylium chloride-iodine may be represented as follows:



Actions and Uses.—Undecoylium chloride-iodine, a complex of iodine and a cationic quaternary detergent, was introduced commercially in 1957 for topical use as a germicidal agent. Although the detergent itself has some antiseptic properties, the antimicrobial activity of the complex is derived almost wholly from the elemental iodine which is slowly released upon contact with skin and mucous membranes. The wetting action of the detergent does, however, facilitate contact of the iodine with surface areas. Since the iodine complex is water-soluble, it does not precipitate with tissue proteins as do iodine tinctures.

Undecoylium chloride-iodine is used for the prophylaxis and treatment of surface infections due to organisms susceptible to the germicidal action of iodine. However, it cannot be used in place of good surgical judgment in the management of puncture wounds or other wounds containing devitalized tissue. To date, it has been employed for preoperative and postoperative disinfection of the skin, perineum, and genital tract, for the treatment of contaminated wounds and cutaneous bacterial infections, as a douche for the control of vaginal trichomoniasis and moniliasis, and for the treatment of fungus infections of the scalp and feet. It is of the same order of effectiveness as other preparations containing iodine. In contrast to tinctures or solutions of elemental iodine, however, the complex does not cause stinging or irritation to the skin or mucous membranes. In addition, it does not stain skin or clothing. The sensitizing potential of undecoylium chloride-iodine is not known, but, on the basis of experience to date, it appears to be quite low. This possibility should be considered in patients with known sensitivity to iodine.

Dosage.—Undecoylium chloride-iodine is applied topically as needed, generally as an aqueous solution containing 0.2% available iodine. For preoperative disinfection of the skin, more concentrated solutions may be used. Because the complex is detergent, it may be used alone as a shampoo for the treatment of scalp infections.

Preparations: solutions (topical) containing 0.2, 0.6, 0.8, and 3.2% available elemental iodine.

Ruson Laboratories cooperated by furnishing scientific data to aid in the evaluation of undecoylium chloride-iodine.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following report.

PHILIP L. WHITE, Sc.D., *Secretary.*

METABOLISM AND CALORIC VALUE OF ALCOHOL

Wilfred W. Westerfeld, Ph.D.
and
Martin P. Schulman, Ph.D., Syracuse, N. Y.

Not only has alcohol been a controversial subject philosophically but also the scientific literature has been full of conflicting conclusions. Our knowledge of the absorption, distribution, and excretion of alcohol is well founded and generally accepted. The pathway of alcohol metabolism has been assumed on the basis of indirect evidence without much argument, but at the present time the exact pathway by which alcohol is metabolized is still uncertain. The utilization of alcohol as a food and the complications of its excessive use are only partially understood. We do not know what the phenomena of intoxication and tolerance can be attributed to, but we do know some of the things to which they cannot be attributed.

In this review of the subject, the extensive literature cannot be cited in detail, but appropriate reviews are given in the bibliography.[1]

Metabolism of Alcohol

Alcohol is neither selectively excreted, stored, or converted to a storage form in the body nor does any major portion accumulate as fat, protein, carbohydrate, or other tissue constituent. From studies with alcohol labeled with radioactive carbon (C^{14}), more than 90% of the isotopic carbons appear as carbon dioxide by the time the alcohol has disappeared from the blood. The blood alcohol rises to a maximum during the absorption phase. After distribution and equilibration with the tissues, the blood alcohol concentration decreases lineally with time as it is metabolized. Most substances have an exponential disappearance curve, and alcohol is an unusual metabolite in this respect. A linear disappearance curve results from a saturation of the enzyme, alcohol dehydrogenase, at low concentrations of alcohol, and higher substrate concentrations per se cannot increase the rate of the reaction. At blood alcohol concentrations below 0.01% (10 mg. per 100 ml.), the disappearance curve becomes exponential because the enzyme is no longer saturated with substrate.[2]

From the Department of Biochemistry, State University of New York, College of Medicine at Syracuse.

Absorption.—As a small, neutral, water-soluble molecule requiring no digestion, ethyl alcohol can be absorbed by simple diffusion throughout the entire gastrointestinal tract, including the stomach and rectum. Orally ingested alcohol is usually passed rapidly down the gastrointestinal tract from the stomach, and approximately 80% of it is absorbed from the small intestine as rapidly as it leaves the stomach. It passes into the blood at a rate proportional to its concentration, and since there is no upper limit to its rate of absorption, alcohol does not remain or accumulate in the intestine. Absorption can be slowed by delaying the emptying time of the stomach, as by consuming food, or by ingesting dilute instead of moderately concentrated (30%) alcohol solutions; for example, beer instead of cocktails.

Alcohol also is absorbed very rapidly from the peritoneal cavity, and it can slowly be administered intravenously as a 20 to 25% solution. It can be an industrial hazard since it is absorbed through the lungs, and intoxicating blood levels can be achieved through the prolonged inhalation of low concentrations of alcohol vapors. Alcohol is not absorbed significantly through the skin.

Distribution.—The distribution of alcohol throughout the body is in proportion to the water content of the various tissues. At equilibrium, most organs contain from 70 to 80% of the plasma concentration and the body as a whole, approximately 60%. The plasma contains more alcohol per unit volume than does whole blood because the former has a higher water content. Bone contains a small amount of water and takes up little alcohol. Fat tissue has a relatively poor blood supply and low water content and has only 10 to 20% of the alcohol concentration in blood. Obese individuals, therefore, have a higher blood alcohol concentration than normal individuals when both have the same intake per kilogram of body weight. The alcohol concentration in tissues, including the brain, parallels the blood level as the latter rises and falls. At the cephalic end, alcohol enters the cerebrospinal fluid in proportion to its higher water content. It diffuses into the lumbar region rather slowly, and a comparison of the alcohol concentrations in blood and lumbar spinal fluid shows a considerable diffusion time lag in the latter.

Small amounts of alcohol (2 to 4% of the total dose) are lost into the urine and into the respiratory air by diffusion. The alcohol in these excretions is in equilibrium with the blood alcohol passing through the kidneys and lungs; hence, a determination of the alcohol concentration in respiratory air or urine can be used to estimate blood concentrations for medicolegal purposes. No significant amount of alcohol is excreted as a glycuronide or sulfate conjugate, and there is no active excretion of alcohol itself by the kidney. The total amount of alcohol lost in the urine is in proportion to the average blood concentration during urine formation and the volume of urine excreted.

Approximately 2 liters of respiratory air contain as much alcohol as does 1 ml. of blood. The total amount of alcohol lost through the lungs can be increased somewhat by hyperventilation. Large doses of dinitrophenol have been used in experimental animals to induce a hyperventilation severe enough to increase the rate of elimination of alcohol from the body; however, this has no practical value in human intoxication. Fluctuations in the small amounts of alcohol excreted are relatively unimportant, and the only way that the bulk of the alcohol can be removed is by metabolic degradation.

Because of the many variables involved, it is dangerous to try to estimate the total amount of alcohol consumed from any given blood level. However, as a quick approximation, 1 ml. (800 mg.) of alcohol per kilogram of body weight taken over a period of one hour will give a maximum blood alcohol concentration in the neighborhood of 100 mg. per 100 ml. (0.1%) in 2 hours; this is equivalent to four or five ounces of whisky for a man weighing 70 kg. (154 lb.).[3] In New York state, a blood level of 0.15% alcohol is established by law as prima-facie evidence of intoxication. Some six to eight ounces of whisky is required by an average individual to reach this level, and one ounce per hour thereafter will sustain it at that level.

Rate.—Much of the controversial literature in the alcohol field has been concerned with problems related to variations in the rate of alcohol metabolism. Most of these divergent conclusions can be reconciled by recognizing that sluggish rates of alcohol metabolism can be increased to a so-called maximum in several ways, but that none of the procedures tested will cause this "maximum" to be exceeded. Positive effects can, therefore, be obtained when the initial rate of alcohol metabolism is sluggish, but no effect will be observed when the initial rate is already at the "maximum."

The rates of alcohol metabolism differ in various species, in animals of one species, and in the same animal at different times. The rate of alcohol metabolism in different humans has been estimated to vary between 100 and 200 mg. per kilogram of body weight per hour; the value of 200 mg. per kilogram per hour is equivalent to 840 ml. or about one-fifth of a gallon of 100 proof whisky (50% alcohol) per day for a man weighing 70 kg. The maximum upper limit is close to one quart per day (240 mg. per kilogram per hour).[4] A common estimate is that the human can metabolize about one ounce of whisky per hour (720 ml. per day). The blood alcohol concentration can decrease at a rate between 10 and 25 mg. per 100 ml. per hour, but the usual rate is between 15 and 20 mg. per 100 ml., and the upper limit appears to be 20 to 25 mg. per 100 ml. per hour. A single dose of 3 Gm. per kilogram (one pint of whisky for a man weighing 70 kg.) could be fatal, whereas the same amount taken over a period of time could be metabolized without difficulty.

The rate of alcohol metabolism has been reported to be constant and independent of dosage in a variety of species, but equally competent investigators have found a higher rate of metabolism when the blood alcohol levels are high. When an effect of dosage is observed, it is relatively small (e. g., 30% increase in rate when the blood alcohol concentration is 100 mg. per 100 ml. higher).[5] Since this difference is exceeded by the individual variability encountered at the same blood level, many conflicting conclusions have resulted. It seems reasonably clear that high blood levels tend to be accompanied by higher rates of alcohol metabolism (up to the maximum of 20 to 25 mg. per 100 ml. per hour decrease in blood alcohol). However, this maximum rate is achieved in some individuals at low blood alcohol concentrations, and no effect of increased dosage can then be observed. Estimates of the maximum rate of utilization are questionable when based on rates obtained at low blood levels.

From a theoretical point of view, a higher rate of metabolism at a higher blood level is incompatible with a linear disappearance curve and would be expected to give an exponential curve. If the curve is linear and is also affected by concentration, then the higher blood alcohol level must trigger off a high rate of metabolism that is sustained at this high rate throughout its disappearance. This phenomenon cannot be due to a direct effect of the higher substrate concentration on the alcohol dehydrogenase reaction but has been attributed to a secondary (perhaps hormonal) influence of high blood alcohol levels in speeding up the concomitant carbohydrate metabolism.[1a] This results in an increased amount of pyruvate that can enter into a coupled oxidation-reduction reaction with the alcohol.[6] In this coupled reaction, the pyruvate is reduced to lactate, and the alcohol is oxidized to acetaldehyde at a faster rate than would otherwise take place.

Factors Influencing Rate.—The effect of food in decreasing the intoxicating effects of alcohol is a common observation. Proteins effectively increase the rate of alcohol metabolism. This also has been observed with two individual amino acids, glycine and alanine. Fat or carbohydrate administration is without significant effect, although a previous high carbohydrate diet predisposes a high rate, and a previous high-fat diet predisposes a low rate of alcohol metabolism. In fasting, the rate remains high during the first few days while the carbohydrate reserves are consumed. The rate falls appreciably while the fat reserves are being utilized but increases again as the proteins are used. Feeding a low-protein diet reduces the rate by depleting the liver enzymes responsible for alcohol metabolism.[7]

The rate of alcohol metabolism is quite insensitive to the over-all metabolic needs of the organisms. Hyperthyroidism has no effect on alcohol metabolism. Exposure to external cold or muscular exercise sufficient to double the metabolic rate also has no effect on the rate of alcohol metabolism. Reducing the body temperature slows all metabolic reactions, and in cold-blooded animals the rate of alcohol metabolism follows the usual relationship for chemical reactions by being doubled for each rise in temperature of 10 degrees.

Three related substances, insulin, pyruvate, and fructose, have been reported by a variety of investigators to increase the rate of alcohol metabolism in animals and humans. This has been a highly controversial area, since about an equal number of investigators have obtained negative results. Most of the discrepancies can be reconciled with the following interpretation. 1. Glucose or insulin alone may increase the rate of alcohol metabolism in the dog or human, but the two together are more certain to increase the rate. 2. None of these agents appears to have any effect when the existing rate of alcohol metabolism is already high (a decrease in blood alcohol of 20 to 25 mg. per 100 ml. per hour), but all three will stimulate an initially sluggish rate (10 mg. per 100 ml. per hour) and increase it to the rate of 20 to 25 mg. per 100 ml. per hour. This relationship was described for the insulin effect by Widmark[8] over 20 years ago, and a similar relationship has been observed for the pyruvate effect.[1a] The rate of 20 to 25 mg. per 100 ml. per hour decrease in blood alcohol appears to be the maximum that can be achieved in these species, even with a brisk concomitant carbohydrate metabolism; lower rates of alcohol metabolism can be increased by stimulating carbohydrate breakdown.

The effect of insulin, insulin plus glucose, or fructose alone, can be attributed to an increase in carbohydrate metabolites such as pyruvate. Insulin is not required for fructose metabolism, and the administration of fructose alone increases blood pyruvate more than glucose does; this increase is suppressed when alcohol is also being metabolized. Glucose will increase blood pyruvate in the normal person but not in the diabetic unless insulin is also administered. Insulin undoubtedly increases the breakdown of glucose to pyruvate, and the effect of all of these agents on alcohol metabolism appears to have pyruvate or other carbohydrate intermediates as the common denominator. The increased rate of alcohol metabolism, resulting from the coupled oxidation-reduction reaction between pyruvate and alcohol, is accompanied by a mild metabolic acidosis in the human from the accumulated lactic acid.[9]

Alcohol and Carbohydrate Metabolism

The effect of alcohol on the blood sugar level appears to be the resultant of two opposing effects: (1) a stimulation of carbohydrate metabolism, which tends to decrease the blood sugar, and (2) a glycogenolysis, which tends to increase blood sugar at the expense of liver glycogen. In the normal person, the resultant is only a minor fluctuation in blood sugar; however, in the diabetic or others with depleted liver glycogen, alcohol administration decreases the blood sugar. Alcohol suppresses epinephrine or alimentary hyperglycemia and decreases the amount of liver glycogen formed from glucose. Alcohol itself is not converted to liver glycogen. Conversely, a high level of blood sugar does not have much effect on the rate of alcohol metabolism but will protect animals from the lethal effects of alcohol. A lethal blood alcohol concentration of 0.8% at a blood sugar level of 70 mg. per 100 ml. becomes 1.2% at a level of 200 mg. per 100 ml. of blood sugar.[10]

Diabetes.—In view of the previously noted relationship between alcohol and carbohydrate metabolism, the rate of alcohol metabolism in the untreated diabetic would be expected to be slowed. This has been demonstrated adequately in depancreatized animals. It is probably also true in human diabetics, but the variability encountered in the severity of the disease, the differences in insulin treatment, or insulin withdrawal before testing have led to inconsistent results.

The effect of alcohol in the diet of the diabetic has not been studied adequately. It seems clear that alcohol neither has a major antiketogenic effect in fasting or in diabetes nor is any major portion of the alcohol excreted as extra ketone bodies. The long-range effects of alcohol ingestion by the diabetic, particularly the stimulation of the adrenal cortex and the tendency toward fatty livers, are unknown.

Habituation and Tolerance

A tolerance to alcohol develops after its continued use, but it is lost after a number of months of abstinence. During the tolerance phase, larger doses of alcohol are required to produce the same pharmacological effect. Habituation to alcohol has no effect on the entry of alcohol into the central nervous system, the concentration of liver alcohol dehydrogenase, or the excretion of alcohol. The absorption of alcohol from the gastrointestinal tract is either unchanged or slightly more rapid after habituation, but it is clearly not delayed. Occasional data have been reported which indicate a higher rate of alcohol metabolism after habituation, but this is not found to be consistent in either animals or humans. It is generally agreed that habituation has no significant effect on the rate of alcohol metabolism. In the human alcoholic, tolerance to alcohol is first increased, but after long-continued use it returns to normal or subnormal levels. No correlation has yet been made between this change in tolerance and the extent of liver damage or between the rate of alcohol metabolism in the chronic alcoholic and the extent of liver damage.

It is quite clear that the phenomenon of tolerance cannot be attributed to a faster removal of alcohol from the system. At the same level of blood alcohol, the intoxicating effects are greater when the blood level is rising than when it is falling, and the electroencephalographic changes are also greater at any given blood level when it is rising.[11] Habituated animals and humans sober up faster, even though the level of blood alcohol falls at a normal rate. The phenomenon of tolerance is an adaptation of the central nervous system to alcohol rather than an alteration in the metabolism of alcohol. It is, therefore, theoretically possible to alleviate the intoxication symptoms without altering the metabolism of the alcohol. Such beneficial results have been reported from the use of insulin or the breathing of pure oxygen or a mixture of 90% oxygen and 10% carbon dioxide. The electroencephalographic changes that result from the consumption of alcohol are similar to those observed in anoxia, which enhances the intoxicating effects of alcohol. The caffeine in a cup of coffee may or may not alleviate the intoxication symptoms, but it has no effect on alcohol metabolism.[12]

Most unicellular organisms can tolerate an alcohol concentration of 2%, whereas yeasts can ferment sugar to an alcohol concentration of approximately 14%. The lethal blood level for many animals is in the range of 0.8 to 1.0%, but acute alcoholic deaths in humans sometimes occur at blood levels of 0.4 to 0.6%. Although the human is probably more sensitive to alcohol, these comparative figures cannot be accepted at face value because most acute alcoholic deaths in humans occur in physically debilitated individuals and often from causes other than the alcohol per se. Acute alcoholic death results from respiratory failure; however, if artificial respiration is used to maintain the animal, the blood alcohol level can be increased to 1.2 to 1.3% before cardiac failure ensues. Presumably artificial respiration would have a similar protective effect in the severely intoxicated human. The addition of glutamine to the growth medium of the bacterium Streptococcus faecalis inhibits the toxic effects of alcohol. How glutamine exerts this effect and whether a similar response could be obtained in mammals are still unknown.

Site and Pathway of Metabolism

Both the liver and kidney are rich sources of alcohol dehydrogenase, and both organs are capable of oxidizing alcohol to carbon dioxide at a brisk rate. In the intact animal, the liver is the major organ involved in both alcohol and acetaldehyde metabolism, whereas the kidney plays a minor role.[13] Hepatectomy or liver damage decreases the rate of alcohol metabolism significantly, but kidney damage has no effect. The rate of disappearance of alcohol from the blood can be correlated with the amount of active liver tissue present in the animal.

An eviscerated preparation metabolizes alcohol at less than 10% of the normal rate. Hence, the heart, lung, brain, muscles, and skin contribute very little to the metabolism of alcohol in the intact animal. On the basis of perfusion studies and the conversion of isotopic alcohol to carbon dioxide, the heart and lung can utilize alcohol slightly. Pigeon breast muscle utilizes alcohol, but mammalian skeletal muscle cannot metabolize alcohol. The brain has no significant alcohol-oxidizing ability. Isotopic alcohol is not converted to carbon dioxide by brain tissue in vitro, and there is no indication from in vivo studies that isotopic alcohol is metabolized by brain tissue.[14] Ordinary intoxicating levels of blood alcohol do not have any effect on the oxygen consumption or glucose utilization by the brain.

A variety of studies have indicated that alcohol is oxidized to acetaldehyde as the first step in its metabolism. Only those tissues containing alcohol dehydrogenase metabolize alcohol at a significant rate. Although catalase can oxidize alcohol in vitro under certain conditions, it is not responsible for alcohol oxidation in vivo. Blood acetaldehyde increases after alcohol administration in most species, including the human, but not appreciably in the dog. The increase in blood acetaldehyde is exaggerated by pretreatment with disulfiram (Antabuse). Alcohol dehydrogenase is a zinc enzyme that requires diphosphopyridine nucleotide as a cofactor and the cytochrome chain for complete reaction with oxygen. On the basis of the alcohol-acetaldehyde equilibrium constant, only a very small portion of the alcohol can be oxidized to acetaldehyde in vitro before the reaction stops. The reaction continues in vivo because the acetaldehyde is removed by further metabolism. The oxidation of alcohol to acetaldehyde is the slowest reaction in the chain of metabolic reactions and is, therefore, the one which must be accelerated in order to increase the rate of alcohol metabolism.

The fate of the acetaldehyde is still uncertain. Liver contains several enzymes that are capable of oxidizing acetaldehyde to acetic acid, but some of them are not involved in acetaldehyde metabolism.[15] Acetic acid cannot be detected in the intact animal's metabolism of alcohol. In vivo studies with isotopic alcohol have indicated that free acetic acid is probably not an intermediate. Acetyl coenzyme A (CoA) is probably formed from alcohol, since labeled alcohol gives rise to a labeled acetyl group in acetylated sulfanilamide. The major acetylating agent is presumably acetyl CoA. Acetaldehyde appears to be converted to acetyl CoA without first being oxidized to free acetic acid. The acetyl group of acetyl CoA could then be expected to be completely oxidized to carbon dioxide and water in the citric acid cycle. High concentrations of citrate have been found in rat kidney after alcohol administration.

Nutritional Value of Alcohol

Alcohol is a high-calorie food and yields about 7 calories per gram, as compared with 9 calories per gram for fat and 4 calories per gram for carbohydrate or protein. One ounce (30 ml.) of 100 proof whisky contains 15 ml. or 12 Gm. of alcohol, which contributes 84 calories. Three ounces of whisky is equivalent to one ounce of fat or oil from a caloric standpoint, and, because of its water solubility, alcohol has some possible utility in parenteral nutrition. It can furnish a large proportion of the daily caloric needs. Chronic alcoholics consuming a fifth of whisky per day obtain 2,240 calories from the alcohol; this represents over 75% of the average daily total intake of 2,500 to 3,000 calories. All of the distilled beverages supply calories but represent a diet grossly deficient in vitamins, minerals, and proteins. Beer and wine contain some protein, as well as a few minerals and vitamins, but their main nutritional contribution is calories. Twelve ounces of 4% beer or 4 ounces of wine containing 12% alcohol supply 81 calories.[16]

When the calories derived from alcohol are a small percentage of the total, the alcohol appears to contribute to the economy of the organism in about the same way as fat or carbohydrate; it spares protein degradation for energy and supports growth. However, when the calories derived from alcohol represent a major portion of the total intake, the alcohol is not as good a source of calories as either carbohydrate or fat; it then fails to support growth or weight restoration as well as an isocaloric quantity of fat or carbohydrate. It is possible that the calories in alcohol are not utilized in the body as well as the calories in carbohydrate or fat at all dosages but that the differences at low dosages are too small to detect. It is also possible that large doses of alcohol are wasteful because they dissipate body heat through a dilatation of the skin vessels. At the present time it is not clear whether alcohol can be utilized for muscle work. The alcohol itself cannot be oxidized by muscle, but intermediate metabolites might be utilized.

Alcohol neither changes the basal metabolic rate nor exerts any specific dynamic action. The theoretical respiratory quotient (CO_2/O_2) for the combustion of alcohol is 0.667. When an animal has a high respiratory quotient from the burning of carbohydrate, the administration of alcohol lowers it. This decrease in the respiratory quotient is accompanied by a slight increase in total oxygen consumption in order to maintain the same caloric turnover (120 calories per mole of oxygen for the combustion of glucose and 107 calories per mole of oxygen for alcohol.)[17]

Nutritional Complications

The high-alcohol diet consumed by many chronic alcoholics is nutritionally inadequate in many respects. Three deficiency syndromes are particularly common in alcoholics: (1) polyneuropathy resulting from thiamine deficiency, (2) pellagra resulting from niacin deficiency, and (3) fatty liver (and eventually cirrhosis) resulting from a low-protein, low-lipotropic intake. Wernicke's syndrome and Korsakoff's psychosis are often associated together in alcoholics and are thought to result from chronic nutritional deficiencies. Treatment with thiamine corrects some of the symptoms of the former but not the latter. Alcoholic polyneuropathy and pellagra were once thought to be due to a direct toxic effect of the alcohol but are now recognized as vitamin deficiencies resulting simply from an inadequate intake. These deficiencies can be corrected by the administration of appropriate vitamins, in spite of a continued high intake of alcohol. The amount of thiamine required in a diet is increased by a high-carbohydrate intake and decreased by a high-fat intake. Alcohol acts like fat in sparing thiamine; therefore, the thiamine deficiency in alcoholics cannot be attributed to an increased requirement.[18]

It should be emphasized that animals, including the human, eat in relation to their appetite, and the appetite is normally geared to their caloric needs. When his appetite has been satisfied, the animal stops eating, even though the intake of vitamins, minerals, and proteins is still inadequate. The dietary essentials must be present in the amount of food required to fulfill the caloric needs, or such essentials will not be obtained. Alcohol is not simply added to the diet that would otherwise be consumed in its absence, but instead it is substituted for some of the food. The more calories consumed as alcohol, the less food will be eaten. This substitution, resulting in decreased food consumption, is sometimes ignored experimentally when the alcohol is added to the drinking water or given separately from the food. An adequate diet can become inadequate in essential nutrients by adding alcohol to the total diet rather than substituting it for some of the carbohydrate or fat.

Fatty liver and cirrhosis are the characteristic features of chronic consumption of alcohol by animals or humans. With or without alcohol these changes are characteristic of a low-protein, choline-deficient diet and can be prevented or, in the case of fatty liver, be reversed by administration of choline or methionine or by a high-protein diet. It has not been established that small doses of alcohol have a greater effect in producing fatty livers than an isocaloric quantity of pure carbohydrate, but in many experiments the presence of alcohol appears to produce an earlier and more intense fatty change in the liver. It precipitates a more severe choline deficiency, as manifested by hemorrhagic degeneration in the kidney of the young rat.[19]

Large doses of alcohol exert a more specific effect in producing fatty livers than simply supplying calories, and this effect is mediated, at least in part, through the pituitary and the adrenal cortex. The rapid accumulation of liver lipids (11 to 15 hours) after alcohol has been consumed does not take place in an adrenalectomized or hypophysectomized animal, but the effect is restored by cortisone.[20] The fat deposition in the liver is prevented by fasting. No major portion of the alcohol itself accumulates as fat.

There is considerable evidence that relatively large doses of alcohol stimulate the adrenal cortex. Alcohol decreases adrenal cholesterol and ascorbic acid and causes involution of the thymus. As determined by the thymus maintenance dose, the adrenal cortical activity is increased markedly by alcohol. The adrenal hypertrophies with a continuing intake of alcohol, and the plasma 17-hydroxycorticosteroids are increased by a disulfiram-alcohol reaction.

Alcohol causes a release of vitamin A from the liver in various species, with a resulting increase in plasma concentration and a depletion of liver stores. Apparently no deficiency of vitamin A results from this effect, but rats on a deficient diet gain less weight when alcohol is added to minimal doses of vitamin A.

Summary

Alcohol is a high-calorie food and drug; it requires no digestion and imposes no absorption problems. It is distributed throughout the body water, and there are no effective ways of removing it except by metabolic degradation in the liver. The latter process is relatively slow and constant and leads to a complete burning of essentially all the alcohol ingested. Its rate of removal is dependent to some extent on the concomitant carbohydrate metabolism, but it is relatively independent of other factors. Tolerance to alcohol is an adaptation of the central nervous system rather than an altered rate of metabolism of the alcohol. As a food, it is a highly purified diet that supplies only calories; it thereby precipitates several vitamin deficiencies, as well as a fatty liver, and eventually cirrhosis. In large amounts alcohol is not as good a food source of calories as pure carbohydrates or fat.

NERVOUS CONTROL OF HOLLOW VISCERA.—The concept that the sympathetic and parasympathetic components of the autonomic nervous system act antagonistically to control the activity of the automatic tissues has established applicability in a very few situations—one being the control of the heart rate, for example. The idea that this balance between sympathetic and parasympathetic influences is of wide importance is derived in part from the anatomic fact of the dual innervation of some organs and in part by reasoning from the effects of injecting substances known to be chemical mediators.

There are, however, objections to any formulation which depends upon dual, antagonistic extrinsic nervous influences to explain the regulation of most of the intrinsically rhythmic tissues. . . . The results of nerve-section experiments are inconsistent with the concept that the control of bladder and intestinal activity is through antagonistic effects of the sympathetic and parasympathetic nervous systems. The urinary bladder is not paralyzed but is rendered hyperactive by parasympathetic ("motor") denervation. Intestinal activity is augmented by sympathetic denervation, but this effect cannot be due to unopposed vagal influences, since vagal section does not alter the hyperactivity.

A more consistent explanation is derived by considering that sensory denervation removes the sympathetic inhibitory tone initiated by distention of the organ, that is, that activity is limited by the same stimulus that initiates it.—F. H. Meyers, M.D., A Critique of the Concept of Sympathetic-Parasympathetic Antagonism, *Journal of The American Geriatrics Society,* February, 1959.

A CENTURY OF DENTAL PROGRESS

THE approaching 100th anniversary of the founding of the American Dental Association signifies a century of achievement and progress in the fields of dental education, dental science, and professional responsibility. The 90,000 members of the American Dental Association are professional descendants of the small group of 26 dentists who convened at Niagara Falls on August 3, 1859, to establish the first permanent dental organization in the United States. In the hundred years that have followed, American dentistry has achieved a maturity that has given it world leadership.

It was in the United States that dentistry was first recognized as a separate, independent profession with its own formal program of dental education. However, at the turn of the century many dental schools were still unadorned commercial enterprises, which gradual reforms, instituted by organized dentistry, forced out of existence. The accrediting agency of the dental profession has been the American Dental Association's Council on Dental Education. Through a well-conceived program of inspection and accreditation this body has exercised a pronounced impact on dentistry and dental education throughout the world. There are now 42 dental schools in the United States, all associated with universities. Postgraduate training has been encouraged by the Council on Dental Education. Last year some 22,000 graduate dentists enrolled in continuation courses, special clinics, and hospital teaching programs. Dental services can now be obtained in about one-third of the nation's hospitals.

A significant influence on the progress of dentistry in the 20th century has been dental research. With enhanced knowledge from scientific research have come advances in restorative dentistry, the discovery of new filling materials, new methods for the treatment of dental cavities, the introduction of procaine for the elimination of pain, new techniques and materials for the treatment of patients requiring dentures, and emphasis on the conservation of the diseased tooth. Finally came the realization that the only genuine solution to the problem of dental disease lay in prevention. Among more recent attitudes is the attention directed to the relation between the rate of dental decay and the concentrated sugars consumed, the measurement of decay activity as determined by bacterial counts in the saliva, and the effect of a trace of fluorine in drinking water on the rate of dental decay.

Dental scientists are now using radioactive tracers, the electron microscope, and polarized light and transillumination in an effort to unlock the mystery of dental decay. Comprehensive investigations on dental problems are being conducted in schools and research centers throughout the United States.

In addition, the American Dental Association has been a factor in advancing dental health on a world-wide scale by its active support of the Fédération Dentaire Internationale and through it the World Health Organization.

Thus it is apparent that the American Dental Association has a long distinguished record of public service and it can face the future with reasonable expectancy of significant improvements in the nation's dental health. THE JOURNAL of the American Medical Association extends centennial birthday greetings and best wishes for a second century of dedication to the welfare of the American people.

NATIONAL HOSPITAL WEEK

The observance of National Hospital Week, May 10-16, provides an opportunity for the medical profession to aid the nation's hospitals in developing better understanding of their services to the American people. Emphasizing the theme "More Roads to Recovery," the program this year will endeavor to explain how improvements in hospital care are making recent advances in medical science meaningful to every patient. This is an especially appropriate time for tours of hospital facilities, talks to community groups, radio and television programs, and newspaper announcements. National Hospital Week offers a splendid opportunity for cooperation between physicians and hospitals in creating greater appreciation of the entire medical team.

ORGANIZATION SECTION

SCHOOL HEALTH SESSION TO PRECEDE ATLANTIC CITY MEETING

School health will be the subject of a meeting to be held at the Claridge Hotel, Atlantic City, at 7:30 p. m. on June 7. Interested physicians will find it convenient to combine attendance at the school health session with the A. M. A. meeting which officially opens the next day. The program, to feature "The Changing Role of the School Physician," "The Future of School Nursing," and "Trends in School Health Education," is open to school personnel as well as to the medical profession. The American School Health Association is sponsoring the meeting in cooperation with the A. M. A. Department of Health Education.

NEW LEAFLET ON A. M. A. SERVICES

It's your A. M. A., and it's here to serve you!

This is the message of a new leaflet entitled "Science and Service to Humanity" being distributed by the American Medical Association to physicians with their 1959 membership cards.

The leaflet explains the meaning and value of A. M. A. membership and points out that by virtue of his membership each physician becomes an investor in humanity.

Although the leaflet does not attempt to cover all services, it stresses that each member has at his finger tips the vast scientific, socioeconomic, public service, and informational resources of the Association. The leaflet stresses that many A. M. A. members fail to take advantage of membership benefits. It urges doctors to use their membership privileges for their own benefit and for that of their patients.

SPECIAL SESSION ON AGING

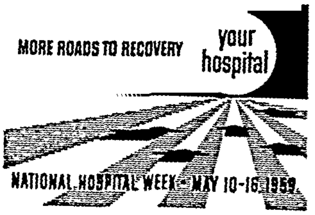
The Committee on Aging of the Council on Medical Service will present a special session on New Concepts in Aging during the annual convention of the American Medical Association in Atlantic City, June 8-12. This one-day session, to which all physicians are invited, will be held in Room C of the Convention Hall at 9 a. m. Wednesday, June 10. The meeting is being designed to present the practicing physician with a concentrated review of current thinking regarding health care of the aged and to provide him with concrete health recommendations which he can translate to his own older patients.

Keynoting the session will be a series of panels devoted to diseases among the aged, nutritional counseling, promoting physical fitness, and motivating the older person. Panel members will include such authorities as Drs. Leland S. McKittrick, Brookline, Mass.; Edward C. Reifenstein, New York; Irving S. Wright, New York; Walter E. Vest Jr., Denver; Frederick J. Stare, Boston; Norman Lee Barr, Bethesda, Md.; Ewald W. Busse, Durham, N. C.; and Howard P. Rome, Rochester, Minn.

These and 10 other experts in their fields will cover such points as (1) special treatment aspects of cardiovascular, neoplastic, and bone diseases among older persons, (2) effects of adequate nutrition on rehabilitation potential for older patients, (3) variables in prescribing a physical activity program for the older person, and (4) the effects of physical health, social adjustment, and psychological functioning on motivation in the older person.

Each panel presentation will be followed by a discussion period in which the primary interests of the audience will be explored and important ideas summarized. Dr. Edward L. Bortz of Philadelphia will close the session by summarizing the health recommendations brought out during the day in a "formula for full living" by the aging person.

Physicians planning to attend the session are invited to send questions or points they would like to see discussed to the Committee on Aging, A. M. A., 535 N. Dearborn St., Chicago 10. The areas of interest so indicated will be brought out as far as possible during the session. Queries should be received at A. M. A. headquarters not later than Wednesday, May 27.



COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The following study by the Council has been carried out during the past 30 months, as conceived and followed through by Glen R. Shepherd, M.D., Assistant Secretary of the Council. It was made possible only through the active cooperation and time of many institutions and organizations in supplying the information requested, and deep appreciation is expressed to them. It is presented in the expectation that the new information provided by the study will be of assistance in the future planning by the various groups involved to meet better the needs of physicians in continuing their education.

WALTER S. WIGGINS, M.D., *Secretary.*

A GEOGRAPHICALLY ORIENTED STUDY OF POSTGRADUATE COURSES AND ENROLLMENTS IN THE UNITED STATES FOR PHYSICIANS DURING THE YEAR 1956-1957

This article provides new information about the marked mobility of physicians enrolling in postgraduate courses, outlines a "threshold factor" in education, presents the distribution of subjects of courses, and points out the important role that medical centers have in attracting physician enrollments. The data and conclusions are based on a large representative sampling of 695 courses in which there were 20,432 enrollments. The study by the Council on Medical Education and Hospitals should be of interest and use to all those concerned with the planning of postgraduate courses for physicians, emphasizing as its data does the importance of regional and national conceptions in this field rather than confining the planning within each state, as has often occurred in the past, without regard to the educational opportunities elsewhere in the region and nation.

Introduction

For many years, the Council on Medical Education and Hospitals, in connection with its listing of postgraduate courses, has collected information on numbers of enrollments in the courses. With evidence of advancing interest in the continuation education of physicians as well as the apparent need for a more informed and concerted effort in this field, the Council intensified its studies in regard to the postgraduate courses that were to be offered in the year Sept. 1, 1956, to Aug. 31, 1957. Three new kinds of information secured that year from the sponsoring institutions and agencies pertained to (1) the characteristics of the courses, (2) courses that were cancelled rather than being actually offered, and (3) the geographical source of the physicians enrolling in the courses. An analysis of the characteristics of the courses was prepared and published in the annual report of the Council,[1] in 1957. The other information collected has been the subject of analysis and study during the intervening period, and it is the subject of this report.

It was initially expected, in planning this project, that physicians confined any travel they did for purposes of continuing their education to centers nearby, and that a geographically oriented study would reveal the regions involved. This would make it possible for all institutions and organizations in each region that wished to engage in some cooperative planning to do so with the knowledge that they were drawing their enrollments from the same places; i. e., that they were likely to be planning for the same physicians. However, study of the extensive data has revealed much other information than was originally anticipated. It is presented here with the expectation that it will be useful in future planning in this important phase of medical education.

Another project that is currently in progress is concerned with qualitative factors of postgraduate courses, with the expectation that if a suitable and reliable means of securing such information is developed, it will be possible to inform the profession only about those courses which merit their time and energy.

Perhaps the most basic premise on which the Council's activities in the field of postgraduate medical education are based is that high quality courses stimulate the participation of more physicians in further continuation education. It follows that the provision of a suitable number of effective courses is a sine qua non to other approaches designed to insure that physicians remain abreast of advances in medicine.

Presentation of Data

Methods of Study

The current study, as well as that presented two years ago, is based on information collected for and in relation to the postgraduate courses listed in The Journal.[2] The description of the educational activities listed in 1956-1957 was as follows: "Postgraduate medical education courses consist of planned activities for doctors of medicine intended to refresh physicians in various aspects of their basic medical education, to provide information on new developments in medicine, to acquire new skills, and to stimulate further educational efforts by the participants. Postgraduate courses for practicing physicians, for purposes of the listing, do not include clinical-pathological conferences, staff meetings, the conferences of an approved residency program, or the usual medical society meetings which are listed elsewhere in The Journal. Neither do they include courses accredited for specialty board certification or for credit toward advanced degrees."[3] The activities mentioned in the last sentence involve graduate medical education predominantly, not postgraduate, in the present frame of reference and terminology used by the Council.

The list of 1,280 courses was published in July, 1956.[2] Beginning with September, 1956, and continuing monthly, requests for enrollment information were sent to the sponsoring institutions and organizations about courses scheduled in that month. Follow-up requests were sent when information was not received. The median number of follow-up requests attempting to elicit the information was four, with a range from one to nine. The information requested in addition to the total number of course enrollments by M.D.'s in general or part-time specialty practice, in full-time specialty practice, and in residency training was the geographical source of each enrollment of an M.D. in practice, i. e., the city and state in which his practice office was located. Every attempt was made to secure as complete information as possible.

The thousands of items of information collected had to be dealt with by IBM punch-card methods. This was done by utilizing the grid numbers across the top of each map in a standard atlas as well as the letters down the side. The coordinates for each city in each state from which enrollments were reported were punched in the cards together with the number of enrollments and the city of the course involved. Since there were individual code numbers for each course, it was possible also to correlate the enrollment data in the geographical study with other characteristics of the courses.

Considering that this aspect of the study involved the geographical location of the courses as well as of the enrollments, the site of the courses was by city rather than by institution. This meant that for the 152 institutions and organizations sponsoring reported courses, only 73 cities were involved. This also required the designation of the "postgraduate center" (each of the 73 cities) as including certain satellite cities and suburbs in order to avoid an unwieldly and relatively unmeaningful large number of corporately separate though geographically related cities and towns. Thus, Seattle and Tacoma were considered as one center, as was San Francisco, Oakland, and nearby communities. The grouping will be presented in regard to the data obtained.

Because of the itinerant nature of circuit courses, they were excluded from the study. Home-study courses also were excluded. A total of 226 courses were cancelled for lack of sufficient physician enrollment.

After the machines had sorted and grouped the punched information in the several ways required, tabulations were printed by the machine. It was those tabulations that provided the data from which were obtained the tables as well as the maps.

In order to secure information about geographical relationships that would not be apparent otherwise, maps were drawn from the tabulated data, each map showing for a specific "center" the origin of its enrollments. In all, maps were prepared depicting the origin of the enrollments for 50 of the 73 postgraduate course centers. The remainder were not mapped for one of the following three reasons: 1. The number of enrollments was less than 20 and thus insufficient to provide significant information. 2. All of the enrollments came from the immediate vicinity of the city. 3. So many of the enrollments came from a widely scattered area throughout the United States that no regionalization was evident.

After the preparation of all the maps to the same scale of miles (2⅛ in. per 100 mi., with the master map for the United States thus being about 64 in. across), it was possible to prepare radii graduated in miles on transparent plastic to determine travel distances for the centers mapped. It was also possible to study the individual maps and compare them by superimposition to determine areas of overlap. In this way, significant relation or lack thereof between adjacent postgraduate course centers could be identified and the extent of the educational service area overlap determined.

The foregoing were the basic materials of the study from which were prepared rank order tables, correlations, and relationships, and from which the conclusions were drawn.

Comment

It should be made perfectly clear that the data collected, insofar as numbers of enrollments is concerned, does not reveal and should not be interpreted as showing the number of individual physicians enrolled in postgraduate courses. Enrollments cannot be equated with individuals because one physician may and often does enroll in more than one course. Thus, 10 enrollments may mean that one physician enrolled in 10 courses, or that two physicians each enrolled in 5 courses, or indeed any combination whose product equals the number of enrollments. The only valid relationship between numbers of individual physicians and numbers of enrollments is that there cannot be a higher number of individuals than is the total enrollment for the country. There can be and probably often are fewer individual physicians than is the number of enrollments or their sum.

Medical society	11	14
Government and other	15	13

Only if there were a national registry of the postgraduate course activities of all physicians in the United States would it be possible to secure information on the actual number of physicians enrolled in postgraduate courses in any given year. The data in this study about the mobility of physicians and their travel to places distant from their home state makes this conclusion inescapable.

This study is not presented as being totally inclusive, although it comprises a sufficiently large and representative sampling to enable significant conclusions to be drawn. The number of courses, as well as the number of enrollments, should always be understood in this report to refer only to the 695 courses regarding which geographical data on enrollments was reported to the Council (73% of the total of 951 courses reported for 1956-1957 excluding circuit and home study courses) and only to the 20,432 enrollments for which geographical source was reported (78% of the total enrollments of 26,231 reported in 1956-1957 exclusive of the 8,682 in circuit and home study courses). Therefore, when a state is cited as having no courses or as having a certain rank order, this may not be absolutely true, but it is the fact within the framework of this study, which can utilize only data that was supplied. Repeated requests were made to all sponsors of the courses listed for enrollment and geographical information. In 11 instances, seven such requests were made of each; in 2 instances, eight requests were made. In fact, there was a median of four requests made for information from sponsors who did not supply the information.

It is known that such lack of information distorted the picture in at least three centers, i. e., Minneapolis, Chicago, and San Francisco. In most other instances the data lacking was less important because of the presence of other institutions and organizations in the center cities which did supply sufficient adequate information or because the institutions or organizations which did not cooperate had relatively few enrollments or courses. It is

§ Because of lack of reporting by University of Minnesota, it appeared that only local enrollments occurred.

* Fewer than 20 enrolled.

also possible that of those reporting enrollments and geographical source, the data was incomplete. This is known to be true in one midwestern city, but if the complete information had been reported in that instance, it would have made an insignificant change in the rank order of enrollments, although it might have increased an already large average travel distance.

the courses in this geographical study are similarly distributed in terms of kind of course, sponsorship, location, educational methods, and who designed for, as compared with all courses reported in 1956-1957.[1] Table 1 presents this comparison. It reveals a remarkable similarity without significant differences, demonstrating that the 695 courses in the present study are a truly representative sampling

West Virginia	1,671	0	..	0	0	58	3.5	0	58	0.0	100.0
Wisconsin	3,920	1	1	1	1	143	3.6	11	132	7.7	92.3
Wyoming	256	0	..	0	0	37	14.4	0	37	0.0	100.0
District of Columbia	2,417	14	5	1	10	197	8.1	149	48	75.6	24.4
Totals		695	..	73	..	19,702	...	...	...	...	...

Despite the foregoing reservations regarding lack of perfection in the study, it should be emphasized that such a large percentage of the total enrollments and total number of courses is represented that it would seem reasonable to place considerable confidence in the validity of the over-all conclusions and hypotheses. However, this is the case only if

of all the postgraduate courses reported to the Council for the year 1956-1957. The disparities in table 1 are either not significant or would h pected. For instance, the necessary excl circuit and home study courses f study accounts for the diff "other" kinds of course preted as showing the number of individual physicians enrolled in postgraduate courses. Enrollments cannot be equated with individuals because one physician may and often does enroll in more than one course. Thus, 10 enrollments may mean that one physician enrolled in 10 courses, or that two physicians each enrolled in 5 courses, or indeed any combination whose product equals the number of enrollments. The only valid relationship between numbers of individual physicians and numbers of enrollments is that there cannot be a higher number of individuals than is the total enrollment for the country. There can be and probably often are fewer individual physicians than is the number of enrollments or their sum.

TABLE 1.—*Comparison of Characteristics of Courses in Geographical Study and of All Courses Reported in 1956-1957*

	% in Present Study	% of Total Reported
Kind of course

Postgraduate school	21	26
Hospital	11	12
Medical society	11	14
Government and other	15	13

Only if there were a national registry of the postgraduate course activities of all physicians in the United States would it be possible to secure information on the actual number of physicians enrolled in postgraduate courses in any given year. The data in this study about the mobility of physicians and their travel to places distant from their home state makes this conclusion inescapable.

This study is not presented as being totally inclusive, although it comprises a sufficiently large and representative sampling to enable significant conclusions to be drawn. The number of courses, as well as the number of enrollments, should always be understood in this report to refer only to the 695 courses regarding which geographical data on enrollments was reported to the Council (73% of the total of 951 courses reported for 1956-1957 excluding circuit and home study courses) and only to the 20,432 enrollments for which geographical source was reported (78% of the total enrollments of 26,231 reported in 1956-1957 exclusive of the 8,682 in circuit and home study courses). Therefore, when a state is cited as having no courses or as having a certain rank order, this may not be absolutely true, but it is the fact within the framework of this study, which can utilize only data that was supplied. Repeated requests were made to all sponsors of the courses listed for enrollment and geographical information. In 11 instances, seven such requests were made of each; in 2 instances, eight requests were made. In fact, there was a median of four requests made for information from sponsors who did not supply the information.

It is known that such lack of information distorted the picture in at least three centers, i. e., Minneapolis, Chicago, and San Francisco. In most other instances the data lacking was less important because of the presence of other institutions and organizations in the center cities which did supply sufficient adequate information or because the institutions or organizations which did not cooperate had relatively few enrollments or courses. It is

§ Because of lack of reporting by University of Minnesota, it appeared that only local enrollments occurred.
* Fewer than 20 enrolled.

also possible that of those reporting enrollments and geographical source, the data was incomplete. This is known to be true in one midwestern city, but if the complete information had been reported in that instance, it would have made an insignificant change in the rank order of enrollments, although it might have increased an already large average travel distance.

the courses in this geographical study are similarly distributed in terms of kind of course, sponsorship, location, educational methods, and who designed for, as compared with all courses reported in 1956-1957.[1] Table 1 presents this comparison. It reveals a remarkable similarity without significant differences, demonstrating that the 695 courses in the present study are a truly representative sampling of all the postgraduate courses reported to the Council for the year 1956-1957. The disparities in table 1 are either not significant or would be expected. For instance, the necessary exclusion of the circuit and home study courses from the present study accounts for the difference of 10% in the "other" kinds of courses.

TABLE 3.—*Enrollment, Courses, and Physician Populations by State Centers*

Totals		695	..	73	..	19,702	...	...	...	...	...

Despite the foregoing reservations regarding lack of perfection in the study, it should be emphasized that such a large percentage of the total enrollments and total number of courses is represented that it would seem reasonable to place considerable confidence in the validity of the over-all conclusions and hypotheses. However, this is the case only if [illegible] of the 73 "postgraduate [illegible] which geographical data were [illegible] that only 8 of the 73 [illegible] enrollments, while an additional [illegible] than 20 enrollments during the year. [illegible] having only local enrollments involved a total of 683 enrollments (table 4) (or 3% of the total enrollments) in 34 courses at 10 institutions. The eight centers having fewer than 20 enrollments in each had a total of 98 enrollments by physicians.

Of the 73 centers, maps were drawn for 50. In addition to the 15 centers having too few or entirely local enrollment as a reason for nonmapping, there were 6 centers whose enrollment was too widespread over the entire country or world for a map to reveal useful regionalization. These were Boston; Glen Cove and Roslyn, N. Y.; New York City; Oak Ridge, Tenn.; Salt Lake City; and St. Louis (whose hospital alumni day remained in the study). The course of one "center" (Southbridge, Mass.) actually took place in New York City and the enrollments

were so treated. However, the center number had already been assigned to Southbridge and so it is listed in table 2.

Table 3 presents the basic data from which the rank orders of tables 9 through 11 were obtained. Table 4 shows the geographical source of the 19,702 enrollments from states arranged by region (rather than alphabetically) along the left side to each side to each of the 72 centers similarly arranged by region along the top of the table. It should be noted *that table 4 presents the entire geographical data if only state boundaries are considered, although* the maps rather than table 4 are required to obtain the travel distance information. Physicians may cross a state line, such as from Kansas City, Mo., to Kansas City, Kans., without traveling more than a few blocks to a few miles.

tates of Origin, at Seventy-three Centers

from Canada and other countries were as follows: Boston, New York City, and Buffalo each had more than 100 such enrollments, and the District of Columbia and Miami each had more than 50. It is probable, on the basis of other information, that Philadelphia would be included in this group if the Graduate School of Medicine of the University of Pennsylvania had reported its out-of-country enrollments. There were a total of 730 enrollments from Canada and other countries in this study, or 3.5% of the total enrollments.

Table 5 presents the number of courses by state and category of subject matter as derived from the title of the course and any accompanying literature. The states were arrayed regionally in order that a clear picture of the geographical distribution of the subject matter could be obtained. Because the significance of the information in table 5 is more apparent in relation to the mobility of physicians and their demonstrated travel to courses over relatively large distances, discussion of the subject category information will be found later in this report.

Physician Mobility Marked

In table 6 is presented travel distance information obtained for enrollments to the 50 centers for which maps were prepared. The number of enrollments coming from considerable distances should be noted. It should be remarked that not all of the enrollments to any of the centers could be located on a map of the region, some having come from more distant places. Thus, in consulting this table, attention should be paid to the actual proportion of the total enrollments that were mapped to each center. The difference between that figure and 100% would represent travel from a greater distance. Although the maps were originally conceived to show regionalizations of postgraduate medical education, their more important uses in most instances were as a means of determining actual distances traveled by physicians enrolling in courses.

Table 7 presents the average travel distances in rank order from least to greatest. It, again, refers only to that proportion of the enrollment to each center that was mapped. The average travel distances were much larger than would have been anticipated.

By combining the information from the several states that compose a generally recognized region—such as California, Washington, and Oregon for the Pacific Region—table 8 was prepared. It was expected that this kind of grouping might show regional differences in willingness to travel, which to a degree it does. It serves better to emphasize the mobility of physicians throughout the country to postgraduate courses.

The evidence of physician travel over relatively large distances to enroll in postgraduate courses is one of the most important and least expected results of this study. It places the needs in this phase of education and the manner of meeting those needs in an entirely different dimension than if one assumes, as most have done in the past, that educational opportunities must be near to physicians if they are to take advantage of them. It also makes it evident that planning to meet the needs of physicians in their continuation education should not be

* Within the region.

confined to the locality or even the state or region in which the physicians practice, within certain limits as will be set forth when the "threshold factor" is considered. The educational opportunities in Ohio and Tennessee are important for Kentucky physicians, for instance, as are also the courses offered in much more distant places.

There is an interesting correlation between the presence of a medical school active in postgraduate courses and the distance from which enrollments in those courses came. With four exceptions, all 32 cities (or 87.5%) drawing enrollments from an average travel distance greater than 50 miles (table 7) have medical schools active in postgraduate courses. The four exceptions are in California, Texas, and Louisiana, where travel distances tend to be greater. However, only 8 (44%) of the 18 cities drawing from an average of 50 miles or less have medical schools. Those eight cities are in regions of the country where people are more reluctant to travel distances greater than 50 miles. The 10 cities having no medical schools and drawing enrollments with an average travel distance of 50 or fewer miles are in nine instances located in regions usually showing the greatest travel—Iowa, North Carolina, Texas, and California.

* Median distance.

Twenty-two (88%) of 25 cities that are above the median average distance traveled (68.5 miles) have one or more medical school active in postgraduate medical education. Only 14 cities (56%) of the 25 that are below the median average travel distance of enrollments have one or more medical schools active in postgraduate courses.

There seems to be a significant correlation between the courses offered by medical schools and the willingness of those in the profession to travel over considerable distances to enroll in those courses. One is tempted to infer from this a qualitative factor that is appealing to the profession.

The Threshold Factor

If comparison is made between tables 9 and 10 and between tables 9 and 11, an interesting correlation appears. Those states (28) having zero to three course subjects in the state are below the median (211) in originating postgraduate course enrollments to anywhere in the United States, with the following five exceptions: Maryland (which is close to Washington, D. C., and Philadelphia), Mississippi (which is only barely above the median enrollment), Missouri (which is immediately adjacent to Kansas on whose eastern border are given many more than the median number of course subjects), North Carolina (whose circuit courses are not counted in this study), and Virginia (which is also close to Baltimore, Philadelphia, and Washington, D. C.). Thus all of the exceptions are susceptible of explanation.

On the contrary, those states (21) having four or more course subjects in the state are above the median in originating postgraduate course enrollments throughout the nation, except the following: District of Columbia (where many of the courses are by and designed for the military doctor) and Louisiana. The explanation for the latter exception is not clear.

There is also a positive correlation between the number of course subjects offered in a region to the number of physician enrollments from that region to courses anywhere in the United States. The correlation that was pointed out for each state holds even truer for geographical regions.

To demonstrate the correlations just described, the graph in figure 3 was prepared. As the graph in figure 4 shows, it is not possible to correlate the number of course subjects in a state or region with enrollment in that state or region.

It thus appears that there may be in postgraduate medical education a factor which could appropriately be termed the "threshold factor," because its effect seems to be analogous to the galvanic threshold or rheobase found in physiology. It seems that if the "threshold dose" of postgraduate medical education in terms of subject matter variety of courses is offered in a state or geographical region, physicians are sufficiently stimulated or challenged to almost "explode outward" in enrolling in postgraduate courses throughout the country. The "threshold stimulus" appears to be about four subjects per year in a region or state. This would not be an impracticable basis for inducing more of the profession to participate in continuing education.

It is, however, a repeated experience in statistical analysis—in fact a part of the working philosophy of scientists—that positive or negative correlations, no matter in what degree, do not themselves establish cause and effect relationships. Thus, it is entirely possible that the "threshold factor" is an unwarranted assumption based on positive correlation rather than on a true cause-effect relationship. Certainly it would be unrealistic to suppose that mere number of course subjects, without regard to their quality of educational experience and out of context with the needs of the profession, would be likely to stimulate physician enrollments in other postgraduate courses. The fact that the qualitative factor is important in education requires no statistical support. In addition, however, it may be that a certain minimal availability of educational experiences stimulates further educational activities requiring more effort, such as travel.

Relation of Medical Schools to Courses

With only one exception, the 11 states having no courses also did not have four-year medical schools, although four states did have two-year schools of the basic medical sciences. Such schools are usually not as active in the continuation education of physicians as are the four-year medical schools.

Without exception, the upper 63% (31 out of 49) of states having the greatest physician enrollment in postgraduate courses somewhere in the country also had one or more four-year medical schools. However, 69 of the 81 four-year medical schools (85%) are located in those 31 states.

Without exception, those states having more than the median number of course subjects (five or more) had one or more four-year medical schools located in those states. In fact, 51 of the 81 four-year medical schools are located in those 24 states. Without exception also, all states having three or more courses in the state had one or more four-year medical schools.

That a medical school in the state does not assure an adequacy of postgraduate courses, though it appears to be an important factor, is shown by the fact that 9 of the 23 states having two or fewer courses had four-year medical schools, and four additional such states had two-year schools of the basic medical sciences. However, only one of the 11 states in which there were zero courses reported had a four-year medical school, although four of those states did have two-year schools of the basic medical sciences in 1956-1957.

Reference has already been made to the relationship of medical schools to the distances from which enrollments are drawn to the courses offered.

The significance of medical school sponsorship in attracting enrollments in postgraduate courses can also be noted by comparing enrollments in two cities in the same state, one with a medical school and one without. Since Iowa has already been mentioned, one might take the case of Iowa City with its medical school as compared to Des Moines not having a medical school. All of the courses in Iowa

City were sponsored by and took place at the medical school. In Des Moines, two courses were reported, one in an auditorium outside of a hospital and the other in a nonschool hospital, though both courses were sponsored by hospitals. Only 29% of the enrollments in Des Moines came from cities from which enrollments did not also go to Iowa City. Or, to put it the other way, 71% of the enrollments to Des Moines came from cities from which physicians also enrolled in the medical school courses in Iowa City. While Des Moines courses drew almost entirely from central Iowa, the courses in Iowa City drew enrollments from throughout the whole state (fig. 1) as well as from eastern Nebraska, Minnesota, Wisconsin, northern Missouri, and Illinois.

* Median number of enrollments.

Another striking comparison of the effect of courses in medical schools and medical centers as compared to courses having other sponsorship or location is the contrast between San Antonio and Houston, Texas, as well as between Temple and Houston, Texas. Considering only the enrollments from outside each city, 86% of the physician enrollments in courses at San Antonio came from cities from which physicians enrolled in courses in Houston. However, only 49% of the Houston enrollments came from cities from which physicians also enrolled in San Antonio courses. Further, while there were only two enrollments of physicians from Houston in San Antonio courses, there were 27 enrollments from San Antonio to Houston courses. There was an identical number of enrollments (162) in each city from physicians in the same city. While all of the Houston courses took place in medical school hospitals, the San Antonio courses were located in nonschool hospitals.

In contrasting Temple with Houston, it is noted that the two courses reported for Temple were located in nonschool hospitals. Only 14% came from places not also contributing enrollments to Houston.

It seems on the basis of information of this kind, together with the extreme mobility of physicians enrolling in postgraduate courses throughout the country, that reconsideration might well be given to the need or desirability of taking courses out to the profession in the form of circuit courses or remote operations by a medical school or postgraduate school. It is obviously more economical of limited faculty time in medical schools for the postgraduate courses to be located at the schools rather than in the hinterlands. It is also more frequently possible for such medical school and medical center courses to use active educational methods in addition to en masse lectures.

On the basis of the present study, it seems clear that physicians enrolling in postgraduate courses are willing to travel far greater distances than had previously been assumed, especially to courses sponsored by and located in medical schools. Therefore, there may not be nearly as great a need as has been thought previously for putting on what are often second-best courses "in the field" in order to reach physicians. It appears that of the practicing profession enrolling in postgraduate courses, many are willing to travel to medical schools over considerable distances even when nonschool courses are available nearby.

* Median number of courses.

The possibility that circuit and other remote courses serve a stimulating function in arousing the interest of physicians in traveling to schools for additional courses cannot be verified or denied on the basis of this study.

In order that the institutions and organizations who supplied enrollment information may have the full benefit of the information obtained, copies of the maps for their general region of the country will be mailed to each institution and organization active in postgraduate medical education. The publication of all 50 maps in this study is not feasible here.

Subjects of Courses

The 42 categories under which postgraduate courses were listed in 1956 are arrayed across the top of table 5, and the states are arranged regionally along the left, with the number of courses given in the appropriate column intersections. The table thus portrays at a glance the regions of the country generally lacking in many subject categories as well as those relatively completely supplied.

When this kind of tabulation was first contemplated, it was at an early stage of the study before it was realized how much and how far physicians traveled to enroll in postgraduate courses. It was thought that such a tabulation of course subject categories would assist in determining the needs in each state. The preceding data makes it abundantly clear that the table would be better utilized as indicating the subject matter needs in each general region of the country, comprising several states. For that reason, the states are arrayed in the table by regions geographically rather than alphabetically.

Canceled Courses Not Unique

The 226 courses that were canceled in the 1956-1957 year, usually because of lack of enrollment by physicians, were analyzed as to their gross characteristics. It was hoped that clues would emerge from those casualties which would be of assistance in planning in the future. Comparison of the gross characteristics of the 226 canceled courses with the characteristics of the courses actually given showed no significant differences in terms of sponsorship (medical school, nonschool hospital, medical society, etc.), educational methods, location (medical school, non-school hospital, hotel, etc.), kind of course (continuous versus intermittent), and those for whom the courses were designed (general practitioner or full time specialist or both). Thus, the gross characteristics of the courses did not appear to relate to whether or not they attracted sufficient physician attention to be actually given.

* Median number of subjects in states with courses.

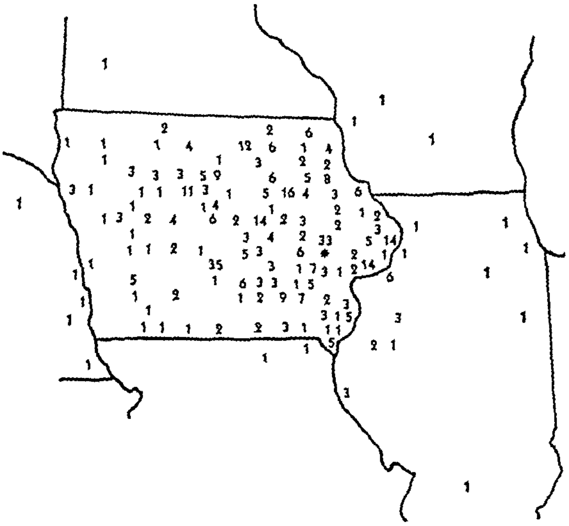

Fig. 1.—Map of enrollments in courses at Iowa City. Eleven courses were sponsored by one institution; 519 physicians registered, including 43 from Iowa City.

However, when the location of the canceled courses and their subject matter was compared with the location of courses actually given, the reason for cancelation became evident. In almost all cases, the courses canceled were in regions and on subjects in which other courses occurred. In fact, 191, or 84%, of the canceled courses were in the states ranking highest in the total number of courses given (New York, Massachusetts, Texas, Pennsylvania, and California). It was extremely rare for a course to be canceled if it was on a subject not already covered by other courses in the region. In those exceptional instances it is possible that the conflict was with dates scheduled, although the data in the study was not in such a form as to confirm or deny this assumption.

Table 8 reveals that at least one-fifth of the enrollments in each of the 10 regions were by physicians from a distance of 50 to 200 miles. Indeed, for the country as a whole, of the two-thirds of the enrollments that were mapped, almost one-third came from distances of 50 to 200 miles. In two of the regions, about one-half of the mapped enrollments came from 50 to 200 mile distances, and an additional five regions showed more than one-fourth of the enrollments from that distance. Even more impressive is the fact that in two of the regions, about half of the enrollments came from distances greater than 300 miles; one region had more than one-fourth its enrollments from distances greater than 300 miles, and an additional three regions had about one-fifth of the enrollments from such distances.

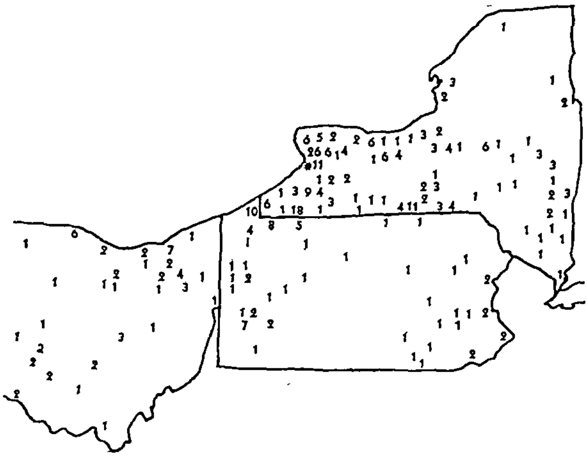

Fig. 2.—Map of enrollments in courses at Buffalo. Thirteen courses were sponsored by one institution; 572 physicians registered, including 55 from Buffalo.

The enrollments to New York City, Boston, and Washington, D. C. were not mapped, as they came from the entire United States and abroad. If the travel to those cities were included as related to postgraduate courses, then the mobility of physicians would be magnified rather than diminished. Without those figures in the travel distance study, it is likely that the tables present more realistic information of travel as it is directly related to continuation education. It is generally recognized that the above three metropolitan centers offer many attractions in addition to postgraduate courses. However, the courses at Denver that were in the study and in the mapping did not occur during the vacation season of June to September, when attractions other than education might be thought as possibly predominant.

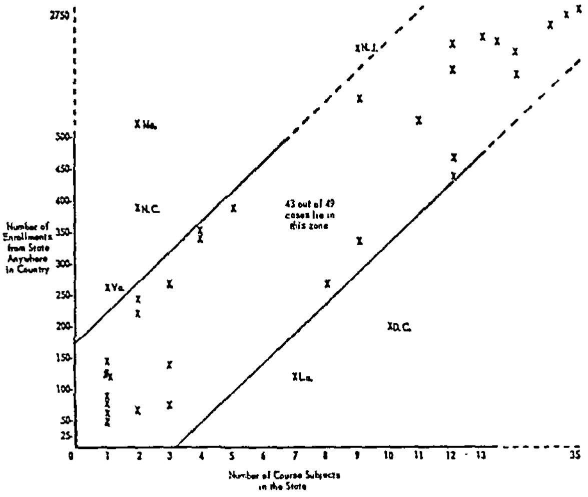

Fig. 3.—Graph showing correlation between number of postgraduate courses in specific region and enrollment of physicians from anywhere in the United States.

Careful study of table 4 also reveals the extreme mobility of large numbers of the enrollments in postgraduate courses. It might be thought that travel over comparatively large distances would involve only courses lasting a week or more. Such is not necessarily the case. The map in figure 1 shows enrollments for Iowa City. In that instance, only one institution is involved, the University of Iowa School of Medicine. Eleven courses were given, of which 10 were one to one and one-half day courses having an average and median duration of seven hours. The other was a four-day 26-hour course. All of the courses included open question periods, patient demonstrations, and audiovisual aids as well as lecture and panel discussion. All of the courses except one were designed for both physicians in general practice and in full-time specialty practice. The other was designed solely for physicians in general and part-time specialty practice.

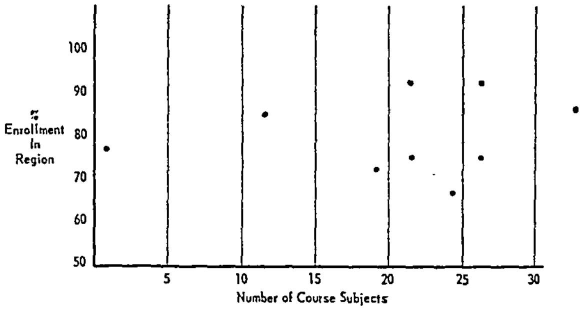

Fig. 4.—Graph showing lack of correlation between number of courses in specific region and enrollments in courses from same region.

Another example showing that the larger travel distances may involve brief rather than lengthy courses is the map (fig. 2) for Buffalo indicating enrollment in the courses offered by the University of Buffalo School of Medicine. Nine continuous courses were reported, each on a different subject area, with one being a one-day 7-hour course, seven being two-day 14-hour courses, and one a six-day 39-hour course. Six of the nine courses included ward rounds in the educational methods, and all used live clinics, patient demonstrations, seminars, open question periods, audiovisual aids, and panel discussions in addition to lectures. The University of Buffalo also scheduled six intermittent courses, three to six hours once a week for 4 to 20 weeks.

Thus, it seems that other factors and probably qualitative ones are more determinative in attracting enrollments from considerable distances than is prolonged duration of the course. This is also reasonable in terms of modern travel times by car, rail, and airplane.

Summary

The geographical origin of 20,432 enrollments in 695 courses given in the year Sept. 1, 1956 to Aug. 31, 1957, was tabulated, mapped, and correlated with geographical location of the courses, subject categories, and kinds of courses. The study comprises 78% of the enrollments and 73% of the courses reported to the Council that year, exclusive of circuit and home-study courses, which were excluded for obvious reasons. In both size of the sampling and characteristics of the courses in the study as compared to all of the courses reported that year, the present study consists of a representative sample from which highly significant conclusions may be drawn.

Physicians' mobility is high in relation to enrollment in postgraduate courses. For the country as a whole, almost one-third of the enrollments came from distances of 50 to 200 miles. Many enrollments were over distances in excess of 300 miles. There is some variation in willingness of physicians to travel that relates to the region from which they originate, with physicians in the eastern seaboard states traveling relatively smaller distances than physicians in the southern, midwestern, and western states. However, in this regard, it appears that the kind of course has greater importance in attracting enrollments from a distance than does the region of the country. It is definitely apparent that in all regions, physicians travel much farther to enroll in postgraduate courses than had previously been assumed. Their actual performance is thus different than is their attitude, as it was reported in the Vollan study.[4]

Medical school courses tend to attract physicians over greater distances than do other courses. There is also a direct relationship between the presence of four-year medical schools in states with the number of courses and course subjects as well as with the enrollments in courses.

There may be in postgraduate medical education a "threshold factor," in terms of number of course subjects in a state or region correlating positively to a high degree with the number of physician enrollments in courses throughout the country. Purely on the basis of such correlation, the threshold of educational stimulus appears to be about four course subjects in a state or region in a year. It is also possible that the correlation per se does not arise from a cause-effect relationship. Certainly the quality of the educational experience is an important factor that must be taken into consideration. Attending only to numbers of course subjects without regard to their educational quality would be a disservice to the profession. It may be that a certain minimum availability of educational experiences of high quality in a region might stimulate physicians to seek other educational activities requiring greater effort, such as travel to a distance.

There is no apparent relationship between the gross characteristics of courses and their likelihood of being canceled because of lack of physician interest. There is a relationship between location and subject categories of canceled courses with the courses given. Conflict of courses in terms of subject and location characterize the courses that were canceled in 1956-1957.

The data and conclusions of this study make apparent the importance of regional and national conceptions in the field of postgraduate courses. It would not be compatible with current reality to confine the planning within each state without regard to the educational opportunities elsewhere in the region and in the nation.

Miss Eileen O'Brien of the Council clerical staff aided in collecting the information secured.

Mr. Charles R. Flowers, Supervisor of the Machine Records Division of the American Medical Association, devised the approach whereby the actual location in each state from which enrollments originated could be punched into the machine cards; he also supervised the extensive machine records services required in this study.

COUNCIL ON MEDICAL SERVICE

FEDERAL MEDICINE AND THE PRIVATE PATIENT

Louis M. Orr, M.D., Orlando, Fla.

My remarks are based on the policy statements of the House of Delegates of the American Medical Association. We look to the Federal Medical Services Committee for implementation of these policies.

Veterans' medical care and the care of military dependents are specific examples of the federal government's participation in the practice of medicine. However, it would be well to consider here the larger picture, the general impact of these programs on American medicine as a whole, and especially on the private patient.

For the physicians and officials of the armed forces and the Veterans Administration, the area of responsibility is limited. Our area of responsibility is the whole nation, the whole American people, and we would fail in that responsibility if we allowed medical programs for one or two groups to expand unchecked at the expense of the rest of the nation.

We must achieve a balance between the medical care available to those persons who are legitimate responsibilities of the government and to the general public, who are our responsibility. Admittedly the veterans and the military comprise a large group, one out of every seven persons in the United States, but even so this group must not be allowed to become the "tail that wags the dog."

Dependent care in military hospitals began as a service to our men in uniform to supplement private medical care. Now private medical care has become officially secondary to that in the Army, the Navy, the Air Force, and Public Health Service hospitals.

The Veterans Administration hospitals, as you all know, were established to care for service-connected disabilities. Now we have reason to fear that this care is becoming subsidiary to a vast program of medical education and research involving an ever-increasing number of veterans with purely civilian disabilities.

The American physician is the last man on earth to oppose good care for our servicemen's wives, their children, and their parents and for our veterans. American medicine has long demonstrated its belief in the power of medical education and medical research to improve this nation's health. But is this the proper instrument to achieve these worthwhile goals? Is it in the best interests of our collective patient, the American people, to build up these federal research and educational and treatment programs at the expense of the civilian nonfederal medical system?

In July, Dr. Roth, chairman of this conference, and chairman of the Committee on Federal Medical Services of the American Medical Association, in testifying before the House Veterans Affairs Committee said: "Let me assure you that if this were a conflict between the best interests of the patient-public and the vested interests of the medical profession, the profession would inevitably yield to the public as it has on every occasion in the past." In other words, "the patient comes first." Even today when the physician is supported by a vast scientific armamentarium, the science of medicine is as much in the service of the patient as was the art of medicine when our diagnostic equipment was slighter. Is this wholly true in federal medicine?

I do not call into question the professional competence of physicians in the federal service. I know from personal experience that high caliber men are treating the patients in these hospitals. But does not the system under which these men work often present obstacles to giving the patient the best care possible?

For instance, the Medicare program was inaugurated to improve our servicemen's morale. Yet today a serviceman's wife who wishes to be with her husband during pregnancy must use the military facilities if it has the appropriate staff and adequate facilities are available. To choose her own obstetrician she must move away from her husband or pay for her own care.

It does not seem that any of these alternatives will help a soldier's morale very much. One of the most important things during pregnancy to the wife is a close physician-patient relationship. It means much to the expectant mother to know that she is going to be treated by her own personal physician, that she can consult him on any problem

---

President-elect, American Medical Association.

Read before the Conference on Federal Medical Services at the 12th Clinical Meeting of the American Medical Association, Minneapolis, Dec. 1, 1958.

that arises, that she can call him in the middle of the night in an emergency, real or imaginary, and obtain help.

Can a military hospital staff, by its very nature, provide that sort of personal care? I wonder if the current Medicare regulations do not make it more difficult to provide the best possible care for servicemen's dependents.

Medicare is comparatively new in comparison with the Veterans Administration system. I was chairman of the American Medical Association's Committee on Federal Medical Services before the present policy was established by the House of Delegates in 1953, and I retained that chairmanship until last June. I believe this partially qualifies me to speak as an "old hand" on the problems of veterans' medical care.

The Veterans Administration system as it presently exsists reminds me forcibly of the old adage, "You can't get something for nothing." We all know that—but Americans are incurable optimists and keep hoping that some day one of the big free offers will really come true. We go on collecting trading stamps, even though we know that the cost of the premium is added to the bill.

But does the veteran know what he pays for when he gets his "free" medical care? The man who is treated for service-connected illness or injury knows —and he has already given to this nation more than we can every repay. But how about the veteran who goes into a Veterans Administration facility for treatment of a civilian disability? Does he really think this care is as free as it seems to be?

Of course, he does not have to pay cash directly to the hospital or to the physicians who treat him, as he would in a private hospital—but he pays in other ways. He pays in time by staying in the hospital, away from home, job, friends, and family, a month longer on the average that he would in a private hospital. He pays in taxes for the constantly increasing cost of the Veterans Administration hospital system—more than 715 million dollars for hospital inpatient care alone this current year, not counting outpatient care and research and administrative expenses.

Here are a few choice figures from the midyear review of the 1959 federal budget:

Expenditures for compensation and pensions for veterans are expected to be 134 million dollars higher than in 1958, a total of $3,233,000,000.

The cost of veterans' medical care and hospital construction and modernization is expected to be 93 million dollars higher—a total cost of 911 million dollars, or almost a billion dollars.

More than half of the budget receipts of the federal government will be from individual income taxes. Twenty-two million veterans and their families comprise a sizable slice of the tax-paying population.

This is free care? Everyone here will contribute his share to the 36 billion dollars the Bureau of the Budget expects to collect from the income tax this year, and I think all of us have a legitimate reason to be concerned about where our money goes.

I think we may be especially concerned when even Representative Olin Teague, chairman of the House Veterans Affairs Committee, says, and I am quoting from the official record of the committee hearings of last July:

"In my opinion, when dollars are collected from taxpayers and come to Washington, and we return them to the local communities and States, they have shrunk in value, in almost every instance. I believe Dr. Stacy (of the Oklahoma County Medical Society) is right in saying that, in fact, most of the truly indigent veterans who have non-service-connected illnesses can be taken care of in existing State and private facilities without expense to the Federal government."

As a taxpayer, those words are of great concern to me. I do not see how they justify anything but a return of responsibility for veterans' indigent care to the state and the local communities—despite Congressman Teague's explanation that, as long as the federal hospitals are there, we should use them. That is the argument that started non-service-connected care more than 30 years ago when we had only 9,500 "extra" beds. Now we have more than 80,000 so-called extra beds. As a taxpayer I want to know where this is going to stop!

But I am not talking just as a taxpayer or as a veteran. I am talking as a physician, and about the effect of these programs on my chosen profession. Despite the vastness of the programs and the bills that are running up, I believe that the effect of these plans on American medicine is an even more urgent matter.

I have mentioned the loss in personal relationship between patient and physician in Medicare, which is, I am sorry to say, quite characteristic of most federal medicine. I have also said how and what the veteran is going to pay for his so-called free care, not just in taxes but in the time lost away from his family and from his job.

This loss of choice and these hidden payments would be enough reason for me to advise an individual patient to go to his own physician and his own hospital; in some cases I believe that Veterans Administration patients might even avoid hospitalization altogether through private care. But this is, after all, still a matter for individual decision. Under present laws, the patient can determine whether he should accept the government care, if a serviceman's dependent or a veteran "unable to pay."

But the community's loss from federal medicine is a matter which must directly concern all physicians. Congressman Teague has said tax dollars shrink when they go to Washington. We most certainly agree. They shrink in a number of ways, and one is that they buy a great deal less hospital care.

Comparing average lengths of stay, a bed in a nonfederal hospital can take care of five times as many patients as one in a Veterans Administration hospital. Comparing costs per case, a Veterans Administration hospital case costs about three times as much as a nonfederal hospital case.

These figures are taken from a detailed analysis of Veterans Administration hospital expenditures published this spring by the Committee on Federal Medical Services, their source being the Veterans Administration's own statistics. They make it difficult to understand how anyone can seriously urge continued Veterans Administration expansion especially while there are still areas in our nation inadequately supplied with hospital beds for the general population.

I cannot quote you similar figures for military hospitals, since the committee has not been able to find a breakdown of their operating costs which would allow a really accurate cost comparison with nonfederal institutions. However, it is obvious that these shrunken tax funds could be used more sensibly and profitably—in their unshrunken form—to provide more local health facilities for the entire population.

It is not just the waste of money or the competition for the tax dollar which is disturbing. We are also very seriously concerned about the competition for staff personnel. You have already heard this morning some discussion of the disproportionate share of internships and residencies in federal hospitals. This can have a number of interlocking results, all disturbing to the private physician. It can lead, and to a certain extent has already led, to a demand for greater variety in the federal case load, meaning more non-service-connected cases in the Veterans Administration and more dependents in the military hospitals. It can lead to greater federal control of our medical schools, not through a purposeful campaign but by default, as the private teaching hospitals drop internships and residencies, because of an inability to compete with the inducements offered by the government with our tax dollars. It can lead to a large group of physicians in this country whose total hospital experience during the educational process, from clinical clerkship to completion of residency training, has been under federal control.

These men will have little or no understanding of the private practice relationship between the individual physician and the individual patient, because their entire career will have been as salaried employees of the federal government.

It is not good for such a large segment of the American medical profession to be diverted from what has been in the past the main current of American medicine. It certainly is not good for those private hospitals which are unable to compete for interns and residents because they must meet their costs from income rather than from congressional appropriations. Some will be forced to reduce the services they can offer their patients. Some will be forced to employ full-time staff to replace the interns and residents they cannot obtain, with a consequent increase in the hospital bill. That bill is further raised because the federal government pays more than the prevailing wage for nurses in almost every section of the country.

As a result, the patient finds his hospital costs going up and his taxes going up, and fails to realize that the way in which those taxes are being spent is one of the very factors that pushes his bill higher. This would be almost ludicrous if it were not so nearly tragic in its possible consequences for our American medical system.

This question of hospital costs can be very irritating for a physician, since it is common practice to blame the medical profession for any increase in the cost of medical care, whether it comes in the form of hospital rates, prescription costs, or even insurance premiums. But I am even more concerned when this artificial forced increase and this artificial scarcity of professional personnel for nonfederal hospitals makes adequate hospital care more difficult for the civilian population to obtain.

John Donne's phrase about no man being an island "entire of itself" has possibly become overfamiliar in recent years, but like many familiar phrases, it is used so frequently because it is so true. It applies equally well in this area.

There is a definite interrelation between private and federal medicine. The legislators and administrators cannot make federal medicine an island, having no effect on medical practice in the rest of the United States.

We want the best possible federal medical program for those who are legitimate federal responsibilities—our servicemen, the veterans who suffered actual war damage, the American Indians who are still federal wards—but we must not allow the whole private practice of medicine to be vitiated by a vast overemphasis on military and veterans' hospitals.

It has been a pleasure to have this opportunity of telling you the reasons why these trends disturb me. I sincerely hope this conference will be a step toward the proper integration of federal medicine in the total American medical picture.

MEDICAL NEWS

ALABAMA

State Medical Education.—At the 98th annual session of The Medical Association of the State of Alabama the following officers were installed: president, Dr. William R. Carter, Repton; president-elect, Dr. Hugh E. Gray, Anniston; vice-president, Southeastern Division, Dr. James A. Brantley, Troy; state board of censors for five-year terms, Dr. Wilmot S. Littlejohn, Birmingham, succeeded himself and Dr. Grady O. Segrest, Mobile, succeeded himself.

CALIFORNIA

Annual Symposium in Long Beach.—The second annual symposium to be held in conjunction with the formal opening of the new 400-bed Memorial Hospital of Long Beach will have the theme "New Horizons in Medicine" and will be held Dec. 2 in the new hospital. For information, write Dr. George X. Trimble, Director of Medical Education, Seaside Memorial Hospital, 1401 Chestnut Ave., Long Beach 13, Calif.

Personal.—Dr. Andrew D. Hunt Jr., of Flemington, N. J., will head the outpatient clinics of the now-building, 22-million-dollar Palo Alto–Stanford Hospital Center. He will be director of ambulant services as well as associate professor of pediatrics at Stanford Medical School. Both appointments are effective April 1.——Dr. John H. Lawrence, professor and director of the Donner Laboratory of Medical Physics, University of California, Berkeley, was the guest of the Japanese Medical Congress in Tokyo during the first two weeks of April, where he gave two papers.

ILLINOIS

State Surgical Meeting.—The Illinois Surgical Society will conduct its annual clinical and scientific meeting in Chicago, May 18, at Cook County Hospital and the University Club. Dr. William Johnson, president of the society, is chairman of the surgical symposium. A total of 23 surgical clinics are planned. The evening of May 18, Dr. Willis J. Potts, Chicago, will present "Respiratory Emergencies and Complications in Pediatric Surgery." The Iowa Academy of Surgery will be guests at this meeting. Members of the medical profession are invited to all sessions. For information write the Illinois Surgical Society, Inc., Suite 1421, 122 S. Michigan Ave., Chicago 3.

Annual Meeting in Chicago.—The Illinois State Medical Society will hold its 119th annual meeting in the Hotel Sherman, Chicago, May 18-22. Scientific programs, presented on May 19-22, will consist of general assemblies, panels, and sectional meetings covering allergy, anesthesiology, cardiovascular disease, dermatology, EENT, medicine, obstetrics and gynecology, pathology, pediatrics, preventive medicine and public health, radiology, and surgery. The invited out-of-state speakers and their subjects will be:

Current Concepts on Anesthesia in the Aged, Dr. Henry K. Beecher, Boston.
Roentgen Diagnosis of Benign Gastric Ulcer, Dr. Harold O. Peterson, Minneapolis.
Some Comments on Treatment of Congestive Heart Failure, Dr. Robert O. Brandenberg, Rochester, Minn.
Indications for Surgery in the Middle Ear Deafness, Dr. Bruce Proctor, Detroit.
Sodium, Hypertension, and Primary Aldosteronism (Oration in Medicine), Dr. Jerome W. Conn, Ann Arbor, Mich.
Changing Concepts in the Use of Antibiotics in the Treatment of Surgical Infections (Oration in Surgery), Dr. Frank L. Meleney, Miami.
A Review of the 1958 Poliomyelitis Epidemic in Detroit, Dr. Joseph G. Molner, Detroit.
Vascular Complications in Pregnancy, Dr. Eugene A. Osius, Detroit.
Problems in Learning from Clinical Experiences, Dr. Eugene A. Stead, Durham, N. C.
A Critical Reevaluation of Nutritional Requirements in Growth and Development, Dr. Charles U. Lowe, Buffalo.
Recent Developments in the Etiology of Bronchial Asthma, Dr. Samuel C. Bukantz, Denver.
Cellular Diagnosis of Adenocarcinoma of the Female Genital Tract, Dr. James W. Reagan, Cleveland.
Systemic Therapy of Superficial Fungus Infections, Dr. Harvey Blank, Miami.

Dr. Raleigh C. Oldfield, of Oak Park, will give his presidential address at the Wednesday general assembly. The annual banquet will be hold on that night. For information, write Dr. Harold M. Camp, Secretary, Illinois State Medical Society, Monmouth, Ill.

Chicago

Dermatological Lecture.—The ninth Arthur William Stillians Lecture of the Metropolitan Dermatological Society of Chicago will be given at its annual meeting, May 13, by Dr. Milton E. Kurth, staff, Cook County Hospital and the University of Illinois, on plastic surgery in dermatology.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Annual Lecture.—The annual D. J. Davis Memorial Lecture on Medical History was given April 22 by Dr. Lloyd G. Stevenson, professor of the history of medicine, and dean of the Faculty of Medicine, McGill University, Montreal, P. Q., Canada, on "The Early Development of Internal Medicine in the United States."

Research Institute Elects Board Members.—At the annual meeting of the board of directors of the Hektoen Institute for Medical Research of Cook County Hospital March 26 the following were elected as members of the board: Mr. Arthur S. Bowes, Dr. Lowell T. Coggeshall, and Commissioner John J. Duffy.

Dr. Rostenberg Named Department Head.—Dr. Adolph Rostenberg Jr., professor and acting head of the department of dermatology, University of Illinois College of Medicine, was appointed professor and head of the department on April 14 by the board of trustees. The appointment, effective May 1, fills the vacancy created last September by the resignation of Dr. Marcus R. Caro. Dr. Rostenberg has been on the staff of the university since 1945, when he was appointed professor of dermatology.

Symposium on Steroid Therapy.—The Chicago Medical School will sponsor a symposium on Steroid Therapy to be held at the Drake Hotel, Chicago, May 15-16, with Dr. Edward F. Rosenberg as general chairman. Dr. John J. Sheinin, president, Chicago Medical School, will open the meeting with an address. Eleven papers are scheduled to be presented, and the program will conclude with a panel discussion on "Steroid Therapy in Medicine." There is no registration fee. For information, write Dr. Rosenberg at 109 N. Wabash Ave., Chicago 2.

MARYLAND

Resolution on Tetanus Immunization.—At a recent meeting, the Baltimore City Medical Society passed a resolution dealing with mass tetanus toxoid immunization, reading, in part, as follows:

> Whereas, there has been an increase in all age groups in the incidence of trauma and . . . the major portion of our population has not been actively immunized against tetanus, even though such protection has been afforded to all former armed service personnel and most children since 1940, and
>
> Whereas, the rate of temporary disability due to reactions to TETANUS ANTITOXIN administration is high despite all precautions, and permanent disability and even death do occur following the use of TETANUS ANTITOXIN, and
>
> Whereas, in . . . a sudden emergency . . . it would be well nigh impossible to adequately test large numbers of casualties for sensitivity to foreign protein, and
>
> Whereas, the above-mentioned complications . . . constitute a public health problem in this State, even though the incidence of tetanus as a disease is low; therefore be it
>
> Resolved, that the Baltimore City Medical Society go on record as favoring the accomplishment of universal, active immunization of the population, preferably by the administration of toxoid by the family physician, and further be it
>
> Resolved, that the Baltimore City Medical Society request the Baltimore City Health Department to help publicize the importance of this problem and to undertake the active immunization of the indigent, who are now cared for under the Medical Care program . . .

MASSACHUSETTS

Dr. Schall Honored.—Dr. LeRoy A. Schall, retiring Walter Augustus Le Compte Professor of Otology and professor of laryngology at Harvard Medical School, Boston, was the presiding officer at a two-day scientific session held recently in his honor by the Massachusetts Eye and Ear Infirmary, an affiliated part of the Massachusetts General Hospital. Dr. Schall had designated a number of his "outstanding students" at Harvard from the past 25 years to participate in the program. Out-of-town speakers included Dr. Julio Quevedo from Guatemala; Dr. John J. Shea from Memphis, Tenn.; Dr. Clair M. Kos, University of Iowa; Dr. Richard Thomas Barton, Los Angeles; Dr. J. H. Thomas Rambo, of New York City; and Dr. Norman Jesberg, Los Angeles.

Laboratory to Study Hearing Physiology.—A laboratory for studing the physiology of hearing has been established by the Massachusetts Eye and Ear Infirmary and the Massachusetts Institute of Technology, Boston. Doctors, neurophysiologists, and electrical engineers will work together in a program of research, treatment, and education. The new laboratory, which is sound-proof and vibration-proof, was built and equipped at a cost of $200,000 and will be operated under grants from the National Institutes of Health. Located at the infirmary, it is known as the Eaton–Peabody Laboratory of Auditory Physiology. Work in the laboratory is under the direction of Dr. LeRoy A. Schall, chief of otolaryngology for the infirmary and Le Compte Professor of Otology at the Harvard Medical School, and Walter A. Rosenblith, professor of communications biophysics at M. I. T. The research is under the direct supervision of Dr. John W. Irwin, director of the Microcirculatory Laboratory at the infirmary, and Nelson Yuan Sheng Kiang, neurophysiologist at M. I. T.'s Research Laboratory of Electronics.

MICHIGAN

Wayne Alumni Reunion.—Date of the 91st alumni reunion and clinic day for 2,500 graduates of Wayne State University College of Medicine, Detroit, has been set for Wednesday, May 13, according to Dr. Theodore I. Bergman, '32, president of the association. The one-day scientific meeting, climaxed by a reception and dinner dance, will be held at the Fort Shelby Hotel in Detroit.

Plan Mental Health Projects.—In recognition of the World Mental Health Day, April 7, the department of psychiatry, Wayne State University College of Medicine, Detroit, designated special research and development projects to be advanced in 1960 (World Mental Health Year) in harmony with the resolution of the World Federation Organization of Mental Health, a United Nations Agency. Dr. John M. Dorsey, chairman of the department, named the following projects selected by the staff for special emphasis: (1) the problem of child care and the psychological aspects of education as well as the psychiatric education of medical students; (2) the mental health of the college student; (3) problems of convalescence, vocational rehabilitation, and the psychological aspects of industrial medicine; (4) problems of migration and the migratory worker; (5) problems of addiction, including alcoholism and the industrial aspects of it; and (6) problems of depression and suicide, with special reference to the rescue fantasy.

NEW JERSEY

Spring Symposium on Diabetes.—The New Jersey Diabetes Association in cooperation with the New Jersey State Department of Health will present a spring symposium on "Neurovascular Complications of Diabetes Mellitus" at St. Peter's General Hospital, New Brunswick, May 13. The following papers are scheduled:

Trophic and Ulcerative Lesions of the Lower Extremities in Diabetes, Dr. Norman Rosenberg, New Brunswick.

Diabetic Triopathy-Retinopathy, Nephropathy and Neuropathy, Dr. Robert F. Bradley, Boston.

Diabetic Neuropathy Involving the Autonomic and Parasympathetic Nervous Systems, Dr. Charles Shuman, Philadelphia.

Central Nervous System Complications of Diabetes Mellitus, Dr. Sherman Gilpin, Philadelphia.

A panel discussion moderated by Dr. William Levison will conclude the meeting. For information, write Dr. Arthur Krosnick, State of New Jersey Department of Health, Trenton 7, N. J.

NEW YORK

Dr. Thomas to Come to Albany.—Dr. Wilbur A. Thomas, associate professor of pathology, Washington University School of Medicine, St. Louis, has been named professor of pathology and chairman of the department at Albany Medical College and pathologist-in-chief at Albany Hospital, effective July 1. He will succeed Dr. Arthur W. Wright, department chairman for 25 years. Dr. Wright, who reaches the administrative retirement age this year, will continue as professor of pathology. Dr. Thomas was named instructor in pathology at Washington University in 1953, was elected a diplomate of the American Board of Pathology in the following year, and became associate professor in 1957. From September, 1957, to March last year, Dr. Thomas served as visiting professor and acting head of the department of pathology at the University of Baghdad, under a Fulbright fellowship.

Annual Convention in Buffalo.—The 153rd annual convention of the Medical Society of the State of New York will be held May 9-15 at the Hotel Statler-Hilton, Buffalo. Section meetings will be held during the mornings with general sessions in the afternoons, including the following symposiums and panel discussions:

Hypnosis in Clinical Practice, moderated by Dr. Hyman S. Barahal, West Brentwood.

Management of Patients Requiring Operation, Dr. Irving Pallin, Brooklyn.

Advances in Pulmonary Diagnosis and Treatment, Dr. Arthur Q. Penta, Schenectady.

Surgery in Cardiovascular Disease: Indications and Results, Dr. Francis W. O'Donnell, Buffalo.

Present Status of Oral Hypoglycemic Agents, Dr. Grosvenor W. Bissell, Buffalo.

Prognosis in Surgically Treated Cancer, Dr. Harry W. Hale Jr., Buffalo.

Control of Infectious Hazards in Home and Hospital, Dr. Morris Greenberg, New York.

Role of the General Hospital in the Care of Special Medical Problems, Dr. William A. Kelly, Mount Vernon.

The A. Walter Suiter Lecture, "Recent Progress in Our Understanding of Bilirubin Metabolism and Jaundice," will be given by Dr. Irwin M. Arias, Bronx. The history of medicine section will hold a symposium open to the public on "History of Microscopy—1590 to the Present" the morning of May 15. Speaker at the May 11 reception will be Dr. Gunnar Gundersen, LaCrosse, Wis., President, American Medical Association. Exhibits and films are planned. For information write the Medical Society of the State of New York, 750 Third Avenue, New York 17.

New York City

South African Visitor.—Dr. John Fleming Block, Cape Town, a former Rhodes Scholar and medical research fellow at Harvard, presented a lecture on "Human Nutrition and its Growing Importance to Clinical and Investigational Medicine" at the Cornell Medical College, April 15, as part of the Squibb Centennial Lecture series.

Lay Teachers Take Orthopedic Training.—Forty-five New York City school teachers are "going to school" at the Hospital for Joint Diseases, 123rd Street and Madison Avenue, to learn how to detect bone and joint ailments among their pupils and how to handle handicapped youngsters in their classrooms. The course, on the graduate level, began Feb. 17 and ends June 2. It consists of a series of 15 hour-and-40-minute lectures, discussions, and film showings by physicians, social workers, rehabilitation counselors, school guidance counselors, visiting nurses, and educators. These are held every Tuesday at 3:45 p. m. at the hospital. Ailments to which children in the growth years are subject are demonstrated to the teachers by physicians on the hospital's staff. The course is sponsored jointly by the Board of Education's Bureau for the Education of the Physically Handicapped, Play Schools Association, and the Visiting Nurse Service. The purpose of the course is to facilitate the early detection of orthopedic ailments. It is being directed and coordinated by Dr. Barnard Kleiger, attending orthopedic surgeon at the Hospital for Joint Diseases.

OHIO

History of Medicine Meeting.—The Cleveland meeting of the American Association of the History of Medicine will be held May 21-23 and will deal with aspects of medical history, from vaccination to surgical pathology in the Renaissance. On May 22 a "Symposium on the Heart" will include Drs. Carl J. Wiggers, Victor A. McKusick, Harold Feil, and George H. A. Clowes, Jr. A round-table discussion commemorating the centennial of Charles Darwin's "Origin of Species" will be held May 23. The annual dinner will take place the evening of May 22. All meetings will be held at the Cleveland Medical Library, and interested persons are invited. Local Chairman is Dr. Bruno Gebhard, Cleveland Health Museum, 8911 Euclid Ave., Cleveland 6.

OREGON

Cancer Conference in Portland.—An Oregon Cancer Conference will be held July 16-17 in Portland under the joint sponsorship of the Oregon State Medical Society, the Oregon Division of the American Cancer Society, and the University of Oregon Medical School. The conference is planned as a special feature of the Oregon Centennial celebration. The guest speakers will include Dr. Arthur C. Allen, professor of pathology, and Dr. Ralph Jones Jr., professor of medicine, University of Miami School of Medicine, Coral Gables, Fla.; Dr. Gilbert H. Fletcher, Houston, Texas, radiologist, Tumor Institute of the M.D. Anderson Hospital; Dr. Leslie M. Smith, dermatologist, El Paso, Texas; Dr. Francis Bayard Carter, professor of obstetrics and gynecology, Duke University School of Medicine; Dr. Gilbert Dalldorf, Albany, N. Y., director, Medical and Scientific Research Department, National Foundation; and Dr. John E. Dunphy, Portland, professor of surgery, University of Oregon Medical School. Each guest speaker will participate in one or more panel discussions. The program is being developed under the direction of the Committee on Cancer, Oregon State Medical Society, with Dr. Martin A. Howard, Portland, chairman. All sessions will be held in the library auditorium at the University of Oregon Medical School. The banquet the evening of July 16 will be held at the Hotel Multnomah. For information and reservation forms, write Mr. Roscoe K. Miller, Executive Secretary, Oregon State Medical Society, 1115 S. W. Taylor St., Portland 5, Ore.

PENNSYLVANIA

Ophthalmology-Otolaryngology Meeting.—Governor David L. Lawrence of Pennsylvania will be the honor guest at the annual meeting of the Pennsylvania Academy of Ophthalmology and Otolaryngology at the Bedford Springs Hotel, Bedford, May 21-23, with Dr. Murray F. McCaslin, Pittsburgh, presiding. Sixteen speakers will hold scientific sessions and instructional courses in ophthalmology and twenty-four speakers will participate in scientific discussions and study clubs concerning problems and progress in otolaryngology. On Thursday, May 21, a special highlight of the meeting will be a symposium on medical economics. Following this, the otolaryngologists will discuss the otologist and the dispensing of hearing aids. Members of the Medical Society of the State of Pennsylvania and their wives are cordially invited. For information, write Dr. Benjamin F. Souders, 424 Walnut St., Reading, Pa.

RHODE ISLAND

Annual Meeting in Providence.—The Rhode Island Medical Society will hold its annual meeting May 12-13 in Providence. The Chapin Oration will be given by Dr. John R. Paul, New Haven, Conn., on "Chapin and Modern Epidemiology." The program includes the following papers:

The Value and Limitations of Liver Function Tests, Dr. Franklin M. Hanger, New York City.

The Rhode Island Women's State Cytology Program: Progress Report, Dr. Yo Seup Song, Providence.

Medical Aspects of Iatrogenic Disease, Dr. Anthony P. Caputi, Newport.

Viral Infections of the Respiratory Tract, Dr. Harry M. Rose, New York City.

Indications and Results of Inferior Vena Caval Ligation in the Treatment of Thromboembolic Disease, Dr. John B. Blalock, New Orleans.

Visual Problems in Roentgen Diagnosis, Dr. William J. Tuddenham, Philadelphia.

Bronchogenic Carcinoma: Predisposing Causes, Dr. Alton Ochsner, New Orleans.

A panel discussion on "Deafness" is planned for the morning of May 13. Dr. Francis B. Sargent will present the presidential address on "Our Allies, the Hospitals and Blue Plans; Assets or Liabilities?" The meeting will conclude with a dinner at which Dr. F. J. L. Blasingame, Executive Vice-President, A. M. A., will present "Reorganization of the American Medical Association." For information write the Rhode Island Medical Society, 106 Francis St., Providence 3.

TENNESSEE

Dr. Rogers Receives Pathology Award.—"For basic research on how tumors and cancers behave and grow," Dr. Stanfield Rogers, director of Memorial Research Center of the University of Tennessee, Knoxville, received the third annual award of the American Society for Experimental Pathology, April 15. The award, and a $1,000 honorarium contributed by Parke, Davis & Company, honors original research by pathologists under 40 years old. Dr. Rogers' experiments began in 1947 at the Rockefeller Institute for Medical Research, New York City, and were continued at Duke University, Durham, N. C.

UTAH

Surgical Meeting in Ogden.—On May 20-22, the Ogden Surgical Society will hold a meeting under the presidency of Dr. Noall Z. Tanner. The program includes a panel discussion on "Pancreatitis" and meetings of specialty groups. The following are listed as participants:

Drs. John H. Mulholland and Mather Cleveland, New York City; George S. Sharp, Pasadena, Calif.; Hamish W. McIntosh, Vancouver, B. C.; Rodney H. Maingot, London, England; Everett G. Grantham, Louisville, Ky.; Donald W. deCarle, San Francisco; James T. Priestley, Rochester, Minn.; J. Hartwell Harrison, Boston; Stewart G. Wolf, Oklahoma City; Clifford G. Grulee, Evanston, Ill.; Nathan J. Smith, Daniel G. Morton, and Howard P. House, Los Angeles; R. Adams Cowley, Baltimore; and Alton Ochsner, New Orleans.

Luncheon discussions and a ladies' luncheon are planned. For information write Dr. L. D. Nelson, Washington Terrace, Ogden, Utah.

VIRGINIA

David C. Wilson Lecture.—On May 14, Dr. William Malamud, president, American Psychiatric Association, and research director of the National Association for Mental Health, will present the first David C. Wilson Lecture in Psychiatry at the University of Virginia School of Medicine, Charlottesville. This is the first of a series of lectures established at the university in honor of Dr. Wilson, who was chairman of the department of neurology and psychiatry for 26 years and has been professor of neurology and psychiatry for 30 years. Upon his retirement as chairman in 1956, the David C. Wilson Society was established, and this lecture is sponsored by the society with assistance of a grant from the Mona Bronfman Sheckman Foundation.

Roanoke Hospital Wins Safety Award.—Roanoke Memorial Hospital, Roanoke, was announced as the "grand award winner" of the 1958 Hospital Safety Contest, co-sponsored by the American Hospital Association and the National Safety Council. The contest was judged on the basis of the lowest number of injuries among employees of individual hospitals in relation to the number of man-hours worked during the year-long contest. The 280 hospitals which completed the contest reported a total of 367,075,000 man-hours worked during 1958, with a total of 3,042 injuries incurred resulting in at least one day lost from work. The contest is designed to encourage the observance of safety practices among hospital employees. Roanoke Memorial Hospital, with 530 employees, operated 1,168,346 man-hours last year without a reportable injury to win the grand award.

WASHINGTON

Allergy Meeting in Richland.—The Washington State Allergy Society will hold its spring meeting May 16 at the Desert Inn Hotel, Richland. The following papers are scheduled:

Pollens of the Northwest and Their Control, Dr. James E. Stroh, Seattle, and Ted W. Galbraith, B.S., Pasco.
Meteorology and Aero-Allergens, Glenn R. Hilst, Ph.D., Richland.
The Removal of Aero-Allergens, Don Wisehart, B.S., Richland.
Atmospheric Physics and Factors Which Influence Allergic Individuals, Dr. Konrad J. K. Buettner, Seattle.
Air Ion Density and Its Relation to Allergic Conditions, Dr. A. G. Corrado, Richland, and J. C. Beckett, San Francisco, Calif.
Industrial Allergy, Dr. Sherman M. Williamson, Seattle.

At the noon luncheon Mr. Daggett W. Norwood, of Richland, will present "Miracle of the Atom." A business meeting will conclude the formal program. Dr. Stroh is president of the society and Dr. Herbert L. Cahn, Richland, is the secretary.

Cancer Symposium on Spokane.—On May 25-26 a Cancer Symposium will be held at the Davenport Hotel, Spokane, sponsored by the Spokane County Unit, American Cancer Society. The program will open with an address by Dr. Clarence Lyon, president, Spokane County Medical Society, followed by an address by Dr. Alton Ochsner, New Orleans, on "New and Practical Approaches to Chemotherapy of Cancer." Four panel discussions are planned with the following moderators:

How to Treat Primary Cancer of the Breast, Dr. G. Edward Schnug, Spokane.
The Spread of Cancer During Surgery and Chemotherapy in Cancer, Dr. John Sonneland, Spokane.
Recent Changes in Diagnosis and Treatment of Lung Cancer, Dr. Waverly Ellsworth, Spokane.
Colonic Polyps, Cancer and Treatment, Dr. Carl Schlicke, Spokane.

Two films are planned and breakfast, dinner, and luncheon programs are arranged. Participants include the following: Drs. Warren Cole, Chicago; L. Henry Garland, San Francisco; George Moore, Buffalo; W. Bradford Patterson, Boston; Jerome Urban, New York City; and David Wood, San Francisco. For information write Dr. John Sonneland, Doctors' Building, 104 W. Fifth Ave., Spokane 4, Washington, General Chairman.

GENERAL

Information Exchange for Ophthalmologic Research.—The National Committee for Research in Ophthalmology and Blindness, 406-C South Boulevard, Evanston, Ill., established a confidential information exchange for groups seeking scientists, physicians, or technical personnel interested in research in ophthalmology and blindness. Institutions or individuals interested may secure information from the committee office.

Certification in Child Psychiatry.—The American Board of Psychiatry and Neurology, Inc., announced that it is undertaking subspecialty certification in child psychiatry for those child psychiatrists meeting the required standards. Information may be obtained by writing Dr. David A. Boyd Jr., Secretary-Treasurer, American Board of Psychiatry and Neurology, Inc., 102-110 Second Ave., S. W., Rochester, Minn.

Grants for Blood Research.—The Hematology Research Foundation invites applications for grants-in-aid for hematologic research for a period of one year. Applications must be submitted no later than June 25 to Hematology Research Foundation, 64 W. Randolph St., Chicago 1. Nine copies of application are requested (application forms are available upon request). Awards will be announced by the medical advisory board, which will choose the applicants on the basis of the proposed research project.

Health Council Membership Increases.—The executive committee of the National Health Council reestablished the membership of the American Hospital Association in the council. The action followed a meeting of the board of trustees of the American Hospital Association in Chicago, when it was voted to have the association reaffiliate with the council. The move brought to 65 the membership of the council, which was established in 1921, and is composed of national organizations concerned with health improvement. Other recent additions to the membership of the council include the American Medical Association, and the American College of Preventive Medicine.

Request for Civil War Data.—Dr. Morgan B. Raiford, Ponce de Leon Infirmary, 679 Juniper St., N. E., Atlanta 8, Ga., announced that "1961 will be the centennial year of the formation of the medical services, both of the Confederate and Union Forces. The Atlanta Historical Society and the Civil War Round Table have been given funds to establish an exhibit on medical services of the Confederate Armies for the centennial period [and] to collect as much informative data regarding this era of medicine as possible . . ." Anyone having information, items of interest, or photographs (to lend) of interesting correspondence and medical equipment should write to Dr. Raiford at the above address.

Catholic Hospital Convention in St. Louis.—The 44th annual convention of the Catholic Hospital Association of the U. S. and Canada will be held at Kiel Auditorium, St. Louis, June 1-4, with "Management: A Sacred Trust" as the theme. Preconvention meetings will be held May 30-31. Speakers from the health and hospital fields and industry will be featured during the convention. Rev. John J. Flanagan, S.J., executive director of the association, said the entire program has been designed for all hospital personnel who have supervisory responsibilities. "It will develop basic general principles of management applicable to all departments in the hospital," he said. For information, write the Catholic Hospital Association, 1438 S. Grand Blvd., St. Louis 4.

New Journal on Research of Lipids.—The first issue of the *Journal of Lipid Research* will be that of September, 1959. Donald B. Zilversmit, Ph.D., is editor, and Drs. Joseph H. Bragdon and Jules Hirsch are associate editors. Corresponding editors include specialists from Canada, Sweden, France, Germany, England, Belgium, Israel, and Japan. The journal, a quarterly, will publish original articles dealing with the chemistry, biochemistry, enzymology, histochemistry, and physiology of the lipids and will contain review articles and a listing of new lipid methods published in other journals. Copies of "Instructions to Authors" may be obtained by writing to the editor at the Editorial Office, University of Tennessee, Memphis, Tenn. Subscription price is $6 per year.

Report on Longevity.—Average length of life of America's wage earners increased slightly in 1958 after showing a small decrease the preceding year, statisticians of the Metropolitan Life Insurance Company report. According to provisional mortality figures for 1958, the average length of life (expectation of life at birth) for the Metropolitan's millions of industrial policyholders was 70.2 years, an increase of 0.2 years over the figure for 1957. The average length of life of these insured persons has increased three years in the past decade, and more than eight years since 1938. "In 1909, the expectation of life at birth among the insured persons was about six years less than that for the population as a whole; at present the two are on a par," the statisticians note.

Surgeons Form Trauma Section.—The United States Section, International College of Surgeons, has formed the Section on Surgery of Trauma as a successor to the Section on Occupational Surgery. Dr. Chester C. Guy, clinical associate professor of surgery at the University of Illinois College of

Medicine, Chicago, is chairman of the section and Dr. N. Gillmor Long, Evanston, is co-chairman and secretary. The Section on Surgery of Trauma will provide a forum for those surgeons whose work is limited to traumatic lesions and for those who treat lesions frequently in their daily practice. The section "will deal with developments in the treatments of specific injuries, consider programs for the prevention of injuries, conduct studies on basic physiologic and pathologic changes in the injured person, and give thought to allied subjects."

Institute to Study Gravitational Strain.—The Institute for Gravitational Strain Pathology, Inc., a new research institute, studies the specific and general ill effects of gravitation on man. The institute represents a scientific, educational, nonprofit organization, incorporated in the State of New York, and is supported by philanthropic funds. Clinical experimentation is carried out by means of a special tool ("antigravitation leverage technique") designed to modify the pathogenic thrust of gravity on the living human being. Involved are the pathology of man's upright posture, human energetics, the processes of stress and strain, and of chronic fatigue. The present topic of the investigations is the "low-back problem." Reports on the institute's work will be published. For information write Dr. Martin Jungmann, Director, Institute for Gravitational Strain Pathology, 1384 Third Ave., New York 21.

Grants for Treatment and Research.—The National Foundation has announced treatment and research grants amounting to almost one million dollars in March of Dimes funds and including studies related to the problems of arthritis and birth defects. The National Foundation has expanded its program beyond polio to include viruses in general, disorders of the central nervous system, arthritis, and birth defects. Nine of the awards announced are for support of polio rehabilitation centers, part of a country-wide network of 15 March of Dimes-sponsored centers devoted to treatment of the aftereffects of polio. One grant was made in support of work at the Edward Daniels Faulkner Arthritis Clinic of the Presbyterian Hospital, New York City. The newly announced grants bring 1959 authorizations to a total of $4,030,045 in March of Dimes funds.

Prizes for Unpublished Monographs.—The American Academy of Arts and Sciences announced three prizes of $1,000 each to be awarded annually to the authors of "especially meritorious unpublished monographs" one each in the humanities, social sciences, and physical and biological sciences. A monograph is defined for the purposes of these awards as a "scholarly contribution to knowledge, too long for an article in a learned journal and too specialized or too short for a general book. Recipients of these prizes will be expected to make their own arrangements for publication. The final date in 1959 for receipt of manuscripts by the committee on awards is Oct. 1. Announcement of the awards will be made in December. Details may be secured on request from the Committee on Monograph Prizes, American Academy of Arts and Sciences, 280 Newton St., Brookline Station, Boston 46.

Committee on Research for National Foundation.—Fourteen U. S. scientists have been named to guide the expanded medical and scientific research program of The National Foundation as it begins its work on arthritis, birth defects, central nervous system disorders, and virus diseases in general. Headed by the president of the University of Southern California, Dr. Norman H. Topping, a new medical advisory Committee on Research to pass on all grants for research projects supported by March of Dimes funds was announced by Basil O'Connor, president of the foundation. The new committee replaces the former Committee on Virus Research and Epidemiology, which had eight members. It includes experts in the fields of arthritis, congenital malformations, virology, biochemistry, bacteriology, genetics, and immunology. Dr. Thomas B. Turner, dean of the Medical Faculty, Johns Hopkins University, Baltimore, is vice-chairman of the committee.

Centennial for Dental Association.—"A century of health service" will be evaluated in a special centennial issue of *The Journal of the American Dental Association* to be published in June. Many authorities have contributed to the 256-page number commemorating the 100th anniversary of the association. Congratulatory messages, ranging from those from President Eisenhower, the U. S. Congress, and Secretary Flemming of the Department of Health, Education, and Welfare to the presidents of such groups as the American Medical Association, American Hospital Association, American Bar Association, World Health Organization, American Public Health Association, American Pharmaceutical Association, National Dairy Council, and the American Public Welfare Association will be included. The publication will also contain a number of historical pictures indicating highlights in organized dentistry's growth as well as pictures showing activities in which the profession is engaged today.

Arrangements, Transportation for World Meetings.—Dr. Louis H. Bauer, secretary-general, World Medical Association, has announced that the association has made initial arrangements for providing its participants at the Second World Conference on Medical Education, Chicago, Aug. 30-Sept. 4, and the eighth general assembly of the World Medical Association (Montreal, Canada, Sept. 7-12) with a special chartered transportation plan. Members of the national medical associations and their families are eligible to apply for reservations on the chartered flights. Dr. Bauer noted that the conference dates fell during the "peak season" of tourist travel which might make it more difficult for the participants to obtain the regular commercial reservations they wished, and that the plan would provide substantial financial savings for the member associations, their delegates, and participants at the meetings. Additional information may be obtained from The World Medical Association, 10 Columbus Circle, New York 19.

Maxillofacial Surgeons Meet in Chicago.—The 13th annual meeting of the American Society of Maxillofacial Surgeons will be held May 10-13 at the Palmer House, Chicago. Five symposiums will be presented under the following titles and moderators:

Oral Lesions, Dr. Casper Epsteen, Chicago.
Surgical Repair of Cleft Palate, Dr. Fred S. Dunn, New York City.
Treatment of Malignant Diseases of the Head and Neck, Dr. Arthur Dick, Washington, D. C.
Tumors of the Salivary Glands, Dr. Orion H. Stuteville, Chicago.
Traumatic Injuries of the Face and Head, Dr. Walter W. Dalitsch, Chicago.

Two movies are planned: "Mandibular Prognathism" and "Open Vertical Subcondylectomy for Correction of Prognathism." The dinner is planned for May 12, 8 p.m. A panel on "Burns of the Face and Mouth," moderated by Dr. Louis W. Schultz, Chicago, will conclude the meeting. For information, write Dr. O. H. Stuteville, Secretary, American Society of Maxillofacial Surgeons, 700 N. Michigan Ave., Chicago 11.

Cancer Among Children.—Cancer currently causes about 4,000 deaths a year in the United States among children under 15 years of age, it is reported by statisticians of the Metropolitan Life Insurance Company. This is nearly 50% higher than the toll only a decade ago, reportedly reflecting in part the rapid growth of the child population. In the 5-14 age group, cancer takes more lives than any other disease, accounting for one out of every four deaths from disease. The death rate from cancer in childhood is highest at the preschool ages, rising gradually to a peak between ages three and four, the statisticians point out. At each of the childhood ages, the rate among boys exceeds that among girls by one-fifth. Leukemia is the most common form of cancer in childhood, being responsible for nearly half the cancer death toll at ages under 15. Cancers of the nervous system—chiefly the brain—constitute the second most frequent category and account for about one-fifth of all deaths from cancer in childhood. Other fairly frequent sites of childhood cancer are the kidney and bone.

Grants for Virus Research.—The sum of $1,040,750 was appropriated by the Rockefeller Foundation for the support of its operating program in the investigation and control of virus diseases during the calendar year 1959. This program is conducted by members of the foundation's professional staff in central laboratories in New York City and in cooperative field laboratories in India, South Africa, Trinidad, Brazil, and California. The program is at present concentrated on the viruses which are transmitted by insects and ticks and which infect birds, the lower mammals, and man. The program began in 1949 with the study of about 15 viruses which had been discovered but not identified during work on the yellow fever virus. This investigation culminated in the production of a vaccine which has reportedly reduced yellow fever to a minor role as a public health threat. More than 70 "arbor" (ARthropod-BORne) viruses have been isolated and identified in the intervening years, and the relation of a number of them to serious human infections and to animal diseases of economic importance has been established.

Morbidity Report.—About 438 million acute illnesses involving either restricted activity or medical attention or both occurred among the American people during the year ending June 30, 1958. The number of such illnesses averaged 2.6 for every person in the population. The figures are from the U. S. National Health Survey, which shows that the incidence was highest in the youngest age groups and decreased progressively in each older age group. The rates ranged from an average of 4 illnesses among children under 5 to 1.6 illnesses per person 65 or over. The incidence rate among females was slightly higer than for males. Respiratory ailments accounted for 65% of all the illness involving medical attention or restricted activity. The respiratory illnesses caused 1,172 million days of restricted activity, or an average of 7 days per person. About half of this time involved bed disability. The days of restricted activity included 219 million days lost from work, and 196 million days lost from school. The incidence of these illnesses reportedly reflects the impact of the Asian influenza epidemic which occurred during the year.

Plan Nation-Wide Atomic Fall-Out Measurements.—The U. S. will have a nation-wide monitoring network to measure atomic fall-out "within a matter of months," Mr. Lewis Berry, assistant director for plans and operations of the Office of Civil Defense Mobilization (OCDM) reported March 12 at the University of Michigan, Ann Arbor. The network would be established in existing federal installations, including airport control towers, weather bureaus, and forest-ranger stations. Mr. Berry said nonmilitary defense planning "is now over the hump," citing these signs of progress:

1. Preparation of a national plan for nonmilitary defense, which is now being supplemented with state and local plans;
2. Development of matching fund programs for training of personnel and other federal-state activities in this field; and
3. Planning for continuity of government at all levels in the event of a national emergency or enemy attack.

OCDM is encouraging states to select alternate sites for government headquarters, to provide for preservation of key records, and to develop plans for complete use of state personnel and facilities in emergencies, Mr. Berry said.

Committee on Education for National Foundation.—To guide the expanded program of education for the health professions of The National Foundation as it moves into the fields of birth defects and arthritis, a new Committee on Professional Education has been announced by Basil O'Connor, president of the organization (originally known as the National Foundation for Infantile Paralysis). The committee is headed by Dr. Thomas B. Turner, dean of the Medical Faculty, Johns Hopkins University, Baltimore. Dr. Turner is also vice-chairman of the National Foundation Committee on Research. The function of the committee is to advise The National Foundation in allocating March of Dimes funds to help increase the nation's reservoir of qualified scientific investigators and trained health personnel. In its 21-year history, March of Dimes assistance for specialized training has been given to more than 7,000 students. One of the first undertakings of the committee will be to guide the development of The National Foundation's new 12-million-dollar health scholarship plan, wherein 505 four-year college scholarships will be offered annually in nursing, medical social work, physical therapy, occupational therapy, and medicine.

Awards for Research.—Nine U. S. scientists received Borden Awards of a gold medal and $1,000 during 1958 "for outstanding research achievements." The 1958 winners' scientific contributions are reviewed in an annual directory released by the Borden Company Foundation. Administered by professional and scientific associations, 161 Borden awards have been made by the foundation since the program was initiated in 1937. The administering groups and the 1958 winners are:

The American Chemical Society—William G. Gordon, Ph.D., Eastern Regional Research Laboratory, U. S. Department of Agriculture, for contributions in the fundamental chemistry of milk products.

The American Dairy Science Association—W. James Harper, Ph.D., Ohio State University, for contributions in dairy bacteriology and biochemistry.

The American Dairy Science Association—Jay L. Lush, Ph.D., Iowa State College, for research in the genetics and breeding of dairy cattle.

The American Home Economics Association—May S. Reynolds, Ph.D., University of Wisconsin, for research in protein metabolism.

The Association of American Medical Colleges—Dr. Severo Ochoa, department of biochemistry, New York University, for research on the enzymatic mechanisms of metabolism.

The American Institute of Nutrition—Lemuel D. Wright, Ph.D., Graduate School of Nutrition, Cornell University, for the development of microbiological assay procedures for vitamins and the discovery of biocytin.

The American Academy of Pediatrics—Dr. Charles D. May, College of Physicians and Surgeons, Columbia University, for contribution to long-term metabolic studies of infants fed human milk.

The Loultry Science Association—George M. Briggs, Ph.D., Laboratory of Nutrition and Endocrinology, National Institutes of Health, Bethesda, Md., for basic research in the area of Nutritional interrelationships.

The American Veterinary Medical Association—Chester A. Manthei, D.V.M., U. S. Department of Agriculture, Beltsville, Md., for research in the control and eradication of brucellosis in dairy cattle.

Medical Aid Team Goes to Viet Nam.—The first contingent of a U. S. medical team left San Francisco March 30 on an emergency volunteer mission to the Cho Ray Hospital at the University of Saigon, Viet Nam. They are Dr. Richard H. Overholt, clinical professor of surgery, Tufts Medical School, Boston; Dr. Max S. Sadove, professor of surgery (anesthesiology), University of Illinois Medical College, Chicago; Miss Kathryn O'Donnell, R.N., chief nurse of the thoracic clinic, Overholt Clinic in Boston; and Miss Shirley S. Wolf, R.N., surgical nurse of the University of Maryland Medical School Hospital, Baltimore. Sponsored by MEDICO, the group, eventually to total seven, is responding to a request of the government of Viet Nam for aid in "clearing up a backlog of pulmonary tuberculosis cases threatening to overwhelm the limited medical facilities" of that Asian country. They will also demonstrate up-to-date methods of treatment of lung diseases. Tuberculosis is the major health menace of Viet Nam, accounting for 80% of deaths. Drs. Overholt and Sadove will be in Saigon from April 1 to June 1. They will be jointed on May 1 by Dr. James B. Littlefield, assistant professor of surgery, University of Virginia Medical School, Charlottesville, and Dr. Peter J. Safar, chief of anesthesiology, Baltimore City Hospitals, both of whom will remain until July 1. The remaining member of the team, Dr. John M. Keshishian, instructor in surgery, George Washington University Medical School, Washington, D. C., plans to be at the Saigon Hospital from June 15 to Aug. 15. Nurses Wolf and O'Donnell will remain for four months, April 1 to Aug. 1. MEDICO (Medical International Cooperation) is a private, nonprofit and nonsectarian organization for American medical assistance to the newly developing countries of Asia, Africa, and Latin America. Its honorary patron is Dr. Albert Schweitzer, and its secretary general is Dr. Peter D. Comanduras. Among the other medical projects it supports are the work of Dr. Thomas A. Dooley in Laos, Dr. Gordon Seagrave (the "Burma Surgeon") in Burma, Dr. Albert Schweitzer in Gabon, Central Africa; Dr. Theodor Binder in Peru, Dr.

Karl Erben in Pakistan, and Dr. Louis Mars in Haiti. MEDICO is a division of the International Rescue Committee, a 25-year-old refugee welfare organization.

CORRECTIONS

Nerve Block for Surgery of the Hand and Forearm.—In Dr. Preston J. Burnham's paper entitled "Simple Regional Nerve Block for Surgery of the Hand and Forearm" (Feb. 28, page 941) in the third line of the second paragraph the word "accomplished" was in error and the word should have been "accompanied."

Poliomyelitis Vaccine Preparation and Administration.—In the article by Dr. Salk (April 18, page 1829) entitled "Poliomyelitis Vaccine Preparation and Administration," the last sentence of the initial boxed summary should have read as follows: The substantial rise in antibody titer induced by a fourth dose of a selected lot of vaccine suggested that failure of previous injection was probably due to the use of vaccines of less than optimal potency.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written*, Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Chicago, June 2-4. The deadline for filing applications was April 1. Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. A Special Examination in Nuclear Medicine (for diplomates in Radiology or Therapeutic Radiology) will not be given in June 1959. Candidates desiring this examination will be accommodated at the meeting of the Board in Washington, D. C. on December 5. Deadline for filing application is August 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. *Final date for filing application* is July 1. *Oral.* September. *Final date for filing application* is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. *Final date for filing application is* Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

DEATHS

Connell, Isce Lee Ⓜ Jacksonville, Fla.; University of Chicago, The School of Medicine, 1930; veteran of World Wars I and II; recipient of University of Chicago Alumni Foundation Award of Merit for leadership in fund raising; served as health officer of Cleburne County and Clarke County, Ala.; died Feb. 14, aged 66.

Crooks, William James Ⓜ Clinton, N. J.; Tufts College Medical School, Boston, 1932; on the staff of the Clara Maas Hospital in Belleville; died Feb. 14, aged 57.

D'Amico, Joseph Ⓜ New Haven, Conn.; Regia Universitá degli Studi di Roma. Facoltà di Medicina e Chirurgia, Italy, 1937; interned at Hospital of St. Raphael; member of the American Academy of General Practice; died Feb. 11, aged 51.

Darling, Frank Edward Sr. Ⓜ Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; served on the faculty of his alma mater; at one time registrar of vital statistics for the city health department; during World War I was in charge of surgical services at a base hospital in France; associated with St. Joseph's Hospital in West Bend, St. Alphonsus Hospital in Port Washington, St. Joseph's Hospital in Hartford, and St. Michael Hospital; died Feb. 13, aged 79.

Davis, Emmer Palmore, Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1912; veteran of World War I; served with the Veterans Administration in Phoenix, Ariz.; died Feb. 3, aged 74.

Dessau, Frederick Isaac Ⓜ Nyack, N. Y.; born in Hamburg, Germany, March 23, 1910; Hamburgische Universität Medizinische Fakultät, Hamburg, Germany, 1937; specialist certified by the American Board of Pathology; certified by the National Board of Medical Examiners; member of the American Trudeau Society, American Association of Pathologists and Bacteriologists, and the College of American Pathologists; head pathologist at the Lederle Laboratories at Pearl River; instructor of pathology at Harvard Medical School in Boston from 1939 to 1943; research fellow at Yale University in New Haven, Conn., from 1939 to 1943; died in the Presbyterian Hospital in New York City Feb. 23, aged 48.

Dorsey, Thomas Manning Ⓜ Louisville, Ky.; University of Louisville Medical Department, 1912; served overseas during World War I; formerly on the faculty of his alma mater; associated with SS Mary and Elizabeth Hospital, St. Anthony's Hospital, and Louisville City Hospital; died in St. Joseph Infirmary Feb. 13, aged 72.

Downs, Lawrence Ethridge Ⓜ Los Angeles; University of Louisville (Ky.) Medical Department, 1912; member of the International College of Surgeons; on the governor's staff of the examining board in the state of Kansas during World War I; served on the Los Angeles examining board of Selective Service during World War II; a member of the Hollywood Academy of Medicine, from which organization he received an award on Feb. 12, 1959, for 25 years of active service; one of the founders of the Hollywood Presbyterian Hospital, where he was on the staff for 25 years; died Feb. 18, aged 75.

Dragoo, Farrol Andrew Ⓜ Middletown, Ind.; Indiana University School of Medicine, Indianapolis, 1932; veteran of World War II; on the staff of St. John's Hospital in Anderson and the Henry County Hospital in New Castle, where he died Feb. 1, aged 54.

Du Bois, Eugene Floyd, New York City; born in West New Brighton, N. Y., June 4, 1882; Columbia University College of Physicians and Surgeons, New York City, 1906; specialist certified by the American Board of Internal Medicine; since 1950 emeritus professor of physiology at Cornell University Medical College, where he joined the faculty in 1910 as an instructor in applied pharmacology, subsequently serving as associate professor of medicine, professor of medicine, and professor of physiology; medical director of the Russell Sage Institute of Pathology from 1913 to 1950; veteran of World War I and was awarded the Navy Cross; served during World War II; chairman of the committee on aviation medicine of the National Research Council from 1940 to 1945; member and past-vice-president of the Association of American Physicians and in 1947 received its Kober Medal; member of the American Society of Clinical Investigation and the Aero Medical Association; fellow of the American College of Physicians and in April was to have received its John Phillips Memorial Award in Chicago; from 1932 to 1941 physician in chief at the New York Hospital; for many years associated with the Bellevue Hospital; author of "Basal Metabolism in Health and Disease"; received the degree of doctor of science, University of Rochester, in 1948; died Feb. 12, aged 76.

Ⓜ Indicates Member of the American Medical Association.

South Bend, Ind.; Univer-
School of Medicine, Baltimore,
World War I; served as superin-
County Tuberculosis Hospital;
and St. Joseph's hospitals;

Lincoln, Neb.; John A.
Omaha, 1913; veteran
member of the board
member of the state
consultant to the Veterans
rehabilitation work with dis-
died in St. Joseph's Hospital,
Feb. 6, aged 69.

Otto Ⓜ Colorado Springs, Colo.; Eberhard-Karls-Universität-Medizinische Fakultät, Tübingen, Wurtemberg, Germany, 1900; member of the American Trudeau Society; served a residency at the Modern Woodmen of America Sanatorium in Woodmen; resident at the Cragmor Foundation; associated with Glockner and St. Francis hospitals; died Feb. 9, aged 82.

Failmezger, Theodore Richard Ⓜ Clearwater, Fla.; born in Brooklyn Aug. 20, 1904; Jefferson Medical College of Philadelphia, 1934; also a graduate in pharmacy; specialist certified by the American Board of Internal Medicine; interned at the Orange Memorial Hospital in Orange, N. J.; served a residency in medicine at the New York Post-Graduate Medical School and Hospital in New York City; member of the American Rheumatism Association, American Geriatrics Association, New Jersey Heart Association, and the New Jersey Diabetes Association; fellow of the American College of Physicians; veteran of World War II; at one time practiced in Madison, N. J., where he was president of the board of health from 1937 to 1939, and from 1937 to 1957 physician to Drew University; served on the staffs of the New York Post-Graduate Medical School and Hospital in New York City, New Jersey Orthopaedic Hospital in Orange, N. J., and the All Souls and Morristown Memorial hospitals in Morristown, N. J.; on the staff of the Morton Plant Hospital; died Feb. 7, aged 54.

Ferrell, Grover C., Eldorado, Ill.; Chicago College of Medicine and Surgery, 1912; past-president of the Saline County Medical Society
eon for
Louis-
New York Central, Illi

chairman of the South Carolina School Boards; on the staffs of the Saunders Memorial Hospital and McLeod Infirmary, where he died Feb. 7, aged 63.

Flude, John Meredith Ⓜ Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1918; served as western field representative of the American Society for the Control of Cancer; formerly medical supervisor for the department of social security in the state of Washington; associated with the Community Hospital and the Seaside Hospital, where he died Feb. 9, aged 65.

Fuller, Homer Gifford Ⓜ Washington, D. C.; George Washington University School of Medicine, Washington, 1904; specialist certified by the American Board of Urology; member of the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; served on the faculty of his alma mater; for many years on the staff of the Garfield Memorial Hospital; died in the Doctor's Hospital Feb. 13, aged 80.

Gebert, Clara McGrew Ⓜ Valley Park, Mo.; St. Louis College of Physicians and Surgeons, 1922; died Feb. 18, aged 74.

Gladstone, William R. Ⓜ Walton, N. Y.; Bellevue Hospital Medical College, New York City, 1898; served on the staff of the Delaware Valley Hospital; died Feb. 2, aged 87.

Gold, Joseph Brand Ⓜ Santa Fe, N. M.; University of Pittsburgh School of Medicine, 1914; served overseas during World War I; formerly practiced in Pittsburgh, where he was on the staffs of Mercy and Passavant hospitals; died Feb. 8, aged 69.

Goodrich, William Albert Ⓜ Hartford, Conn.; born in Waterbury, Oct. 4, 1909; Columbia University College of Physicians and Surgeons, New York City, 1935; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society and Radiological Society of North America; counselor for Connecticut of the American College of Radiology; a past-president and secretary treasurer of the radiology section of the Connecticut State Medical Society; veteran of World War II; on the staffs of the Charlotte Hungerford Hospital in Torrington, Johnson Memorial Hospital in Stafford Springs, and the Hartford Hospital, where he died Feb. 11, aged 49.

, Edmund Alphonse Ⓜ Toledo, Ohio; Uni-
Michigan Medical School, Ann Arbor,
St. Vincent's Hospital Jan. 26, aged 55.

ramwell Ⓜ Austin, Minn.; Western
School of Medicine, Cleveland,
president of the Mower County
a trustee of the Macalester Col-
staff member of St. Olaf Hospital,
. 20, aged 73.

Groves, Robert Burwell, Lowell, N. C.; Medical College of Virginia, Richmond, 1924; past-president of the Gaston County Medical Society; veteran of World War I; a member of the staffs of Gaston Memorial and Garrison General hospitals; died in Charlotte Feb. 8, aged 60.

Gsell, Jacob Franklin Ⓜ Wichita, Kan.; Rush Medical College, Chicago, 1895; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; charter member and first president of the Sedgwick County Medical Society; past-president of the Kansas Medical Society; on the staff of St. Francis Hospital; died Feb. 12, aged 85.

Hall, Allon Killough, La Porte, Texas; Tulane University School of Medicine, New Orleans, 1946; member of the American Academy of General Practice; interned at Scott and White Hospital in Temple; served a residency at the Veterans Administration Hospital in Houston; for two years a flight surgeon in the Air Force; associate professor of ophthalmology at Baylor University College of Medicine in Houston; on the staff of San Jacinto Memorial Hospital in Baytown; died Feb. 7, aged 35.

Harber, Harry Paul Ⓜ Dallas, Texas; University of Texas School of Medicine, Galveston, 1917; on the faculty of Baylor University College of Medicine in Houston; on the staffs of the Baylor University, St. Paul's and Medical Arts hospitals; died Feb. 3, aged 68.

Harris, Benjamin Henry Ⓜ Philadelphia; Temple University School of Medicine, Philadelphia, 1919; died Feb. 8, aged 63.

Harrison, H. Wesley Ⓜ Detroit; University of Michigan Medical School, Ann Arbor; 1924; medical director of the Alcoa–Aluminum Company of America; an executive board member and secretary treasurer of the medical staff at St. Joseph Mercy Hospital, where he died Feb. 3, aged 58.

Hebald, Selian Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1919; received a Presidential Citation for his work with the Selective Service system during World War II; founding member of the American Academy of Allergy; associated with the Hospital for Joint Diseases and Roosevelt Hospital; died Feb. 17, aged 63.

Hines, Sidney Gilbert, Grayson, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; died in Alexandria Feb. 2, aged 75.

Hollander, Lester Ⓜ Pittsburgh; University of Pittsburgh School of Medicine, 1912; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology and the American Radium Society; fellow of the American College of Physicians; founder and director of the Pittsburgh Skin and Cancer Foundation; affiliated with the Montefiore Hospital; died Feb. 2, aged 68.

Holmes, Prince Albert, Mount Vernon, Mo.; St. Louis College of Physicians and Surgeons, 1909; died in Springfield Baptist Hospital in Springfield Feb. 2, aged 79.

Howard, Walter M. Ⓜ Joplin, Mo.; Washington University School of Medicine, St. Louis, 1930; member of the staffs of Freeman Hospital and St. John's Hospital, where he died Jan 7, aged 53.

Hull, Chloe Frances, Laramie, Wyo.; Medical College of Indiana, Indianapolis, 1902; for many years a medical missionary in India; died in the Wyoming State Hospital, Evanston, Jan. 26, aged 84.

Jakobson, Ber, Rome, N. Y.; University of Kharkov Faculty of Medicine, Russia, 1914; medical officer in the Russian Army during World War I; associated with the Rome State School; died in Rome Hospital Feb. 4, aged 68.

Jensen, Gordon Melvin Ⓜ Logan, Utah; Medical College of South Carolina, Charleston, 1943; interned at St. Vincent's Hospital in Portland, Ore.; formerly a resident at the Veterans Administration Hospital in Salt Lake City; veteran of World War II; on the staffs of the Latter Day Saints Hospital; died in Salt Lake City Feb. 3, aged 45.

Johnston, Robert Sherwood, Chana, Ill.; Illinois Medical College, Chicago, 1904; served on the staff of St. Anthony Hospital in Rockford; died Feb. 5, aged 86.

Kallus, Edward John Ⓜ Colonel, U. S. Army, retired, Lufkin, Texas; University of Texas School of Medicine, Galveston, 1922; entered the regular Army in 1924; veteran of World War II; retired July 31, 1948; member of the Radiological Society of North America; died Feb. 6, aged 61.

Kamerer, Russell Peter Ⓜ Perryopolis, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; died in the Western Pennsylvania Hospital, Pittsburgh, Feb. 9, aged 80.

Kent, Louis Clarence, Manchester, Mich.; Detroit College of Medicine, 1901; served as village president, president of the Manchester school board, and village council member; died in the Herrick Memorial Hospital, Tecumseh, Feb. 21, aged 91.

Kenyon, Frances Aureola Ⓜ Woodville, R. I.; the Hahnemann Medical College and Hospital, Chicago, 1894; for 32 years medical examiner of Washington County; served as Richmond town health officer and school physician; for many years school

Duggan, James Archie Ⓜ South Bend, Ind.; University of Maryland School of Medicine, Baltimore, 1912; veteran of World War I; served as superintendent of St. Joseph County Tuberculosis Hospital; associated with Memorial and St. Joseph's hospitals; died Feb. 10, aged 69.

Edwards, Charles B., Lincoln, Neb.; John A. Creighton Medical College, Omaha, 1913; veteran of World War I; served as a member of the board of education in Kearney; member of the state board of health; formerly consultant to the Veterans Administration for rehabilitation work with disabled veterans; died in St. Joseph's Hospital, Phoenix, Ariz., Feb. 6, aged 69.

Einstein, Otto Ⓜ Colorado Springs, Colo.; Eberhard-Karis-Universität-Medizinische Fakultät, Tübingen, Würtemberg, Germany, 1900; member of the American Trudeau Society; served a residency at the Modern Woodmen of America Sanatorium in Woodmen; resident at the Cragmor Foundation; associated with Glockner and St. Francis hospitals; died Feb. 9, aged 82.

Failmezger, Theodore Richard Ⓜ Clearwater, Fla.; born in Brooklyn Aug. 20, 1904; Jefferson Medical College of Philadelphia, 1934; also a graduate in pharmacy; specialist certified by the American Board of Internal Medicine; interned at the Orange Memorial Hospital in Orange, N. J.; served a residency in medicine at the New York Post-Graduate Medical School and Hospital in New York City; member of the American Rheumatism Association, American Geriatrics Association, New Jersey Heart Association, and the New Jersey Diabetes Association; fellow of the American College of Physicians; veteran of World War II; at one time practiced in Madison, N. J., where he was president of the board of health from 1937 to 1939, and from 1937 to 1957 physician to Drew University; served on the staffs of the New York Post-Graduate Medical School and Hospital in New York City, New Jersey Orthopaedic Hospital in Orange, N. J., and the All Souls and Morristown Memorial hospitals in Morristown, N. J.; on the staff of the Morton Plant Hospital; died Feb. 7, aged 54.

Ferrell, Grover C., Eldorado, Ill.; Chicago College of Medicine and Surgery, 1912; past-president of the Saline County Medical Society; surgeon for the New York Central, Illinois Central and Louisville and Nashville Railroad companies; associated with Ferrell Hospital, where he died Feb. 4, aged 72.

Finklea, Orion Tiverton Ⓜ Florence, S. C.; Medical College of South Carolina, Charleston, 1918; member of the Southeastern Surgical Congress and the American Urological Association; fellow of the American College of Surgeons; for eight years chairman of the city school board and two years chairman of the South Carolina School Boards; on the staffs of the Saunders Memorial Hospital and McLeod Infirmary, where he died Feb. 7, aged 63.

Flude, John Meredith Ⓜ Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1918; served as western field representative of the American Society for the Control of Cancer; formerly medical supervisor for the department of social security in the state of Washington; associated with the Community Hospital and the Seaside Hospital, where he died Feb. 9, aged 65.

Fuller, Homer Gifford Ⓜ Washington, D. C.; George Washington University School of Medicine, Washington, 1904; specialist certified by the American Board of Urology; member of the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; served on the faculty of his alma mater; for many years on the staff of the Garfield Memorial Hospital; died in the Doctor's Hospital Feb. 13, aged 80.

Gebert, Clara McGrew Ⓜ Valley Park, Mo.; St. Louis College of Physicians and Surgeons, 1922; died Feb. 18, aged 74.

Gladstone, William R. Ⓜ Walton, N. Y.; Bellevue Hospital Medical College, New York City, 1898; served on the staff of the Delaware Valley Hospital; died Feb. 2, aged 87.

Gold, Joseph Brand Ⓜ Santa Fe, N. M.; University of Pittsburgh School of Medicine, 1914; served overseas during World War I; formerly practiced in Pittsburgh, where he was on the staffs of Mercy and Passavant hospitals; died Feb. 8, aged 69.

Goodrich, William Albert Ⓜ Hartford, Conn.; born in Waterbury, Oct. 4, 1909; Columbia University College of Physicians and Surgeons, New York City, 1935; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society and Radiological Society of North America; counselor for Connecticut of the American College of Radiology; a past-president and secretary treasurer of the radiology section of the Connecticut State Medical Society; veteran of World War II; on the staffs of the Charlotte Hungerford Hospital in Torrington, Johnson Memorial Hospital in Stafford Springs, and the Hartford Hospital, where he died Feb. 11, aged 49.

Gomolski, Edmund Alphonse Ⓜ Toledo, Ohio; University of Michigan Medical School, Ann Arbor, 1930; died in St. Vincent's Hospital Jan. 26, aged 55.

Grise, William Bramwell Ⓜ Austin, Minn.; Western Reserve University School of Medicine, Cleveland, 1914; served as president of the Mower County Medical Society; a trustee of the Macalester College in St. Paul; a staff member of St. Olaf Hospital, where he died Feb. 20, aged 73.

Groves, Robert Burwell, Lowell, N. C.; Medical College of Virginia, Richmond, 1924; past-president of the Gaston County Medical Society; veteran of World War I; a member of the staffs of Gaston Memorial and Garrison General hospitals; died in Charlotte Feb. 8, aged 60.

Gsell, Jacob Franklin Ⓜ Wichita, Kan.; Rush Medical College, Chicago, 1895; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; charter member and first president of the Sedgwick County Medical Society; past-president of the Kansas Medical Society; on the staff of St. Francis Hospital; died Feb. 12, aged 85.

Hall, Allon Killough, La Porte, Texas; Tulane University School of Medicine, New Orleans, 1946; member of the American Academy of General Practice; interned at Scott and White Hospital in Temple; served a residency at the Veterans Administration Hospital in Houston; for two years a flight surgeon in the Air Force; associate professor of ophthalmology at Baylor University College of Medicine in Houston; on the staff of San Jacinto Memorial Hospital in Baytown; died Feb. 7, aged 35.

Harber, Harry Paul Ⓜ Dallas, Texas; University of Texas School of Medicine, Galveston, 1917; on the faculty of Baylor University College of Medicine in Houston; on the staffs of the Baylor University, St. Paul's and Medical Arts hospitals; died Feb. 3, aged 68.

Harris, Benjamin Henry Ⓜ Philadelphia; Temple University School of Medicine, Philadelphia, 1919; died Feb. 8, aged 63.

Harrison, H. Wesley Ⓜ Detroit; University of Michigan Medical School, Ann Arbor; 1924; medical director of the Alcoa–Aluminum Company of America; an executive board member and secretary treasurer of the medical staff at St. Joseph Mercy Hospital, where he died Feb. 3, aged 58.

Hebald, Selian Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1919; received a Presidential Citation for his work with the Selective Service system during World War II; founding member of the American Academy of Allergy; associated with the Hospital for Joint Diseases and Roosevelt Hospital; died Feb. 17, aged 63.

Hines, Sidney Gilbert, Grayson, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; died in Alexandria Feb. 2, aged 75.

Hollander, Lester Ⓜ Pittsburgh; University of Pittsburgh School of Medicine, 1912; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology and the American Radium Society; fellow of the American College of Physicians; founder and director of the Pittsburgh Skin and Cancer Foundation; affiliated with the Montefiore Hospital; died Feb. 2, aged 68.

Holmes, Prince Albert, Mount Vernon, Mo.; St. Louis College of Physicians and Surgeons, 1909; died in Springfield Baptist Hospital in Springfield Feb. 2, aged 79.

Howard, Walter M. Ⓜ Joplin, Mo.; Washington University School of Medicine, St. Louis, 1930; member of the staffs of Freeman Hospital and St. John's Hospital, where he died Jan 7, aged 53.

Hull, Chloe Frances, Laramie, Wyo.; Medical College of Indiana, Indianapolis, 1902; for many years a medical missionary in India; died in the Wyoming State Hospital, Evanston, Jan. 26, aged 84.

Jakobson, Ber, Rome, N. Y.; University of Kharkov Faculty of Medicine, Russia, 1914; medical officer in the Russian Army during World War I; associated with the Rome State School; died in Rome Hospital Feb. 4, aged 68.

Jensen, Gordon Melvin Ⓜ Logan, Utah; Medical College of South Carolina, Charleston, 1943; interned at St. Vincent's Hospital in Portland, Ore.; formerly a resident at the Veterans Administration Hospital in Salt Lake City; veteran of World War II; on the staffs of the Latter Day Saints Hospital; died in Salt Lake City Feb. 3, aged 45.

Johnston, Robert Sherwood, Chana, Ill.; Illinois Medical College, Chicago, 1904; served on the staff of St. Anthony Hospital in Rockford; died Feb. 5, aged 86.

Kallus, Edward John Ⓜ Colonel, U. S. Army, retired, Lufkin, Texas; University of Texas School of Medicine, Galveston, 1922; entered the regular Army in 1924; veteran of World War II; retired July 31, 1948; member of the Radiological Society of North America; died Feb. 6, aged 61.

Kamerer, Russell Peter Ⓜ Perryopolis, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; died in the Western Pennsylvania Hospital, Pittsburgh, Feb. 9, aged 80.

Kent, Louis Clarence, Manchester, Mich.; Detroit College of Medicine, 1901; served as village president, president of the Manchester school board, and village council member; died in the Herrick Memorial Hospital, Tecumseh, Feb. 21, aged 91.

Kenyon, Frances Aureola Ⓜ Woodville, R. I.; the Hahnemann Medical College and Hospital, Chicago, 1894; for 32 years medical examiner of Washington County; served as Richmond town health officer and school physician; for many years school physician in Hopkinton; chosen in 1956 as "Woman of the Year" by the Westerly Quota Club, of which she was a member; associated with Roger Williams General Hospital in Providence and the Westerly (R. I.) Hospital; died Feb. 15, aged 87.

Kerley, William Wilburn Ⓜ Anadarko, Okla.; Arkansas Industrial University Medical Department, Little Rock, 1898; past-president of the Oklahoma State Medical Association and the Caddo County Medical Society; county coroner; died Feb. 27, aged 87.

Kinsey, Ernest Schroeder Ⓜ Syracuse, N. Y.; Syracuse University College of Medicine, 1941; on the courtesy staff of Syracuse General and Crouse Irving hospitals; died in St. Joseph's Hospital Feb. 18, aged 41.

Klug, Oscar C. Ⓜ East St. Louis, Ill.; Chicago College of Medicine and Surgery, 1913; on the staffs of St. Mary's and Christian Welfare hospitals; died in the Memorial Hospital, Belleville, Feb. 6, aged 77.

Konheim, Vladimir M. Ⓜ Poughkeepsie, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1928; served on the staff of the Montefiore Hospital in New York City; consultant in dermatology at the Wassaic State School in Wassaic, Harlem Valley State Hospital, Wingdale, Northern Dutchess Health Center in Rhinebeck, and St. Francis Hospital and the Vassar Brothers Hospital, where he died Feb. 15, aged 66.

Kuntz, Wesley W. Ⓜ Barry, Ill.; Northwestern University Medical School, Chicago, 1905; veteran of the Spanish-American War and World War I; died Feb. 1, aged 83.

LaMont, Wyant Ⓜ Beverly Hills, Calif.; Rush Medical College, Chicago, 1925; certified by the National Board of Medical Examiners; veteran of World War II; member of the American Academy of General Practice; on the staffs of St. John's and Santa Monica hospitals in Santa Monica, and the Culver City (Calif.) Hospital, where he died Feb. 7, aged 59.

Landy, George Raymond Ⓜ Lansing, Mich.; University of Michigan Medical School, Ann Arbor, 1933; served as village health officer and village president in Eau Claire; clinic physician of the Ingham County Health Department; died Feb. 6, aged 52.

Lane, John Loftin Ⓜ Rocky Mount, N. C.; North Carolina Medical College, Davidson, 1906; on the staff of the Rocky Mount Sanitarium, where he died Jan. 30, aged 79.

Lankford, Joseph Frederick Ⓜ Lieut. Commander, U. S. Navy, retired, Albuquerque, N. M.; Indiana University School of Medicine, Indianapolis, 1909; veteran of World War I; entered the Navy in 1920 and retired June 30, 1941; died in the Veterans Administration Hospital Feb. 17, aged 73.

Laughlin, Zach Monroe, Phoenix, Ariz.; Central College of Physicians and Surgeons, Indianapolis, 1905; formerly associated with the Indian Service; died Jan. 30, aged 81.

Lawlor, Edward Francis, Waltham, Mass.; Boston University School of Medicine, 1935; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; veteran of World War II and was awarded the Bronze Star; on the staffs of the Massachusetts Eye and Ear Infirmary, Boston, Newton Wellesley Hospital in Wellesley, and Waltham (Mass.) Hospital, where he died Jan. 27, aged 47.

Le Compte, Elmo Mansfield, Springfield, Mo.; University of Louisville (Ky.) Medical Department, 1910; died Jan. 25, aged 76.

Lehrman, Raphael, Bayside, N. Y.; Long Island College Hospital, Brooklyn, 1918; died Dec. 2, aged 70.

McKee, Mary Ada Ⓜ Oil City, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1896; past-president of the medical staff and chief of the department of obstetrics at the Oil City Hospital, where in April, 1954, the M. Ada McKee Memorial Library was opened in her honor; in April, 1955, the Oil City Franklin Zonta Club honored her with a "This is Your Life" program and presented her with an honorary membership; in 1955 she received the Golden Deeds Award from the Oil City Exchange Club; died in the Oil City Hospital Feb. 6, aged 87.

McNamara, John Grover, Marion, Ohio; Starling-Ohio Medical College, Columbus, 1910; past-president of the Marion Academy of Medicine; veteran of World War I; past-president of the Marion County Agricultural Society; associated with the Marion General Hospital, where he died Feb. 13, aged 73.

Mackey, William Barry, Reagan, Texas; University of Nashville Medical Department, Nashville, Tenn., 1898; veteran of World War I; died in the Veterans Administration Hospital, Marlin, Jan. 24, aged 88.

Madler, Nicholas Allen Ⓜ Greeley, Colo.; Rush Medical College, Chicago, 1904; fellow of the American College of Surgeons; past-president of the Weld County Medical Society and the Colorado State Medical Society; at one time was the senior chief examiner of Colorado Selective Service System; associated with the Weld County General Hospital; one of the organizers of the Greeley

Kiwanis Club and was its first president in 1922; died in St. Joseph's Hospital, Denver, Feb. 6, aged 77.

Magson, Albert Edward Ⓜ Hightstown, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1938; died in the McKinley Hospital, Trenton, Feb. 1, aged 46.

Marel, Abraham Hersch Ⓜ Brooklyn; Medizinische Fakultät der Universität, Vienna, Austria, 1913; physician emeritus at Beth-El Hospital and consulting physician at Jewish Chronic Disease Hospital, where he was past-president of the medical board; died Dec. 22, aged 72.

Maxwell, Elmer Stephens Ⓜ Lexington, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; specialist certified by the American Board of Pathology; past-president of the Fayette County Medical Society; served overseas during World War I; member of the Central Society for Clinical Research, College of American Pathologists, and the American Society of Clinical Pathology; formerly on the faculty of his alma mater and the University of Louisville School of Medicine; member and past-president of the staff of Good Samaritan Hospital, where in 1956 the board of trustees named the new pathology laboratory after him; member and past-president of the staff of St. Joseph's Hospital, where he died Jan. 9, aged 70.

Mazzacano, Anthony Ferdinand, Flushing, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1931; veteran of World War II; died Dec. 21, aged 54.

Millberg, William Ⓜ Ashtabula, Ohio; Jefferson Medical College of Philadelphia, 1925; member of the American Academy of General Practice and the International College of Surgeons; on the staff of the Ashtabula General Hospital; died in the Jefferson Hospital, Philadelphia, Feb. 1, aged 61.

Mitchell, Samuel Everett Ⓜ Malden, Mo.; St. Louis University School of Medicine, 1906; died Feb. 4, aged 86.

Morrill, Edgar Miner Ⓜ Fort Collins, Colo.; University of Colorado School of Medicine, Denver, 1932; fellow of the American College of Surgeons; for many years a member of the board of education; president of the District 5 Board of Education; veteran of World War II; on the staffs of the Loveland (Colo.) Memorial Hospital and the Larimer County Hospital; died Feb. 3, aged 50.

Morris, Earl Fayette Ⓜ Nevada, Mo.; St. Louis University School of Medicine, 1926; member of the American Psychiatric Association; veteran of World War I; served on the staff at Larned (Kan.) State Hospital and as clinical director at Western State Hospital at Fort Supply, Okla.; clinical director of the State Hospital No. 3; formerly director of health and physical education, Kansas State Teachers' College in Hays, Kan.; died Feb. 4, aged 65.

Nadler, Carl Seepe Jr. Ⓜ New Orleans; Tulane University School of Medicine, New Orleans, 1941; assistant professor of clinical medicine at his alma mater; president of the Louisiana Society of Internal Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War II; on the staffs of the Touro Infirmary, Charity, Eye, Ear, Nose and Throat, and Southern Baptist hospitals; died in Metairie, La., Feb. 5, aged 41.

O'Donnell, Leo Joseph Ⓜ New York City; Cornell University Medical College, New York City, 1927; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; associate clinical professor of obstetrics and gynecology at New York University College of Medicine; served on the staff of the Lenox Hill Hospital; died Feb. 7, aged 57.

Orloff, Henry Samuel Ⓜ Philadelphia; Medico-Chirurgical College of Philadelphia, 1913; member of the draft board during World Wars I and II; on the staff of the Albert Einstein Medical Center, Southern Division; died Feb. 6, aged 76.

Palmer, James Newman Ⓜ New York City; McGill University Faculty of Medicine, Montreal, Que., Canada, 1937; member of the American Psychiatric Association; veteran of World War II; associated with the New York Psychoanalytic Institute; died Dec. 2, aged 47.

Pearson, Leb Elmer, Mangum, Okla.; Memphis (Tenn.) Hospital Medical College, 1904; veteran of World War I; died Jan. 7, aged 79.

Pisani, Adolfo, New York City; Regia Universita di Napoli Facolta di Medicina e Chirurgia, Italy, 1894; served on the staff of the Columbus Hospital; died in the Italian Hospital Feb. 14, aged 86.

Plant, Joseph Henry Ⓜ Los Gatos, Calif.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; retired from the Veterans Administration Oct. 1, 1952; veteran of World War I; died in the Veterans Administration Hospital, Oakland, Feb. 6, aged 76.

Rath, Frieda, Elmhurst, N. Y.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1933; died Dec. 27, aged 50.

Ranck, John Milton Ⓜ Leola, Pa.; Jefferson Medical College of Philadelphia, 1928; a director of the Leola National Bank; died in the Lancaster (Pa.) General Hospital Feb. 4, aged 59.

Schottstaedt, Wilhelm Emil Richard Ⓜ Fresno, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; past-president of the Fresno County Medical Society; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; for two terms president of the city board of education; served as a director of the Fresno County Red Cross Chapter and the Fresno County Tuberculosis Association; on the staffs of the Fresno County General Hospital and St. Agnes Hospital and the board of directors of the Fresno Community Hospital; died Jan. 27, aged 74.

Scott, Raymond Robert Ⓜ Selma, Calif.; Stanford University School of Medicine, San Francisco, 1926; fellow of the American College of Surgeons; veteran of World War II; associated with the Selma Community Hospital; died Dec. 1, aged 59.

Scroggs, William Paxton, Portland, Ore.; St. Louis University School of Medicine, 1908; veteran of World War I; died Dec. 20, aged 76.

Stanford, James Butt Ⓜ Dania, Fla.; born Dec. 17, 1886; College of Physicians and Surgeons, Memphis, Tenn., 1909; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served overseas during World War I; past-president of the Tennessee State Medical Association and the Memphis (Tenn.) and Shelby County Medical Society; formerly practiced in Memphis, Tenn., where he was on the staffs of the Memphis Eye, Ear, Nose and Throat, Baptist Memorial, Methodist, and St. Joseph hospitals; died Jan. 29, aged 72.

Steierman, Charles S. Ⓜ Far Rockaway, N. Y.; Boston University School of Medicine, 1924; associated with St. Joseph's Hospital, where he died Dec. 4, aged 61.

Steuer, David B., Shaker Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1895; also a graduate in pharmacy; formerly city council president; practiced in Cleveland, where he was associated with Mount Sinai Hospital; past-president of the Cleveland Pharmaceutical Association; died Jan. 30, aged 93.

Strader, Simon Ernest, Los Angeles; University of Oklahoma School of Medicine, Oklahoma City, 1917; veteran of World War II; died in the Wadsworth Veterans Administration Hospital Nov. 30, aged 64.

Sullivan, James Albert, St. Louis; St. Louis College of Physicians and Surgeons, 1908; veteran of World War I; died in Hillsboro, Mo., Dec. 21, aged 74.

Thomas, Efton Jewel Ⓜ Miami Beach, Fla.; Northwestern University Medical School, Chicago, 1937; member of the American College of Chest Physicians; served a residency at the Dade County Hospital in Miami; veteran of World War II and was awarded five battle stars during his period of service in France and Germany; on the staff of the James M. Jackson Memorial Hospital in Miami, where he served an internship; affiliated with St. Francis Hospital; died in the Veterans Administration Hospital in Coral Gables, Fla., Feb. 4, aged 46.

Vawter, Fred Loomis, Berryville, Ark.; St. Louis College of Physicians and Surgeons, 1895; died Jan. 11, aged 89.

Wechsler, David, Rego Park, N. Y.; University and Bellevue Hospital Medical College, New York City, 1907; associated with Boulevard Hospital in Astoria and the Physicians Hospital in Jackson Heights, where he died Jan. 11, aged 75.

Wentworth, Harry Wilder, College Place, Wash.; Jefferson Medical College of Philadelphia, 1896; served on the staff of the Nampa State School in Nampa, Idaho; died Jan. 5, aged 89.

Whelchel, Alvin John Ⓜ Cordele, Ga.; Atlanta College of Physicians and Surgeons, 1905; past-president of the Crisp County Medical Society; on the staff of the Crisp County Hospital, where he died Dec. 15, aged 79.

White, J. M., Okmulgee, Okla.; Leonard Medical School, Raleigh, N. C., 1902; died Jan. 24, aged 88.

White, LeMoyne Ⓜ Boston; Harvard Medical School, Boston, 1940; on the staff of the Massachusetts General Hospital, where he served an internship and a residency; certified by the National Board of Medical Examiners; veteran of World War II; member of the American Psychiatric Association; died in the Peter Bent Brigham Hospital Dec. 9, aged 44.

Wilhoit, Fred L., Fort Lauderdale, Fla.; Kentucky University Medical Department, Louisville, 1902; served on the faculty of the University of Louisville (Ky.) School of Medicine; for many years practiced in Louisville, Ky.; died in Fort Lauderdale Beach Hospital Dec. 30, aged 82.

Williams, Lehman William Ⓜ Savannah, Ga.; University of Maryland School of Medicine, Baltimore, 1909; member of the Southeastern Surgical Congress; veteran of World War I; past-president of the Lions Club; died in the Warren A. Candler Hospital Jan. 28, aged 71.

Young, Leslie Winters Ⓜ Fairfield, Ill.; St. Louis University School of Medicine, 1927; member of the American Academy of General Practice; veteran of World War II; past-president of the Wayne County Medical Society; member of the board of health of Fairfield; associated with the Fairfield Memorial Hospital; director of the Fairfield National Bank; died in Port-au-Prince, Haiti Jan. 24, aged 58.

C-Reactive Protein.—At the meeting of the Society of Physicians in Vienna on Feb. 13, Dr. G. Geyer used a rabbit antiserum to precipitate the so-called C-reactive protein (CRP). In agreement with reports in the literature the CRP was observed in the serum obtained from patients who had a high fever, inflammatory and necrotizing processes, or malignant tumors. Its occurrence has been interpreted as a reaction of the plasma-protein system to nonspecific noxa. Consequently, the significance of the CRP for diagnosis is similar to that of the sedimentation rate. CRP was not found in the serum of patients with paraproteinemia, plasmacytoma, and reticulosis, in whom the sedimentation rate was greatly increased. CRP determinations were found useful in evaluating the activity of rheumatic fever. Cortisone causes the rapid disappearance of CRP.

UNITED KINGDOM

Soft Drinks.—New regulations governing the composition, labeling, and advertising of soft drinks are recommended by the Food Standards Committee of the Ministry of Agriculture, Fisheries, and Food. The makers of saccharin strenuously oppose them. They say that replacement of saccharin with sugar would cost up to 8 million dollars and might mean an increase in cost of a penny on a bottle of ready-to-serve and twopence on a bottle of concentrated soft drink. The main recommendations are that all soft drinks containing fruit juice should bear a label stating the percentage of fruit juice in the drink; the use of saccharin should be prohibited except for diabetic drinks, and sugar used instead; the term "glucose" should be forbidden in the labeling and advertising of soft drinks, as well as any form of testimonial or nutritional claim based on the carbohydrate content; and the use of acids for acidifying and flavoring purposes should be restricted and the addition of ascorbic acid allowed, to restore the natural vitamin content, in drinks containing fruit juice.

Student Suicides.—An editorial in the *British Medical Journal* of March 7 comments on a paper published by Sir Alan Rook, from the department of human ecology, Cambridge University, in the same issue. Owing to the complexity of the troubles that lead people to commit suicide, and to the fact that they can usually be investigated only in retrospect, too little is known to take effective preventive action as often as is desirable. This is particularly true of suicides among university students. No apparent difference exists in the incidence of suicide at Cambridge between the decades 1928-1938 and 1948-1958, although a higher rate was found during the intervening 10 years, which included World War II. Student mortality as a whole can be summarized by saying that, of 103 undergraduate deaths in 35 years, 41 were due to accident, 35 to suicide, and only 27 to disease. The figures are similar to those at Oxford.

The combined suicide rate at seven other British universities is much lower than at Oxford and Cambridge, although it is still, so far as can be judged, about twice that for nonuniversity men of similar age in England and Wales. Suicide rates for women students are generally low. Rook showed that few of the ready explanations for the high suicide rate have withstood scrutiny. Ill-fated love affairs, shortage of money, inadequate intelligence, moral perplexity, and the strain of social adjustment that poorer students sometimes experience on arrival at the university have been blamed. No doubt all have figured in individual case histories, but none so far has appeared in more than a small proportion of cases. Among students who become mental patients disharmony between parents and disturbance of relations between the student and members of his family occur oftener than among controls, but M. A. Davidson and co-workers pointed out that over 50% of patients break down in spite of good relationships, and 20% of controls have had similar experiences without breaking down.

Clearly recognizable factors include work difficulties, with the added stress of examinations. Such difficulties may arise from badly organized plans for work, laziness, excessive outside interests, choice of wrong course, illness, or emotional upsets. All experienced counselors know how common is the student who, with an unrealistically high level of aspiration, is encouraged by parental or other pressures to reach for perfection and to regard as failure anything less than first-class honors. The formal diagnosis of depression covers many such situations, not only where reasons for reactive depression are assumed to be the cause but also where absence of any obvious cause earns it the epithet endogenous. Another common factor is the difficulty of finding a

socially acceptable solution to the need for sexual expression. Homosexuality is possibly more commonly associated with suicide than the one case reported from Cambridge might suggest.

Getting Married.—The British Medical Association has stopped issuing its booklet "Getting Married." Dr. Winifred de Kok, who edited the booklet, resigned from the BMA in protest against this action, and so has the author of one of its frankest contributions, Dr. Eustace Chesser. In the booklet Dr. Chesser, a psychologist, discussed whether chastity was outmoded. The BMA action followed condemnation of the publication by physicians and the resignation of several from the association in protest at its contents. Thousands of copies of the booklet on sale throughout the country will not be withdrawn. Of the 250,000 copies printed 200,000 had been issued. The BMA is thus left with 50,000 copies on its hands. These may be released later by the Council.

"All we did," said Dr. de Kok, "was to state the facts given in statistics. We wanted to help all young people, instead of only the good ones." She said she was angry and disgusted by the BMA's action. Dr. Chesser said: "I am amazed that the BMA should have done this. I am at a loss to understand it. Psychologically, I cannot see how the booklet could be harmful to anyone. I feel strongly that medical men, indeed everyone, should have the right to express their views, even though they are not majority views. I fully respect religious views in this matter but the BMA should not have acted on the complaints of a few doctors." Discussing the booklet the *Church Times* says: "There must be many Christian doctors who will loathe and abominate the whole thing. If the BMA wishes to convince the country that there is no longer any connection between medical and Christian morality, it is certainly going the right way about it."

State Scheme for Chiropody.—Chiropody is to be added to the healing facilities available under the National Health Service. Mr. Walker-Smith, Minister of Health, said that he was now ready to approve proposals by local health authorities who wished to provide a chiropody service. Local health authorities will be requested to give priority to the elderly, the physically handicapped, and expectant mothers in the early years of the new service.

Increasing Fertility.—According to a report published by the General Register Office (Fertility Report, Her Majesty's Stationery Office, 1959) the fertility of Britain is increasing. In 1934 the average size of the family had fallen from six, the figure in the 1870's, to two children. With the start of World War II in 1939 there was a steep decline. By 1942 the rate was rising again, and by 1947 the birth rate was at its postwar peak. Since 1952 the fertility rate has been fairly stable. The report reveals that there are about 7,500,000 married women in England and Wales under the age of 50. Among all married women under 50 about 22% are childless, 30% have had one child, 26% two, 12% three, and 10% four or more children. The largest families are found among unskilled workers, where the average size of the family is 2.64 children. The smallest families are those of white collar workers, with 1.49 children, and the professional and managerial class, with 1.51. The area of highest fertility is in Merseyside, near Liverpool, followed by the north of England and north Wales.

Poliomyelitis Vaccine.—A fourth or booster dose of poliomyelitis vaccine for adolescents and adults was recommended by a group of Medical Research Council workers (*Brit. M. J.* 1:609, 1959). This has already been investigated in young children, and the favorable results obtained in this group have now been confirmed in those of older age groups. A booster dose of vaccine was given to 111 adolescents and adults drawn from a population of medical students, research workers, and boys from Epsom College, near London. This was given 6 to 12 months after primary immunization had produced a good response to poliovirus types 2 and 3. All but four of the subjects still had detectable antibody induced by their initial course of vaccination, but with type 1 about a third of those immunized had lost their antibody, and these responded poorly compared with those in whom it was still present. In those who responded poorly to type 1 a fourth dose of vaccine produced a booster response to this type. The MRC workers stated that it was probable that in the age groups studied at least a threefold increase in the amount of type 1 antigen in poliomyelitis vaccine would be necessary to give satisfactory antibody responses after three doses in all subjects.

Budgerigars and Poliomyelitis.—A year ago Sommerville reported that a budgerigar which had nipped the lip of a boy who later died from poliomyelitis had carried poliovirus type 1. He now reports that attempts to infect other budgerigars with the virus were unsuccessful, although the birds became ill between 15 and 21 days after inoculation (*Lancet* 1:495, 1959). A postal survey of 224 families in which there had been a known case of poliomyelitis revealed that 56 kept pet budgerigars and that in 17 instances the birds died at about the same time as a child in the house contracted paralytic or nonparalytic poliomyelitis.

Dick and co-workers of Belfast also investigated the possibility that budgerigars may carry and transmit poliovirus (*Lancet* 1:497, 1959). They found that the birds were resistant to infection with 11 strains given by the oral and intracerebral routes. Poliovirus neutralizing antibody was absent from the blood of 50 budgerigars, and birds were never found with residual paralysis. It was therefore concluded that they do not often become infected with or paralyzed by polioviruses and that they are unlikely to be of importance in the spread of the disease. This does not rule out the possibility that budgerigars may occasionally become infected by people excreting poliovirus and then later transmit the virus to other human contacts. The results of an inquiry into the illness of budgerigars in the household of patients suffering from poliomyelitis yielded surprising results. Of 30 patients who kept budgerigars 3 reported the death of at least one bird within two weeks of the onset of their illness. The authors considered that this was sufficiently suggestive to warrant continued search for an association between human poliomyelitis and poliovirus infection in budgerigars.

Advance in Cardiac Surgery.—An editorial in the *British Medical Journal* of Feb. 28 comments on an operation which was performed by a team under the direction of C. E. Drew in Westminster Hospital on a child, aged 4, who underwent successful repair of ventricular and atrial septal defects, with complete circulatory bypass for 45 minutes. Postoperative recovery was uncomplicated. By incorporating a new technique for cannulating the pulmonary artery, the patient's lungs were used to oxygenate the blood, thus eliminating the machine-oxygenator, which is the main source of serious complications. By means of the purely cardiac bypass so produced it was possible to induce deep hypothermia—below 15 C (59 F)—by extracorporeal cooling of blood flowing from the left atrium. At this low temperature it was possible to shut off completely all circulatory flow during the actual repair of the intracardiac defect. Technical details of the development of the method in dogs were given by G. Keen.

The left femoral artery was exposed, then, after thoracotomy and the administration of heparin, catheters were inserted into the right and left atria and a cannula was placed in the left femoral artery. About 25% of the left arterial flow was drained into a well, pumped through a heat exchanger at 2 to 4 C, and returned to the left femoral artery. The body temperature dropped rapidly. When about 25 C (77 F) was reached the cardiac action became impaired and the circulation fell markedly. At this point a small stab wound was made in the upper part of the right ventricle and a catheter was introduced through the pulmonary valve into the pulmonary artery. The right atrial flow (the whole venous return) was then allowed to drain into a second well, whence it was pumped through the lungs via the pulmonary arterial cannula. The left-sided bypass was fully opened and the rate of the pump was increased. Cooling continued until the body temperature was below 15 C (59 F). The pumps were then turned off and artificial respiration discontinued. The venae cavae were closed by tapes, and the heart was drained. Cardiotomy was then performed and the intracardiac defect repaired. On completion of this the action of the heat exchanger was reversed to warm the blood until normal body temperature was approached.

Germ Warfare.—In February Dr. Barnet Stross asked the Secretary of State for Foreign Affairs to arrange a conference of the great powers to discuss the abolition of stocks of toxins, viruses, and chemicals that might be used in warfare, and the cessation of their manufacture. Mr. Robert Allan, Under Secretary of the Foreign Office, agreed that it would be highly desirable to eliminate this threat, but believed that an agreement to stop making tests of nuclear weapons should be accomplished first. He also told Dr. Stross that the existing international agreements having a bearing on bacteriological or chemical warfare that were enforceable in the United Kingdom were those of the Geneva Protocol of 1925 and the Hague Convention of 1907. Mr. J. Stonehouse asked the Minister of Defense what supplies of botulin were available in this country as part of the defense program and what scientists he had appointed to advise him on the use of this weapon. Mr. Sandys replied that Britain was not developing any such weapon.

Early Operation to Be Telecast.—The question of broadcasting a warning for the benefit of squeamish viewers before a television program about leg amputation in 1846 was considered by the BBC. The program is a documentary entitled "They Made History." A BBC spokesman did not think such a warning would be necessary, as the actual severing of the leg would not be shown, but a short explanatory statement was to be made at the beginning of the program. The scene was to be reconstructed exactly as it was on the afternoon of Monday, Dec. 21, 1846, in the University College Hospital, London, when Robert Liston became the first surgeon in Europe to use ether as an anesthetic. The somewhat primitive operating room was recreated from contemporary descriptions and old photographs. Replicas of apparatus and equipment were specially made for the production from drawings and descriptions in medical journals. An exact copy, complete with straps and straw mattress, of the actual operating table kept in the University College Museum was made, and genuine mid-19th-century surgical instruments were obtained on loan.

CORRESPONDENCE

THERAPY IN BRONCHIAL ASTHMA

To the Editor:—The article entitled "Current Status of Bronchial Asthma," by Segal, in The Journal, March 7, 1959, pages 1063-1071, appears as an authorized publication of the Council on Drugs. Surely such an article must, by inference, contain a distillation of the country's best thinking on the subject. A real responsibility is implied here, because the uncritical reader has no choice but to accept the contents dogmatically. The article does not meet this responsibility. The fundamental fault with this, as with many similar articles not quite as authenticated, is the complexity which they endow on the symptomatic treatment of bronchial asthma. I submit that the principles of treatment are simple and that the real talent lies in discontinuing therapy with numerous and often harmful medicaments and resisting the dangerous temptation to sedate the seriously ill asthmatic patient.

The most fundamental principle in the treatment of bronchial asthma is hydration. The cardinal cause of status asthmaticus is dehydration producing tenacious mucous plugs which can only be removed by fluids in large quantities—orally given in the average asthmatic and intravenously given in the case of status asthmaticus. If the average physician could be impressed with this single fact, the treatment of asthma would be enormously improved. This point is substantially ignored in the article.

I am disturbed also over the rather permissive attitude towards sedatives, especially meperidine (Demerol) hydrochloride. This drug is no different from other opiates in the euphoria it produces and the consequent indifference to cough stimuli. Failure to cough is serious, sometimes fatal, in the asthmatic because of the retained secretions, and I am one of many who have seen a fatal issue laid at the door of meperidine.

I strongly disagree with Dr. Segal, who believes that the "search for the responsible agents is difficult and often completely unsuccessful." He speaks as a specialist in chest disease and is concerned with the lungs. As an allergist I can state with confidence that the responsible agents are usually found when one assesses the total allergic patient and that etiological treatment based on such agents is still the most successful form of treatment known.

Ralph Bookman, M.D.
240 S. La Cienega Blvd.
Beverly Hills, Calif.

To the Editor:—The pertinent questions raised by Dr. Bookman concern hydration, use of meperidine, and the role of the allergist. The introductory remarks in the article, which was reduced in size because of limitations of space, referred to the effects of dehydration in the patient with intractable bronchial asthma. The discussion of the intravenous use of aminophylline described the continuous infusion technique with three liters per 24 hours of a solution of 5% dextrose in water with aminophylline for the hospitalized patient with intractable asthma. This therapy is designed to correct dehydration, supply needed dextrose, and administer aminophylline for bronchodilation. Patients who are receiving iodides are generally urged to take them with 8 to 10 oz. of water or a preferred beverage. I have always used a teaching aphorism that "the value of iodides in the patient with chronic bronchial asthma is proportionately increased by his fluid intake." Patients receiving oral steroids should empirically take 8 to 12 oz. of orange or cranberry juice daily for supplemental potassium and fluid replacement. Correction of dehydration is indeed a very important factor of therapy.

There is a specific place for the use of meperidine in the patient with a severe acute attack or in status asthmaticus when the usual methods of treatment have failed. The value, limitations, and hazards of meperidine usage were clearly stated in the article. In the laboratory we have observed improvement in timed vital capacity and in pressure-flow rate relationships with reduction in the work of breathing in patients with chronic bronchial asthma. In acute studies with patients with the carbon dioxide retention syndrome (severe chronic pulmonary emphysema), we did not observe respiratory depression, increase in arterial carbon dioxide level, or drop in pH. I do not believe that the hazards involved with the judicious use of meperidine are any greater than with the use of a host of other drugs.

Finally, under my discussion of medical management, I stated the importance of allergic factors and the need for specific allergic therapy whenever possible. I believe that it is the opinion of most conservative, competent, and teaching allergists that because the search for responsible agents is frequently difficult and often completely unsuccessful, emphasis on the allergic approach to management should not exclude physiological therapy. A rational, combined approach brings the best results.

MEDICOLEGAL ABSTRACTS

Libel and Slander: Qualified Privilege for Director of Nurses.—This was an action for libel by a private-duty nurse against the defendant hospital and its director of nurses. From a judgment in favor of the defendant the plaintiff appealed to the appellate court of Illinois.

The plaintiff, a registered nurse, was intermittently engaged as a private-duty nurse by various patients of the defendant hospital during the period from August, 1955, through June, 1956. She was a member of the Nurses' Professional Registry. During this period the defendant was the director of nurses at the hospital and was charged with the supervision of all nursing care, including that of private-duty nurses, administered to patients in the hospital. On three different occasions during the months of April and May, 1956, the defendant received reports of narcotics losses from the hospital pharmacist, each report indicating the loss of one 30-cc. vial of Demerol hydrochloride, a narcotic. After the third such report she started checking into the records of the nurses who had been on duty on the floor where the losses occurred. In checking the records of the plaintiff it was found that, on 22 or 23 prior instances, the plaintiff had failed properly to record the administration to patients of narcotics which, from the narcotics record, she had withdrawn from the supply on the floor. On three specific instances it appeared that the plaintiff had failed to record administering Demerol to a patient after having withdrawn the drug from the narcotics cabinet. Normal hospital operating procedures required that the nurse record on the narcotics record the withdrawal of any narcotic, and then record on the individual patient's record, or nurse's record, the administration thereof to the patient. Accurate records and a perpetual inventory of narcotics and the handling thereof are obviously necessary for many reasons, including the doctor's information, the patient's welfare, charting the patient, and inspection by the Federal Bureau of Narcotics. The plaintiff was an experienced nurse and knew the normal operating procedures. The defendant talked to the plaintiff and called some of the above derelictions to the plaintiff's attention, directing that henceforth she should not go into the narcotics cabinet unless another nurse was present.

When the case on which the plaintiff was then working terminated, the defendant called the Nurses' Professional Registry and asked that the plaintiff not be assigned as a private-duty nurse to the defendant hospital in the future. A few days later the Grievance Committee of the registry asked the defendant to put her request in a letter, which she did. This letter is the basis of the present case for libel. The letter stated, in part, that the defendant preferred in the future that the plaintiff not be sent on cases at the defendant hospital. Over a period of the past three months, the letter continued, three vials of Demerol had disappeared from the locked medicine cabinet on the floor where the plaintiff was on duty. In two instances the loss occurred on the 3 to 11 p. m. shift while she was on duty, and the other loss occurred on the 7 a. m. to 3 p. m. shift when she had changed shifts for a few days. Two incidents had occurred the previous winter when the plaintiff charted another medication on her patient's chart but was observed to have taken Demerol. The letter continued that the defendant had talked to the plaintiff about this loss of Demerol and felt that she had a most unusual and abnormal reaction. The letter also stated that the present request in no way reflected on the care given by the plaintiff to patients in the defendant hospital.

This letter was referred by the Nurses' Registry to the Grievance Committee of the Private Duty Section. Copies of the letter were sent to the members of that committee and to the plaintiff, but to no other person.

A privileged communication, said the appellate court, is one which, except for the occasion on which or the circumstances under which it is made, might be defamatory and actionable. We believe under the circumstances that the letter in question was written on a privileged occasion and is qualifiedly or conditionally privileged. Where circumstances exist, or are reasonably believed by the defendant to exist, from which he has an interest or duty, or in good faith believes he has an interest or duty, to make a certain communication to another person having a corresponding interest or duty, and the defendant is so situated that he believes it the discharge of his interest or duty or in the interests of society that he should make the communication, and if he makes the communication in good faith, under those circumstances, believing the communication to be true, even though it may not be true, then the communication is qualifiedly or conditionally privileged, even though the defendant's interest or duty be not necessarily a legal one but only moral or social and imperfect in character. The essential elements are good faith by the defendant, an interest or duty to be upheld, a statement limited in its scope to that purpose, a proper occasion, and publication in a proper manner and to proper parties only. In the absence of actual malice a communication may be qualifiedly privileged, if the other essential elements are present, even though it is not true, and even though it charges a crime;

but a communication loses its character as privileged and is actionable upon proof of actual malice. Both the person by whom and the person to whom the communication is made must have an interest or duty in respect to the matter in order to render it a qualifiedly or conditionally privileged communication. It is clearly settled that a communication respecting the charter of an employee or former employee is qualifiedly privileged if made in good faith by a person having an interest or duty in the premises.

Is the letter itself sufficient competent evidence tending to show actual malice? We think not, said the court. The plaintiff urges that the letter imputes to her the commission of a crime—stealing Demerol from the hospital. We believe it will not fairly bear that construction. It does not say that. "Disappear" does not mean stolen. "Taken" does not mean stolen. And the last paragraph of the letter, stating that this in no way reflects on the care the plaintiff has given patients, is a fair expression of good will, not ill will, and at least is hardly the thing to be expected from a defendant motivated by malice.

There being no competent evidence in the facts and circumstances exclusive of the letter itself, or in the letter itself, tending to show malice, the court of appeals held that the trial court did not err in allowing the defendant's motion for a directed verdict. The judgment for the defendant was, therefore, affirmed. *Judge v. Rockford Memorial Hospital,* 150 N. E. (2) 202 (Ill., 1958).

Governmental Hospitals: Denial of Surgical Privileges.—This was an action for a declaratory judgment to the effect that the plaintiff was entitled to major surgical privileges at the Jackson Memorial Hospital, Miami, Fla. From a judgment in favor of the plaintiff the defendant appealed to the district court of appeals of Florida.

The plaintiff, a licensed physician practicing in Dade County, Florida, applied for major surgical privileges at the Jackson Memorial Hospital in 1952 and again in 1955, but both applications were denied on the ground that he had failed to meet the qualifications and standards set up by the hospital's medical board. The plaintiff contended that such denials were arbitrary, capricious, unlawful, and discriminatory.

Jackson Memorial Hospital is owned and operated by Dade County and the Board of County Commissioners through a medical board responsible to the county commissioners. The hospital is supported by both public funds and paying patients. The bylaws of the medical staff set forth nine requirements for the appointment of a physician to the medical staff, and the defendants contended that the plaintiff did not meet the following requirements: "4. He must be a graduate of an approved medical school. 5. He must have had an internship of at least one year in a hospital approved by the Medical Board. . . . 8. He must be competent in the line of work he proposes to do."

The first question raised on appeal was whether or not a hospital supported by public funds may require of a physician, as a condition to the use of its facilities for major surgery, standards higher than those required by the state for a medical license. In his brief the plaintiff conceded that a public hospital may require higher standards for major surgery than are required for a medical license, but he contended that such rule was not applicable to him. He urged that since the hospital was supported by public funds it could not arbitrarily exclude a licensed physician from the use of such hospital facilities for the physician's own private practice. The court said that the law is well settled that a municipality may regulate and control the operation of a hospital provided by it and that, in the exercise of such power, it may exclude those not shown to have met its requirements. Furthermore, it is not incumbent upon the city to maintain a hospital for the private practice of medicine, nor does a physician have a constitutional or statutory right to practice his profession in the city's hospital. Even though the hospital be a public hospital, the plaintiff as a physician had no right per se to practice in the hospital, it being a privilege rather than a right. In this case, concluded the court, there was no showing that the conditions or requirements laid down by the medical staff for the admission of a physician to staff privileges or for major surgical privileges are unreasonable, discriminatory, or arbitrary, or that they have been so applied to the plaintiff.

The second question urged error in rulings on the facts. The testimony showed that the plaintiff had received a medical degree from a college which had never been accredited and which closed three years after his graduation. Secondly, the testimony showed that the plaintiff interned in a hospital which was not accredited for the purpose of an internship program. Lastly, the testimony disclosed that the surgical experience and skill of the plaintiff fell short of convincing either friends or casual acquaintances that he possessed the requisite qualifications for the exercise of major surgical privileges.

It was the burden of the plaintiff to prove by a preponderance of the evidence that he qualified under the requirements set out and that such requirements were being arbitrarily and discriminatorily applied to him. This, concluded the court, the plaintiff failed to do. The judgment in favor of the plaintiff was, therefore, reversed. *Dade County v. Trombly,* 102 So. (2) 394 (Fla., 1958).

THE LEISURE CORNER

CERAMICS

The making of ceramics is one of the oldest occupations in the world. Ceramic articles dating from as long ago as the Stone Age, 10 to 20 thousand years ago, have been found, and some of them are still in good condition. The crude Indian bowls of North America, the funeral urns of prehistoric China, and the attractive votive goblets of Egypt are among the many historic pieces archeologists have unearthed. In modern times the advance of scientific knowledge has led to new ceramic products and new methods of manufacture.

The word ceramics is derived from the Greek *keramikos*, meaning potter's clay. In a more technical sense ceramics includes all objects, used for practical or ornamental purposes, which are made from clay or mixtures of clay and other substances and baked or fired to hardness; porcelain, earthenware, stoneware, and terra cotta are types of ceramics. The art is determined by the basic charateristics of clay. Clay is plastic; it can be molded or modeled when it is moist. It retains its form when dry, and it becomes rock-hard when exposed to very high temperatures. After it is thoroughly dried or baked it is among the most durable of substances. Clay consists of silica, alumina, and water in chemical combination. Other chemicals, mainly earth oxides, are found in clay and determine its color, plasticity, firing properties, and economic utility.

Modeling by hand is one way of working with clay, hand pressing is another, and a third involves use of the potter's wheel. The basic sequence of steps in making a ceramic article is as follows: (1) constructing the object while the clay is moist; (2) drying the object; (3) first firing; (4) applying the glaze, or underglaze color and glaze; (5) second firing; (6) applying the overglaze color on the glazed object; and (7) applying the overglaze to the object for the third and final firing.

Making small ceramic articles that can be held in the hand appeals to most beginners. Take a chunk of clay, cut it in two against a wire, pound it against a board to release all the air bubbles, and the first step toward creation is taken. A great deal of patience is required to learn how to make pottery. After you have made the model out of clay, having finished it to your own satisfaction, the article must stand for several days until it is thoroughly dry and prepared for firing. After baking and cooling the ceramic object appears dull and a little rough. It must be painted with a glaze before the second firing. Each ingredient of the glaze powder should be measured with care. After this is done the powders are ground with mortar and pestle for about 20 minutes and run through a sieve to remove any lumps, water is added until the mixture is moist, and 4 tablespoons of gum is added. The glaze is then applied to the clay model with a brush.

The story of glazing is itself interesting. The technique of glazing tiles was known in Egypt as long ago as 5500 B. C. In the 18th dynasty, some time between 1540 and 1350 B. C., magnificent glaze colors were in use, notably purple, violet, red, orange, yellow, green, and an almost pure white. These colors were painted on vases and other types of pottery, which remain some of the finest pieces of ceramic art known to man. At present, the introduction of glazes with novel coloring combinations and unprecedented tactile effects occupies the attention and efforts of many ceramic artists, chemists, and engineers. Industrial glazes are applied by dipping, pouring, spraying, or painting. An unfired glaze, when moist, is usually off-gray; consequently, the ceramic hobbist should be aware that in order to establish the appearance presented after the piece is matured in the kiln the glaze must be fired in advance.

The use of the potter's wheel is an ancient technique. The first potter's wheels were probably crude balanced stones, rotated by hand. Various types have been introduced in different countries. The kick wheel is the oldest and simplest form in use today; the seated operator kicks a fly wheel with his foot while manipulating the clay on the throwing head with his hands. The electrically operated wheel, used by professional workers who must turn out a large volume of merchandise, represents a great advance in ceramics. Electric wheels have various attachments for catching clay drippings, for providing water, and for hand rests. The numerous ceramic articles made industrially today play an important role in modern life. Some of these articles, such as fine china, are luxuries, but others, such as firebrick, sewer pipe, and enamel for refrigerators and kitchen utensils, are necessities.

Many doctors enjoy creating ceramic objects as a hobby. Persons who have a definite feeling for clay and an ability to express themselves imaginatively in plastic forms can derive pleasure not only from creating a brand-new ceramic design or making many reproductions of models but also from presenting these as highly personalized gifts to friends and associates. The amateur devotee of ceramics will find that the more he learns about this art the more fascinating he finds it to be. The doctor interested in ceramics discovers that there is "life" in clay and that it can play strange tricks under the influence of "fire." The behavior of color is as capricious as that of human beings. There is no end to the number of articles that can be made for home, office, and personal adornment. Once started, the ceramic hobbyist can find an endless variety of things to create. The most mundane object can be converted to a thing of beauty. Ceramics answers not only the need for self [illegible] also the problem of what to give friends everything.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Functional Colopathy or Irritable Colon with Special Reference to Treatment. E. Gripwall. Nord. med. 61:55-57 (Jan. 8) 1959 (In Swedish) [Stockholm].

During the past year a thorough test of Belladenal Retard, a new sustained-action antispasmodic, was carried out in the medical department of Södertälje Hospital in 35 patients with history of variable psychosomatic disorders of the digestive canal for many years. There were 28 cases of typical irritable colon syndrome, 1 case of duodenal ulcer, 2 cases of gastritis, 1 case of cholelithiasis, and 2 cases of colitis. Most of the patients had previously been treated with the usual antispasmodics. Treatment with Belladenal Retard was given from 1 to 9 months. The side-effects were slight. Approved dietary and hygienic measures were prescribed at the same time. At the end of treatment 17 patients were completely free from symptoms and 15 were improved; 1 patient showed negligible improvement and 2 no improvement. In some cases the improvement continued after withdrawal of the medication.

Systemic Lupus Erythematosus Responding to Chloramphenicol. R. Wells. M. J. Malaya 13:165-170 (Dec.) 1958 [Singapore].

The 2 patients presented were observed in the department of medicine of the General Hospital in Singapore. One was a 30-year-old Chinese housewife, the other a 41-year-old Chinese clerk. The essential complaint was fever of unknown etiology, and examinations of the sternal marrow at the time of admission showed abnormal myelocytes with eccentric nuclei and central zones of pink-staining cytoplasm. These first suggested the diagnosis of disseminated lupus erythematosus, but in the absence of any typical L. E. cells it was not thought justified to treat the patients on that basis. Treatment with chloramphenicol was instituted in the first patient on the basis of an indefinite diagnosis of atypical typhoid. This patient experienced 2 remissions on chloramphenicol therapy. The second patient had one similar remission on chloramphenicol, and it is difficult to believe that the 3 remissions were fortuitous. Investigation failed to show any evidence of concomitant bacterial infections which might have explained the responses to an antibiotic, and it is felt that in both patients the diagnosis of lupus erythematosus explains their illnesses.

When L. E. cells were finally found in the first patient, she was first given cortisone, but later prednisolone was found to be more effective. When the second patient, who had remained well for 3 months after his chloramphenicol-induced remission, was readmitted, he had a typical lupus erythematosus "butterfly" rash over his nose and cheeks and was found to have L. E. cells in his bone marrow and peripheral blood. He responded quickly to prednisolone therapy and has since had no further relapses.

Since observing the atypical myelocytes in these 2 patients, the diagnosis of lupus erythematosus in 2 further cases was first suspected by the chance finding of atypical myelocytes in bone marrow preparations, and in both cases the diagnosis was later proved to be correct. It is possible that the appearance of these atypical myelocytes in the bone marrow in lupus erythematosus may be of diagnostic value at an earlier stage of the disease before the development of typical L. E. cells. Microscopic appearances suggest that these atypical myelocytes do not develop as a result of phagocytosis of erythrocytes and do not represent the typical L. E. phenomenon in myelocytes.

Peptic Ulcer in the Elderly. A. I. Friedman. Am. J. Gastroenterology. 31:15-22 (Jan.) 1959 [New York].

In the 62 patients, over 60 years of age, who received hospital treatment during the years from 1953 to 1956, the diagnosis of peptic ulcer was confirmed by clinical, roentgenologic, and/or pathological evidence. The group included 44 patients with duodenal ulcer, 15 with gastric ulcer, 1 with multiple gastric and duodenal ulcers, and 2 with anastomotic ulcer. The last 2 patients were both men, and in one a recurrence developed after a gastroduodenostomy (Billroth I) and in the other after a gastrojejunostomy (Billroth II). In all, there were 46 men and 16 women. More than half of the patients apparently experienced their first symp-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

toms of peptic ulceration after age 55. Complications were present in 39 of the patients, the most frequent being hemorrhage, which occurred in 29. Perforation occurred in 7, and obstruction in 3 of the patients. The fact that the sex ratio of duodenal to gastric ulcer approached unity in those with acute symptoms is an interesting feature of this age group.

Operations were performed on 10 patients—subtotal gastrectomy (5), gastroenterostomy with vagotomy (2), pyloroplasty (1), and simple closure of a perforation (2). One of the 10 patients died on the 6th day after operation, but, in addition to his bleeding duodenal ulcer, he also had the sequels of a cerebrovascular accident. Thirteen of the patients died while receiving medical treatment, most of them from hemorrhage or perforation. The author feels that this high mortality rate during medical treatment (25%) and the low mortality during elective surgery for ulcer justify a more liberal use of surgical therapy for the complications of peptic ulcer in elderly patients. The peptic ulcer patient over 50, who presents with hemorrhage or perforation, should be subjected to surgical treatment whenever conditions permit.

Bioassay of Urinary Catecholamines in Cases of Pheochromocytomas: Its Diagnostic Value as Compared with Clinical Signs, Roentgenologic Aspects, and Pharmacodynamic Data. L. De Gennes, H. Bricaire and J. Hazard. Presse méd. 67:83-87 (Jan. 17) 1959 (In French) [Paris].

The urinary excretion of catecholamines was studied by bioassay in patients with persistent arterial hypertension or with intermittent paroxysmal hypertension for the diagnosis of pheochromocytoma. The presence of such a tumor was particularly suspected in patients with fluctuations in blood pressure. Among 75 patients on whom the authors have been able to carry out several bioassays of urinary catecholamines, they found 6 cases of pheochromocytoma. Five were discovered at operation, and one at autopsy. In addition to these 6, there were 2 patients in whom the diagnosis was considered probable. The 8 cases are here described. The excretion of catecholamines in micrograms per day was estimated at 360, 1,350, 400, 2,400, 1,000, 180, 275, and 55. In the last 2 patients definitive diagnosis was impossible because no operation was done. The authors consider a daily urinary output of 50 to 55 mcg. of catecholamines normal.

The authors also applied a test with lyophilized Regitine Methanesulfonate, a potent adrenergic blocking agent, which blocks both epinephrine and the effects of sympathetic nerve stimulation. It is emphasized that the drug should be administered by the intravenous route in daily doses of 5 mg. in the adult, and it is effective only if no sedatives were given to the patient 24 hours before the test. A positive hypotensive response consists of a fall greater than 35 mm. H_2O systolic and 25 mm. H_2O diastolic in less than 2 minutes after the injection, and may be then considered theoretically as diagnostic of pheochromocytoma. The test is not dangerous and is easly done; the only side-effects observed were mild discomfort and transitory tachycardia.

Extraperitoneal pneumography combined with urography and tomography was performed on 36 patients, but despite improvements in technique and reading frequent mistakes were made by overestimating the size of the shadows. The clinical study and bioassays of these patients with pheochromocytomas showed that the demonstration of urinary catecholamines is a most reliable and informative diagnostic method which should be conjointly used with pharmacodynamic tests and extrapulmonary pneumography.

Behavior of C-Reactive Protein in Malignant Blood Diseases, with Special Regard to Hodgkin's Lymphogranuloma. V. Pecori, E. Turrisi, P. Altucci and G. Buonanno. Riforma med. 73:1-3 (Jan. 3) 1959 (In Italian) [Naples].

C-reactive protein tests were given to 31 patients, 5 with chronic myeloid leukemia, 3 with chronic lymphatic leukemia, 3 with acute histiocytic leukemia, 1 with lymphoblastic leukemia, 19 with malignant lymphogranuloma (Hodgkin's disease), and 1 with tuberculous lymphadenitis. The patients were between 15 and 55 years of age. The test was performed with a capillary tube, 90 cm. long and 0.4 mm. in diameter, which was filled to one-third of its capacity with C-antiserum and to one-third with the serum to be examined. The tube was then turned repeatedly to mix the 2 serums, and then one of the 2 openings of the tube was sealed with a flame. The first reading was taken after 2 hours of incubation at 37 C temperature; the second reading was taken 12 hours after the first reading, during which time the tube was placed in a refrigerator at 4 C temperature. A 1-mm. column of precipitate was called a 1+ and so on. No precipitation of C-antiserum occurred when serum from normal persons was used. The C-reactive protein test gave positive results in all patients with Hodgkin's disease, and the intensity varied between 3+ and 4+. Most of the patients with high C-reactive protein values presented also high erythrocyte sedimentation values and high diphenylamine reaction values. The 2 patients with Hodgkin's disease whose C-reactive protein test was less than 3+ were passing through at the time of the test a remission of the symptoms; they presented no fever, and the size of the lymph nodes had diminished markedly. High positivity was also noticed in patients with generalized lymphogranuloma. The highest positivity was noted in one patient with multiple lymph node localizations, marked hepatosplenomegaly, and metastases in the cerebrospinal system. Roentgen therapy in patients with localized forms of the disease caused a diminution in the intensity of the test. No therapy had any effect on the intensity of the test in patients with generalized lymphogranuloma. The C-reactive protein test gave positive results in patients with Hodgkin's disease in a very early stage. In some patients highly intensive positive values were obtained by giving the test 1 or 2 days after the occurrence of the first clinical symptoms of the disease. The results of the C-reactive protein test obtained in patients with malignant blood diseases other than Hodgkin's disease were not constant, and the authors found that the test was not of too great importance in such cases. The authors point out the value of the test as a means of determining the course of a specific blood disease. Remission of the symptoms always corresponded with a diminution in the positive values of the test.

SURGERY

Cardiovascular Surgery in a Children's Hospital: I. Acyanotic Lesions: A Review of 241 Operations. R. Ash, J. Johnson, C. E. Koop and others. J. Pediat. 54:133-142 (Feb.) 1959 [St. Louis].

Of 434 cardiovascular operations performed at the Children's Hospital of Philadelphia between 1947 and 1958, 241 were performed on 239 acyanotic children, 6 of whom died, representing an operative death rate of 2.5%. Of the 239 patients operated on, 160 had a patent ductus arteriosus with a continuous murmur. Ligation with 3 silk ligatures was used in 150 of these children. There was no operative death and not a single instance of recanalization of the patent ductus arteriosus. In 10 additional children with patent ductus arteriosus and with pulmonary hypertension, the diagnosis was made, in the absence of a continuous murmur, by an arteriogram in 4 and by cardiac catheterization in 6. There was one operative death, and one patient, in whom pulmonary hypertension persisted postoperatively, died 14 months after the operation. Twelve patients with vascular rings constricting the trachea and esophagus were operated on, with 3 deaths; 2 of the deaths occurred in newborn infants. Thirty-seven operations were performed for coarctation of the aorta, with one death. The authors believe that it is important to operate on patients with coarctation of the aorta during childhood when the arteries are pliable and an anastomosis can almost invariably be performed without the use of grafts. Thirteen patients with atrial septal defects were operated on, and 5 of these had anomalous venous drainage of right pulmonary veins in addition to their septal defects. The surgical intervention was performed under direct vision by means of hypothermia and circulatory occlusion, intermittent when necessary. There were no deaths, and the results were gratifying. Two boys with constrictive pericarditis were operated on, with good results. An arteriovenous fistula involving the left vertebral artery was resected in a 5-year-old boy in whom the site of the fistula had been verified preoperatively by angiocardiography.

Mitral Stenosis Treated by Mitral Commissurotomy: A Medical Review of Surgical Results. E. Gubbay and A. Vineberg. Canad. M. A. J. 80:168-173 (Feb. 1) 1959 [Toronto].

The authors report on 103 consecutive patients with mitral stenosis treated by mitral commissurotomy at the Royal Victoria Hospital in Montreal between 1954 and 1956. Ninety-five of the 103 patients were followed up for at least one year. Of the 95 patients, 67 had pure mitral stenosis, and 28 had mitral stenosis and regurgitation. Of the 67 patients, 39 obtained excellent results, 18 good results, 8 poor results, and 2 died. Of the 28 patients, 5 obtained excellent results, 13 good results, 6 poor results, and 4 died. Of the total number of 6 deaths, 2 were operative deaths, representing an operative mortality rate of 2%. The total number of 6 deaths is not prohibitive in view of the great benefits that may be conferred by the operation. The results obtained and a review of the literature lead to the following conclusions. The operative risk is small and could be reduced further if patients were operated on before they reach the late stages of huge size of the heart, immobile mitral valves, or incompletely controlled heart failure. The results are worth while, even in those with mitral regurgitation, provided that there is sufficient stenosis to relieve and the valve leaflets are mobile.

Segmental Resection for Pulmonary Tuberculosis: An Analysis of 335 Cases. V. O. Björk. J. Thoracic Surg. 37:135-147 (Feb.) 1959 [St. Louis].

The author reports on 335 patients, between the ages of 9 and 64 years, with pulmonary tuberculosis, who underwent segmental resection at the thoracic surgical clinic of the University Hospital in Uppsala, Sweden. The indications for segmental resection were tuberculous cavitation in 314 patients (94%), bronchiectasis with positive sputum in 5, bronchial stenosis in 2, tuberculous empyema with bronchial fistula in 2, and tuberculoma in 12. There were 5 operative deaths (an operative mortality rate of 1.5%) and 7 late deaths. Of the surviving 323 patients, 170 were followed up for periods ranging from 1 to 6 years; 160 (94%) of these were considered cured, since they fulfilled all the following criteria: negative results from guinea-pig tests on gastric washing and sputum, as well as negative cultures on sputum and a negative direct smear on 3 consecutive days, and no active disease found at roentgenologic examination. One hundred forty-six (92%) of the 160 patients were working full time one year after the operation. The best cosmetic result and the best arm movements were obtained when the resection was performed without additional thoracoplasty. Mobilization of the diaphragm gave the best cosmetic but the worst functional result of the various space-diminishing procedures used in addition to segmental resection. Osteoplastic thoracoplasty gave a better cosmetic result and better arm movements when compared with thoracoplasty by rib resection. There was a higher incidence of postoperative pain in the patients on whom thoracoplasty by rib resection was performed. The encouraging late functional results proved that segmental resection can be performed with a minimal loss of function. The contralateral lung withstood the resection very well.

Bronchopulmonary Moniliasis: Treatment by Segmentectomy. J. H. Kennedy. J. Thoracic Surg. 37: 231-235 (Feb.) 1959 [St. Louis].

A 35-year-old man was admitted to Scripps Memorial Hospital in La Jolla, Calif., complaining of *recurrent hemoptysis for 2½ years.* There were no tubercle bacilli in the sputum on cultural examination of 3 specimens, and 3 specimens of sputum of the same unusual character with small black particles in them grew pure cultures of Candida albicans on modified eosin-methylene blue medium. In a roentgenogram of the chest a cavity was observed in the left midlung field; in the lateral view it appeared to lie in the superior segment of the left lower lobe. Thoracotomy was performed through the 5th intercostal space, and the superior segment of the left lower lobe was resected with ligation of the segmental vessels and closure of the segmental bronchus by interrupted sutures. The postoperative course was uneventful.

Gross examination of the operative specimen showed a thick-walled cavitary lesion measuring 3 cm. in maximal diameter. Microscopic examination revealed that this cystic lesion was partially lined with bronchial mucosa showing foci of squamous metaplasia. The cavity communicated with a bronchiole. Most of the cystic area was lined by fibrous tissue, into which there was a marked chronic inflammatory cellular infiltration. The fibrous tissue was covered with a hemorrhagic exudate. Within the cavity of the lesion, definite spore forms with mycelia were detected with periodic acid-Schiff stain. These fungi were consistent with C. albicans.

Four months after the operation the patient felt well and had returned to work, but he noticed a return of small amounts of mucoid sputum, containing small black particles. Culture of the sputum was again positive for C. albicans. The patient then was treated with inhalation therapy in which a bronchodilator and an aerosol of brilliant green dye in a 1 to 200,000 dilution by positive-pressure therapy were used for one month. The patient has now been well for one year, raises no sputum, and has had *no further bleeding episodes;* the small amount of mucoid secretion which he raises from his bronchial tree shows no cultural evidence of fungi. It is believed that this is the second report of successful surgical treatment of bronchopulmonary moniliasis.

Results of Hypophysectomy in the Treatment of Metastatic Mammary Carcinoma. O. H. Pearson and B. S. Ray. Cancer 12:85-92 (Jan.-Feb.) 1959 [Philadelphia].

This report is concerned with 218 patients with metastatic mammary cancer, who were subjected to hypophysectomy by transfrontal craniotomy between March, 1954, and March, 1958. The results obtained in the first group of 109 patients, who had a minimum follow-up of 17 months are presented, but data on the second group of 109 patients are also considered to some extent. The operation was well tolerated, and most patients were ambulatory in 24 to 48 hours. The average period of hospitalization for ambulatory patients was about 10 days. The *hormonal replacement therapy* after the operation consisted of 37.5 mg. of cortisone and 120 mg. of desiccated thyroid by mouth daily. Some patients required posterior pituitary powder by nasal insufflation for control of thirst and polyuria. During periods of stress, the patient usually required increased cortisone replacement. This regimen did not constitute a significant burden for the patient. Contrary to some notions, the patient who has undergone hypophysectomy has a normal appearance and normal mental and physical functions, and he or she can lead a normal life.

The mortality rate from all causes was 7.3%. Although the number of deaths in the second group of 109 patients was the same as that in the first, only one death in the latter group was directly attributable to the operation. Autopsy examination revealed very extensive metastases in the 8 patients of the second group who died postoperatively. Approximately 50% of the first group of 109 patients obtained objective remissions, and 35% had remissions that have lasted 6 months or longer. A prior favorable response to oophorectomy was found to be of prognostic value in predicting a beneficial effect from hypophysectomy. In this group hypophysectomy yielded better results than did adrenalectomy.

Estrogen administration to 5 patients after hypophysectomy failed to induce exacerbation of tumor growth, suggesting that a factor from, or mediated by, the pituitary is necessary for estrogen stimulation of tumor growth. Human growth hormone administered to 5 patients after hypophysectomy appeared to induce stimulation of the tumor growth in 2 patients. These preliminary observations suggest that growth hormone may be an important endocrine factor in mammary cancer. Hypophysectomy is recommended as a practical, worthwhile procedure in the palliative treatment of patients with metastatic breast cancer when adequate facilities are available to carry out this procedure.

Adrenalectomy for Disseminated Mammary Cancer: A Pilot Study of Sixteen Patients. R. C. Hickey. J. Iowa M. Soc. 49:83-87 (Feb.) 1959 [Des Moines].

The author assessed the effects of adrenalectomy on 16 patients with disseminated mammary cancer. The observation period ended in 1958 and covered more than 3 years in some cases; no patient has been followed up less than 6 months. The ages of the patients ranged from 30 to 69 years. No known antitumor therapy was used during the observation period. Oophorectomy was combined with adrenalectomy in most of the 16 patients. In 2 premenopausal patients oophorectomy essentially coincided with the adrenalectomy, and in postmenopausal patients combined oophorectomy and adrenalectomy were performed if a transabdominal adrenalectomy was done. Twenty-four hours preceding the operation the patients were given 50 mg. of cortisone orally every 6 hours, including 5 Gm. of sodium chloride and 2 to 5 mg. of desoxycorticosterone steroid administered by mouth. Two hours before the operation, 150 mg. of cortisone was given intramuscularly. Postoperatively, the regimen of 50 mg. of cortisone given intramuscularly every 4 to 6 hours was continued, supplemented by sodium chloride. The cortisone dosage was dropped gradually in 4 to 6 days to a maintenance dose of 37.5 to 50 mg. of cortisone in daily divided increments along with 3 Gm. of salt. In reducing the postoperative dosage cortisone was given alternately by mouth and intramuscularly to avoid crisis.

In 6 of the 16 patients with mammary cancer, objective improvement occurred with a striking degree of palliation for a mean duration of 12 months or longer. The relief of osseous pain was remarkable; soft-tissue masses regressed, so that palpable lumps became imperceptible and ulcers healed. The longest remission in a patient still doing well has been 38 months, and the shortest period of benefit has been about 6 months. One of the 16 patients experienced subjective improvement for 12 months, which extended her life to 15 months after the operation. Five of the 16 patients showed no improvement; 3 of them died within 2 months, 1 within 6 months, and 1 within 8 months after adrenalectomy. The emotional behavior of 1 of the 16 patients prevented classification of the result. There were 3 surgical deaths among the 16 patients. Death in one patient was caused by ventricular fibrillation and in the other by venous hemorrhage. The third patient died on the 4th day after a stormy postoperative hypoadrenal condition.

The selection of patients for adrenalectomy is partially a trial procedure. A patient must not be to ill for an operative procedure. Retrospective judgment indicates that 2 patients in this study who succumbed were too advanced in their illness to warrant such extensive therapy in the hope of palliation. The author may have erred in carrying out trials of exogenous hormonal administration in lieu of attempting early adrenalectomy in patients who awere failing clinically. It is, however, stressed that adrenalectomy should not be the first strong attempt at palliation. Other means should not be forgotten as one attempts to use or to judge hormonal manipulations or ablations. Focal roentgenologic treatment might well be used advantageously for fractures or osseous destruction, and the bypass of alimentary-tract obstructions may be essential. In judging the effects of adrenalectomy, one must accord other palliative procedures their proper place and merit, and the results of these must not be confused with or mistaken for the beneficial effects of adrenalectomy.

Results of Bilateral Adrenalectomy in the Management of Incurable Breast Cancer: Report of 155 Cases. A. A. Fracchia, A. I. Holleb, J. H. Farrow and others. Cancer 12:58-68 (Jan.-Feb.) 1959 [Philadelphia].

From January, 1951, through June, 1957, 155 patients with breast cancer who were subsequently subjected to adrenalectomy, alone or in combination with oophorectomy, were seen by the breast service of the Memorial Center for Cancer and Allied Diseases in New York. By analyzing the observations on these patients, the authors hoped to clarify further the indications and contraindications for adrenalectomy. It was found that the presence of circulating estrogen, estimated by quantitative analysis of urinary estrogens or by serial vaginal smears, is a valuable criterion for selecting patients for adrenalectomy. When there is no detectable estrogenic activity, ablative surgery is often followed by an unfavorable response, but the existence of estrogenic activity does not necessarily imply success after ablative therapy.

Patients who have benefited from the administration of testosterone or corticosteroids and those who have benefited from castration are more likely to respond favorably to adrenalectomy. The improvement is believed to be due to further suppression of estrogenic activity. Actively menstruating patients who have had a poor response to castration generally fail to derive benefit from adrenalectomy as well. Failure to respond to either androgens or corticosteroids does not preclude a remission with adrenalectomy. The estrogen provocative test is dangerous and not accurate in its predictions.

Adrenalectomy or oophorectomy combined with adrenalectomy produced valuable palliation for 6 months or longer in 54 (34.8%) of 155 patients in this study. This was evidenced by tumor regression with concomitant symptomatic relief and prolongation of life. Patients with inflammatory carcinoma, recurrent involvement of breast, soft tissue, and skin, and bone metastases had the highest percentage of regression, lived the longest, and often were afforded the most satisfactory palliation. The exception in the series with bone metastases was the group of patients with hypercalcemia, none of whom had remissions extending beyond one year.

Although patients with visceral metastases had remissions less frequently and of shorter duration, some did benefit by adrenalectomy. Functional disturbance due to visceral metastases indicated a poor prognosis and usually a poor operative risk. None of the patients with symptomatic preoperative brain metastases from mammary carcinoma benefited from adrenalectomy. Patients (usually menopausal) who underwent oophorectomy and adrenalectomy simultaneously had a higher rate of remission than did those in whom castration was performed first and adrenalectomy later. Hypophysectomy after adrenalectomy seldom produced benefit and is probably not worthwhile.

Intrathoracic Meningocele. H. D. Hilton and H. H. McCarthy. J. Thoracic Surg. 37:261-268 (Feb.) 1959 [St. Louis].

The authors collected from the world literature 27 cases of intrathoracic meningocele in 14 female and 10 male patients, between the ages of 7 weeks and 63 years, and in 3 patients with incomplete data. They also report 2 additional cases of intrathoracic meningocele in a 44-year-old man and in a 37-year-old woman. Fourteen of the 27 patients underwent surgical correction; 4 of the 14 patients died of causes related directly to the operation. The authors' 2 patients underwent myeloplasty and recovered with satisfactory results.

Intrathoracic meningocele is an anomaly usually associated with neurofibromatosis and typical skeletal changes affecting the thoracic vertebrae. The condition may be suspected or even anticipated whenever a posterior mediastinal tumor occurs in conjunction with skeletal changes and neurofibromatosis. Intrathoracic meningocele represents a progressively expanding lesion, subject to rupture, and likely to exert pressure effects on surrounding structures. Consequently, the treatment of choice is surgical repair of the defect.

NEUROLOGY & PSYCHIATRY

The Use of Carbon Dioxide in the Treatment of Postconcussion Syndromes. M. M. Gilbert. J. Florida M. A. 45:891-895 (Feb.) 1959 [Jacksonville].

The author treated 136 patients with a postconcussion syndrome by carbon dioxide–oxygen inhalations. Eighty-four of these patients had had symptoms for less than 6 months before treatment was instituted, and 52 had had symptoms for from 6 to 50 months before the institution of therapy. One hundred per cent carbon dioxide and 100% oxygen in separate tanks were supplied and mixed through a Y-tube so that the concentrations of each gas could be modified. The patients first were given 100% oxygen for a few breaths until they adjusted to the mask and inhalations. Then, about 5% carbon dioxide was added to the mixture to permit the patients to adjust to the odor of the gas. After a few whiffs, the carbon dioxide concentration was increased gradually until there was a 50% oxygen and a 50% carbon dioxide mixture given at about 8 to 10 liters per minute from each tank. This resulted in a profound hyperpnea, and within 10 to 20 inhalations the patients usually lapsed into coma. The masks then were removed, and the patients were allowed to recover spontaneously. Treatments were given 3 to 5 times weekly.

Of the 84 patients, after a median number of 19 treatments, 62 made a complete recovery, and 22 were improved. The complete recovery rate was 74%, and the improvement rate was 100%. Of the 52 patients with long-standing symptoms, after a median number of 22 treatments, 32 completely recovered, 18 were improved, and only 2 were therapeutic failures. They showed a recovery rate of 61%, which compared favorably with the recovery rate of 63% for the group as a whole and with the recovery rate of 74% for the group of patients who had been ill for less than 6 months. Discounting those who discontinued treatment, the over-all improvement rate was 98%. It is presumed that physiological and cellular changes occurred in either the cerebral cortex or the nuclear masses of the brain stem, or in both, as a consequence of brain concussion, these changes resulting in the subjective complaints known as postconcussion syndrome. The concept has been proposed that the carbon dioxide–oxygen inhalations decreased the irritability of the presumably damaged nerve cells by increasing the carbon dioxide tension, increasing the oxygen tension, and increasing the cerebral blood flow. Presumably, correction of the underlying dysfunction and healing occurred. This clinical report might provide a reference and stimulus point for further studies in which more rigid experimental control could be obtained.

Early Experiences with Ultrasonic Irradiation of the Pallidofugal and Nigral Complexes in Hyperkinetic and Hypertonic Disorders. R. Meyers, W. J. Fry, F. J. Fry and others. J. Neurosurg. 16:32-54 (Jan.) 1959 [Springfield, Ill.].

In surgical investigations directed at the basal ganglions to alleviate the hyperkinetic and hypertonic features of parkinsonism, chorea, athetosis, and dystonia, the interruption of the pallidopallidofugal complex was found effective, but the technical difficulty of the operation limited its implementation. The development of a focused multibeam ultrasonic instrument, by means of which lesions of predetermined size, shape, and position could be produced in the brains of animals, offered a safer and more precisely controllable tool for neuroanatomic, neurophysiological, neuropathological, and surgical investigation. This instrument was adapted to human use.

Eleven patients with severe bilateral parkinsonism and one patient with severe bilateral tension athetosis have now been subjected to 15 ultrasonic treatments; 2 received bilateral ultrasonic irradiation, and 1 was treated again on the same side. The procedures were performed while the patients were under local anesthesia. All 9 parkinsonian patients irradiated at the ansa lenticularis alone were relived of rigidity. In 4 of these tremor was simultaneously abolished, and in 2 others it was initially a negligible feature of the clinical picture. Tremor persisted in 3 patients in whom it was subsequently eliminated by irradiation of more caudally situated sites. Within 3 weeks of the ultrasonic treatments, 5 patients exhibited some decrements in the gains realized during the treatments and for the ensuing several days. During the next few months it became evident that the decrements were transient in 3 patients but were enduring in the remaining 2. In view of the early post-treatment decrements and the primarily experimental objectives of the program, irradiation was performed in the 5 most recent treatments at the geometric site (alone) corresponding to portions of the substantia nigra and its immediate superior medial neighborhood. In all cases the first exposure promptly reduced the tremor in at least one and, more often, both contralateral limbs. Rigidity was simultaneously reduced after this first exposure. Further exposures of the "nigral region" counteracted the tremor and abolished or alleviated the rigidity.

With regard to relief of rigidity in parkinsonian patients, a somatotropic differentiation in the "ansal region" was recognizable in at least some patients: a rostrosuperior region corresponds to the contralateral upper limb, and a caudoinferior region to the lower limb. This differentiation was observed more often than not. In addition, a topographic differentiation in the "ansal region" between neural representations of the flexor and extensor muscles of the contralateral limbs was noted in some patients. In some parkinsonian subjects, irradiation fully encompassing the "ansal region" was not followed by reduction of tremor, even though rigidity was abolished in the contralateral limbs. This observation indicates that in such patients tremor is mediated by a different neural mechanism than that subserving rigidity. On the other hand, irradiation of the "nigral region" was always followed by prompt abolition of tremor and simultaneous reduction of rigidity. It may be deduced that the portion of the neural mechanisms subserving tremor and rigidity in the "nigral region" are here closely associated, perhaps even share neural components.

The patient with quadriplegic tension athetosis was irradiated at the "ansal region" on the left side and, 4 months later, at the "nigral region" on the right. The hypertonus was reduced in the contralateral limbs. As to the hyperkinesia, involuntary thrusting movements of the tongue and lips subsided after the left "ansal" irradiation, permitting easy feeding for the first time in years. The athetotic movements in the limbs of the right side were reduced in vigor, amplitude, and frequency and, during repose, were in abeyance. Crude purposive acts could now be executed with the right upper limb. The athetosis of the left-sided limbs was completely abolished after "nigral" irradiation on the right.

DERMATOLOGY

Superficial and Deep Mycoses in Cuba: A Report Based on 1,174 Cases. V. Pardo-Castello and F. Trespalacios. South. M. J. 52:7-15 (Jan.) 1959 [Birmingham, Ala.].

The authors report on 1,174 patients with superficial and deep mycoses, who were observed at the clinic for dermatology of the University Hospital in Havana, Cuba. Of the 1,174 patients, 249 had tinea of the scalp, 227 had tinea cruris, 206 had dermatophytosis of the feet, 144 had onychomycosis, 78 had tinea of the glabrous skin, 71 had chromoblastomycosis, 64 had candidiasis, and 135 had miscellaneous conditions. Tinea of the scalp was most commonly caused by Microsporum canis. One case occurred in a one-month-old infant. The treatment of tinea kerion with penicillin administered locally and systemically was considered most successful. Trichophyton rubrum and T. mentagrophytes were the common agents in dermatophytosis of the feet, with Epidermophyton floccosum next in order. Most cases of onychomycosis were caused by T. rubrum. Treatment with 40% salicylic acid plaster and subsequent administration of antifungal preparations were considered to be the method of choice. In 70 of the 71 patients with deep-seated chromoblastomycosis, Fonsecaea (Hormodendrum) pedrosoi was recovered in cultures. In one case the fungus was identified as Cephalosporium carrionii. Among 135 patients with miscellaneous conditions, there were 10 with sporotrichosis, 7 with actinomycosis, and 6 with mycetoma of the feet. From the latter 6 patients, Nocardia brasiliensis was recovered 3 times, N. pelletieri twice, and Monosporium apiospermum once.

BOOK REVIEWS

Treatment in Internal Medicine. *By* Harold Thomas Hyman, M.D. With foreword by Walter C. Alvarez, M.D. Cloth. $12.50. Pp. 609, with illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5. 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

The writer of the foreword of this volume states, "In this book, I find that Dr. Hyman has again gathered together an amazing amount of information on treatment, and on treatments that have recently been developed." What is amazing is the amount of misleading and wrong information that it contains. In sentences replete with such terms as "anti-infectives," "toxicoderms," "adrenergics," "tuberculocide," "probatory treatment," "antitensives," and "generalist" the reader is told some surprising things. For instance on the first page, apropos of "an integrated program for the care of the infected patient," it is stated that the busy practitioner has neither the time nor the facilities for exhaustive investigation. Hence he is advised to make an "educated guess" on the basis of clinical findings, then "open fire with the particular therapeutic product that appears most apt to decimate the assailant, and least apt to add insult to the defendant's existing injuries. . . . When probatory treatment has proved unrewarding and/or when potential hazards of improvisation appear to exceed possible risks of temporary delay the clinician asks for (1) isolation and identification of the invading pathogen, (2) an estimate of the quality and potency of the patient's antibody responses, and (3) accurate titrations of the particular microbe's sensitivity to available anti-infective agents. With these data at hand he substitutes or inaugurates scientific anti-infective treatment." Many jokes have been concocted over this sequence of events, but never before has such a procedure been seriously advised in a textbook of medicine.

We are advised that penicillin should usually be given orally but if intramuscular use is thought necessary, benzathine penicillin G is the preferred preparation. In the index the reference to subacute bacterial endocarditis directs the reader to hemophilus infections, apparently an error. After some searching a short reference was found to it under a discussion of the "streptococcoses." A 14-day course of daily doses of 6 million units of potassium penicillin G with 2 Gm. of dihydrostreptomycin daily, both intramuscularly, is advised, but no mention of ristocetin is made. On page 22 the reader is advised to "prevent and actively treat staphylococcal, streptococcal and gram negative bacillary super-infections with parenteral streptomycin-dihydrostreptomycin mixtures or with injectable neomycin (3 to 6 mg. per lb. per day)." On page 35, discussing the immediate care of virus pneumonitis, a loading dose of 1 Gm. of "any tetracycline to which the patient has not recently been exposed" is advised. Then the choice of novobiocin, erythromycin, carbomycin, or oleandomycin also is offered. "With failure of response, suspect an error in diagnosis. Collect sputum for microscopy (fungi, acid-fast bacilli) and culture. Obtain blood for culture." And so it goes.

Long lists of proprietary preparations available for treatment are presented with each section of the book. There are many practical hints on the care of the patient in the home which obviously were learned through experience. Because of its many inaccuracies this book cannot, however, be recommended for general use.

Textbook of Surgery. Edited by Guy Blackburn, M.B.E., M.Chir., F.R.C.S., Surgeon, Guy's Hospital, London, and Rex Lawrie, M.D., M.S., F.R.C.S., Surgeon and Assistant Director of Department of Surgery, Guy's Hospital. With foreword by Sir Russell Brock, M.S., F.R.C.S., F.A.C.S., Thoracic Surgeon, Guy's Hospital. Cloth. $16.75. Pp. 1122, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This new textbook of surgery represents an attempt to survey the field of general surgery and the surgical specialties, with the exception of ophthalmology and otolaryngology. The authors state that one of the main objectives was to aid the student preparing for final examinations. Emphasis was, therefore, laid particularly on the clinical side of surgery, and discussion of surgical pathology as well as operative detail was reduced to a bare minimum. The book is well written and the large type is easy to read. The major subdivisions are clearly outlined and there are many excellent illustrations, some of which are in color. It seems unlikely, however, that this book will serve fully the purpose intended for the serious medical student or for the graduate physician. On the one hand it is too long to be merely a synopsis, while on the other it is too short and incomplete to be a well-rounded textbook for the graduate student. It is estimated that those American textbooks which have proved popular contain at least twice the total amount of material presented here. It seems likely, therefore, that this text will find its greatest value as an introduction to a course in surgery for students in the preclinical years, or perhaps as a textbook for nurses.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUESTIONS AND ANSWERS

ANTISTREPTOLYSIN TITER

To the Editor:—*What is the significance of an antistreptolysin titer which remains consistently above 833 units? This occurred in a patient with acute glomerulonephritis in whom all urinary findings were normal for over a year. The sedimentation rate was also normal.*

Glenn T. Howard, M.D., Alice, Texas.

Answer.—Because the upper limit of normal for antistreptolysin titers is considered to be 50 Todd units, it is obvious this patient has an elevated titer. One can only conclude that he has been exposed, or is being exposed, to streptococcic toxin of sufficient antigenic quality and quantity to cause antibody formation. Whether this has been occasioned by the attack of nephritis or by a reaction to some other streptococcic infection cannot be stated, because the titer prior to the attack of nephritis or during the early stages of the disease is not known. It is likely that the present high titer was caused by the disease, but the finding does not now indicate anything more than past or present exposure to antigenic streptococci. This significantly points up the limitations of a single determination of antistreptolysin titer. In the absence of other clinical data to indicate illness in the past year, one may conclude that the present titer is without clinical significance.

SENILE ACHLORHYDRIA

To the Editor:—*In an annual examination program which included the quinine carbacrylic resin test for gastric acidity, about 25% of persons tested were found to have achlorhydria. The patients were of the type usually found in general practice, including many elderly persons. The question arose as to whether a gastrointestinal series should be done on all with achlorhydria. An occult blood test was performed, and this helped in making some decisions.*

Vernon E. Roth, M.D., Marcellus, N. Y.

Answer.—With increasing age, the stomach tends to form less acid, just as the sebaceous glands in the skin form less fat. In 1932, Vanzant and coworkers (*Arch. Int. Med.* 49:345, 1932) studied gastric analyses of 3,746 persons who, after x-ray studies, did not appear to have any organic disease of the digestive tract. They found the incidence of achlorhydria to rise from almost zero in patients at 20 years of age to around 25% in patients at 65. In almost all of these patients the loss of gastric acidity had not produced any symptoms and seemed to need no treatment. The incidence of carcinoma is higher in the atrophic gastric mucosa of persons with primary anemia; hence, these persons should have stomach x-rays at least once a year. However, all persons past the age of 40 ought to have stomach x-rays once a year to be on the safe side. If one waits to do something about cancer of the stomach until it gives symptoms, there will be an even chance that no surgeon will want even to explore the abdomen; if the surgeon does think it worthwhile to explore, there will be an even chance that he will not attempt a resection; and, if he does resect, the chances will be about 70 to 30 that there will be a recurrence. Obviously, the wise person will have the stomach x-rayed at yearly intervals so that if a lesion is found it will probably be operable and resectable.

Answer.—The quinine carbacrylic resin test is valuable in screening for gastric acidity, but it does not reveal a true achlorhydria. This is accomplished by doing a gastric analysis with the use of betazole hydrochloride or histamine. Studies have shown that about 10% of all persons over 65 years of age have achlorhydria after such a potent stimulus. It would be only in these persons that a gastrointestinal series would be definitely indicated.

ACHONDROPLASIA

To the Editor:—*A 24-year-old woman has had three children, the last two of whom died at or shortly after birth with achondroplasia. Because of this condition, which is supposedly transmitted through the male, her husband had a vasectomy last year. The patient wants to have more children. Since she is having great difficulty trying to adopt a child, because of the demand, she is willing to consider artificial insemination, provided she can be reassured she will not have the same results as with her last two pregnancies. Is there any doubt that achondroplasia is always transmitted by the male?*

M.D., Pennsylvania.

Answer.—There is no basis for the belief that achondroplastic dwarfism is transmitted only through the male. It is normally transmitted as a dominant, but, since neither parent shows the defect, it appears probable that it arose as a new mutant—whether in the husband or in the wife it is impossible to say. If it came from the husband,

---

Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

normal offspring would be expected from the proposed artificial insemination. If the mutation was in the wife's ovary, however, she might bear another defective child.

CARBON MONOXIDE POISONING

To the Editor:—*Could the symptoms in the following case be caused by anoxia or methane poisoning? A new space heater had been installed in the living room of the patient's home a few days before this incident. At 1 a.m., a 26-year-old man was found lying in his living room doorway with what first appeared to be a shaking chill. He had vomited and had urinary and fecal incontinence, but he was not unconscious and could answer simple questions. He was pale but not cyanotic. There was no odor of gas in the house (the natural gas used in this area is supposed to have an identifying odor added). The patient was hospitalized, and he felt improved by the time he was admitted but still complained of headache and chilliness. He had had a cold for a few days. A roentgenogram of the chest showed an increase in the bronchovascular pattern. Urinalysis was normal. The hemoglobin level was 9 Gm.%. Babinski's, Chvostek's, and Trousseau's signs were negative. There was no carpopedal spasm. Knee jerks were not obtained. The patient's temperature did not go over 99 F (37.2 C). He was well enough to be discharged at 5 p.m. on the day of admission but could not return to work for a week because of bronchitis and vomiting. Two hours after his admission to the hospital his wife, sister, and two small children in the bedroom were simultaneously seized with headache and vomiting which subsided a few hours after they vacated that apartment. The patient later explained that he had been sitting in the living room watching television while his wife was out and the two children were sleeping in another room. He noted a sharp headache and nausea, but his legs seemed paralyzed and he fell in the doorway as he was telephoning his wife to come home. The space heater had been installed with the warning not to run it continuously before it had been "readjusted," but because of the extremely cold weather it had been burning all day and was not shut off until the other members of the family became ill. Since its removal there has been no further trouble.* *M.D., Massachusetts.*

Answer.—The five patients referred to in this inquiry all suffered from acute carbon monoxide intoxication. The clinical findings in each patient were typical. Some authorities mention that a common finding is a red or cherry red color of the face, but in this consultant's experience pallor is found in about half of the patients with acute intoxication due to carbon monoxide; this is particularly true when vomiting has occurred. The exaggeration of the bronchovascular markings was due to the presence of a respiratory infection and had no relationship to the carbon monoxide poisoning, and the low hemoglobin value seems likewise unrelated. Chemical determination for carbon monoxide in the blood stream made on the husband's admission to the hospital (or shortly thereafter) would have confirmed the diagnosis. Carbon monoxide is one of the most important intoxicants associated with man's life and with the field of industry. It also has an extremely ancient history: its significance began when cave man lit his first fire, and in written records its effects were mentioned by Aristotle in about 300 B. C. and by Seneca in 68 A. D. Today it is a serious economic problem as one of the most subtle and dangerous of the intoxicants in either factory or home life. Natural gas does not contain carbon monoxide and, therefore, cannot cause carbon monoxide intoxication, provided that other gases have not been added to it. On the other hand, various types of manufactured gases and by-product gases may contain 5 to 40% of carbon monoxide; hence, the leakage or escape of such gases can produce carbon monoxide intoxication. Carbon monoxide is formed whenever any organic material is burned with incomplete combustion or too little oxygen. All standard textbooks are full of references to such occurrences with various types of stoves, grates, heaters, braziers, and salamanders. This is precisely what happened in this case, and it is to be noted that warning was given regarding running the space heater continuously and without readjustment. Furthermore, the space heater was not ventilated in any manner, and, presumably, because of the extreme cold, the windows of the rooms were not open. In the monograph by Drinker (Carbon Monoxide Asphyxia, London, Oxford University Press, 1938, pp. 97-103), the composition of natural gas, dangers of heaters, mechanism of the formation of carbon monoxide, and similar subjects are discussed in detail.

ALLERGY TO SILVER PROTEINS

To the Editor:—*What is the danger of an allergic response to topical application of the various types of silver protein solutions?*

Harold A. Abramson, M.D., Cold Spring Harbor, N. J.

Answer.—The danger of an allergic response to topical application of silver protein solutions appears to be remote. The nonallergic reaction of argyria (a grey, blue, slate blue, or brown discoloration of the skin, due to deposition of silver) formerly was fairly common because topical application of silver protein solution to the mucous membranes was frequently continued over long periods, but proved allergic responses to silver protein solutions are exceedingly rare. Howard (*Laryngoscope* 40:215, 1930) reported a patient who developed nasal blockage after he had used a mild silver protein preparation apparently with impunity for several years. The blockage subsided when use of this agent was discontinued. Subsequently, when it was applied again, the patient developed severe urticaria, angioneurotic edema, and collapse. Criep (*J. A. M. A.* 121:421-422 [Feb. 6] 1943) reported a patient who developed sneezing, blockage, rhinorrhea, and wheezing in the course of local treatment with a mild silver protein preparation in the nose and severe asthma when his throat was sprayed with this solution. Scratch tests with a 1% solution of this substance gave positive results, and an intradermal test with this solution was followed by a severe local and mild constitutional reaction. The ophthalmic test also gave positive results. Antibodies were demonstrated in the patient's serum by means of the passive transfer method. Since negative findings were obtained on skin tests with silver nitrate, Criep concluded that the reaction was due to either the protein or the silver protein combination. Additional cases of allergic sensitivity to silver protein solutions may have occurred, but they have not been reported.

COMPOUND TIBIAL FRACTURE

To the Editor:—*One year ago, a patient sustained a multiple-compound fracture of his right leg. In one fracture site, the lower third of the tibia, there is still only a fibrous union in spite of open reduction and approximation of the tibial fragments with a stainless steel screw. What can be done to insure final healing of this fracture? What has been the experience with polyethylene and urethan "glue"?*

S. Perlroth, M.D., New York.

Answer.—Among the important factors that may be related to the nonunion of this fracture are the violence of the trauma which induced the fracture, the initial treatment as related to scene of the accident, the time lapse between injury and definitive treatment in the hospital, the primary method of immobilization and its duration with or without changes for improvement of position or angulation, the relationship of internal fixation to date of injury, the duration of external fixation and non-weight-bearing after fixation of fragments with the screw, the patient's present state of health, his emotional reaction to his problem, and his blood chemistry. If a fibrous union is now said to prevail, it is important to know when and how the basis for this statement was established. Knowing this, together with consideration of the above factors, one might confidently conclude that the patient has a delayed union rather than a nonunion. Continued immobilization is indicated. No surgical procedure should be considered to insure final healing until the state of nonunion has been established on the basis of all reliable criteria, including a liberal consideration for the criteria of time. Fractures of the distal third of the tibia are noted for the frequency of delayed union and; less frequently, nonunion. For this reason, it is wise to be guided by the laws which govern the healing of fractures instead of rushing into surgical treatment. If the indications for an operation should be established in this instance, the transplantation of cancellous iliac bone to the fracture site should be considered. There are too many unanswered questions regarding the use of polyethylene and urethan glue to warrant their use. These should not be added to the complications which are known to prevail in this case.

COLONIC POLYPS

To the Editor:—*A 42-year-old man was operated on for polyps of the colon and rectum. A resection of the sigmoid was performed. Two polyps showed early malignant changes. There was no invasion of the serosa, and the mesenteric lymph nodes were free of metastases. What are the chances for complete and permanent cure? Inasmuch as this patient has a tendency to develop colonic polyps, what can he do in the future to avoid them? What is the role of protein foods and, in particular, dairy products in the development or prevention of these polyps?*

M.D., Illinois.

Answer.—The chances for complete and permanent cure are excellent. This consultant knows of nothing that can be done to prevent future polypoid formation, but a proctoscopic examination should be made annually without fail. A colon x-ray examination with use of the air contrast technique should be made every two or three years. If new polyps are detected proctoscopically, an x-ray examination of the colon should be made at once and the newly discovered polyps fulgurated or removed without delay. There are no drugs or special diet which would prevent recurrence. Protein and dairy foods do not play any role in the development of polyps.

THROMBOANGIITIS OBLITERANS

To the Editor:—*Are there any detectable signs in the oral mucosa which might hint at latent thromboangiitis obliterans? Are these signs influenced by recent smoking?*

Richard L. Westerman, M.D., Gunnison, Colo.

Answer.—This consultant is unaware of any vascular lesion in the oral mucosa suggestive of thromboangiitis obliterans. It is true that this disease may occur in many visceral vessels, including cardiac, renal, and cerebral arteries. While many systemic disorders have characteristic signs in the oral cavity, thromboangiitis obliterans is not one of them.

Law Admitting Aliens with TB Approved . .
Prescription Abuse Crackdown Planned . .

RADIATION FALL-OUT HEARINGS OPEN

Scientists offered lawmakers sharply differing opinions on the danger of radioactive fall-out from nuclear tests as a House-Senate atomic energy subcommittee opened an intensive investigation of the controversy.

The dispute broiled over into the international field as a U. S. Commission on Radiation Protection and the International Commission on Radiological Protection went in opposite directions in revising maximum permissible levels of radiation for the general population. The international group lowered the standards, while the National Committee on Radiation Protection and Measurements hiked the danger levels.

About the only real agreement seemed to be that the radioactive matter deposited into the atmosphere by nuclear tests does not do any good and probably does some harm. But how much was the question.

Underlying the entire issue is the contention by some members of the Atomic Energy Committee that the Atomic Energy Commission is minimizing the dangers to the public because of what it believes to be the overriding necessity of continuing atom and hydrogen bomb tests to keep the United States militarily prepared. This has been flatly denied by AEC officials.

AEC Chairman John A. McCone disclosed that the commission's General Advisory Committee would soon "give further assurance to the people of the world about the very small hazard resulting from fallout." He said the danger now is not serious when compared with natural sources of radiation such as x-rays. Continued unrestricted testing, though, could lead to serious danger, he declared.

Pointing up the scientific confusion, Dr. Charles L. Dunham of the AEC's Division of Biology and Medicine told the House-Senate subcommittee at its opening hearing that fall-out "might" cause 50 to 100 additional bone cancer cases a year for the next 70 years and 100 to 200 extra cases of leukemia annually. However, he said these were estimates based on one current theory, and "there may be no additional cases at all."

Rep. Chet Holifield (D., Calif.), chairman of the subcommittee, expressed concern at AEC figures on the amount of radioactive debris that has been deposited by the U. S., Great Britain, and Russia. He noted that the 40,000 kiloton total (21,000 kilotons by the Soviet Union; 19,000 by the Western powers) in 1957 and 1958 far exceed a safety limit of 10,000 kilotons annually that was set by a group of scientists at the subcommittee's previous hearings on the subject in 1957.

E. A. Martell of the Air Force's Cambridge Research Center testified that the 30-year exposure to dangerous radioactive matter in the northern hemisphere would be more than 10 times what AEC officials have estimated.

SENATE GROUP APPROVES INTERNATIONAL RESEARCH BILL

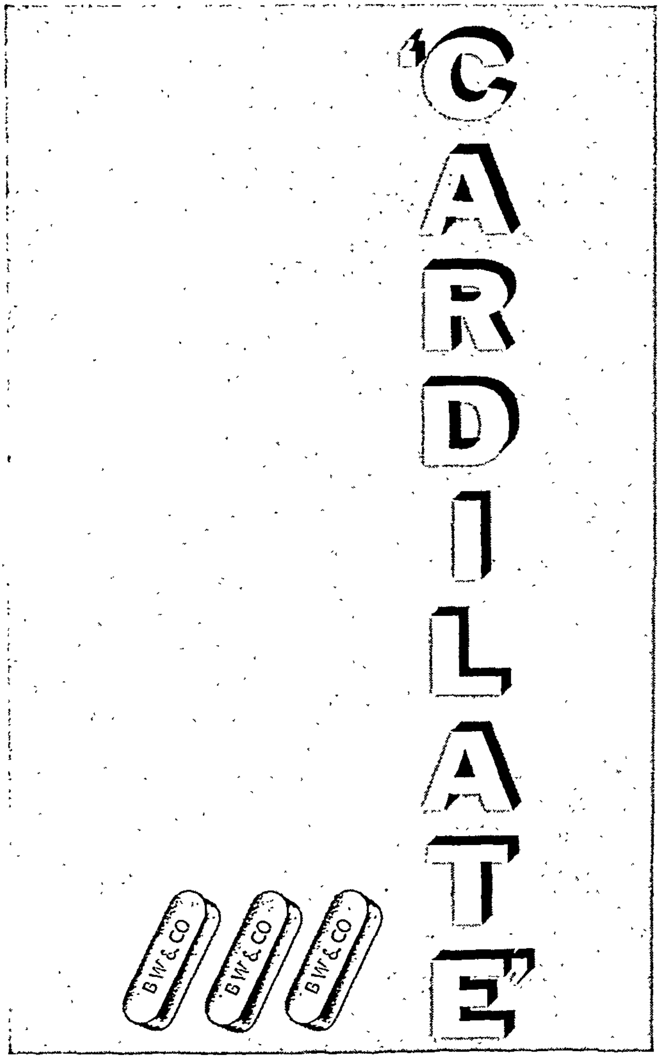
The Senate Labor and Public Welfare Committee, as expected, approved a 50-million-dollar annual program to expand international health and medical research. The program, endorsed by the American Medical Association, would come under the U. S. surgeon general and be run as part of the National Institutes of Health.

A new National Institute for International Medical Research would be established under the measure that is backed by 59 senators. Though the administration objected to some features of the measure, including the flat 50-million-dollar annual authorization, the widespread support among the lawmakers appeared to assure easy congressional passage this session.

FLEMMING ASKS SENATE TO HOLD LINE ON HEW SPENDING

Arthur S. Flemming, secretary of Health, Education, and Welfare, has carried over to the Senate his fight to keep the HEW budget down to the size proposed by the administration.

(Continued on next page)



'CARDILATE'
sublingual tablets for angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

Tuckahoe, N. Y.

Testifying before a Senate appropriations subcommittee headed by Sen. Lister Hill (D., Ala.) he declared that "if the Federal Government does not act to strengthen the economy, combat inflation, and assure fiscal stability, we will end up by spending more dollars to buy less."

However, Senator Hill, who also is chairman of the full Labor and Public Welfare Committee, remarked that he thought the House in approving increased funds had "followed an awful good precedent." He noted that his subcommittee had increased money for HEW for the past six years.

The National Institutes of Health would receive 50 million dollars more than the $292,700,000 requested under the appropriations measure okeyed by the House. All of the new money would go for medical research and training. Several hundred new employees could be hired.

The measure grants the Food and Drug administration 2 million dollars more than the budget request, bringing the agency's appropriations for the fiscal year starting July 1 to a record total of $13,800,000.

Many private physicians spoke in support of higher medical research outlays in testimony before the House appropriations subcommittee that first considered the money bill. One of the witnesses, Dr. Stewart H. Clifford, assistant clinical professor of pediatrics, Harvard Medical School, had this to say:

"I think the problem boils down to what is morally and ethically right and what is wrong. I believe that to go to the American people and tell them that in order to make what has been said to be a fraction of a percent saving in the budget you have been forced to curtail research projects that may be of tremendous value to the citizens would boomerang on those that advised such false economy."

HEW Secretary Flemming, in his Senate testimony, declared it was difficult to see how research would be impaired under the administration's program, noting that the total requested was the same as approved by Congress last year in a big increase over the administration's 1958 request. Furthermore, he said, some of last year's appropriation will not be spent this fiscal year.

In other testimony before the Senate appropriations subcommittee, U. S. Surgeon General Leroy E. Burney asserted there is a shortage of trained personnel in all health fields, including research.

HOUSE VOTES EXTENSION OF LAW ADMITTING ALIENS WITH TB

The House passed and sent to the Senate legislation continuing for two years, until June 30, 1961, authority to admit aliens afflicted with tuberculosis into the United States provided rigid medical supervision is afforded.

The measure, aimed in large part at permitting Korean orphans to come to this country to adopted parents, requires that sponsors file affidavits stating that financial arrangements for the aliens' care have been made with a hospital. Assurance also has to be given that the alien will go to a hospital immediately on admission.

As of the end of last March, 1,567 persons had been admitted under the law. The A. M. A. has urged stricter medical standards than were provided previously.

FDA PLANS LEGAL MOVE ON P. R. N. ABUSES

A Food and Drug Administration official said the agency is making plans to bring a court case against any pharmacist who commits "flagrant violations" in refilling p. r. n. prescriptions.

Nevis Cook of FDA's enforcement division said *present law needs to be clarified and that a court* suit might settle the issue. Some pharmacists, he said, have been using no discretion in refilling prescriptions for sleeping pills, amphetamines, and other drugs that can be misused. The legal issue is whether indiscriminate refilling of this type of prescription by pharmacists constitutes an improper assumption of the practice of medicine, according to the official who urged physicians to use care in making out "Refill as Occasion Requires" prescriptions.

INSURANCE INDUSTRY VIEWS ON HEALTH COVERAGE FOR U. S. WORKERS

A spokesman for the nation's life insurance companies told congress that a deductible feature in any health insurance plan for federal civilian workers would "result in a much more economical and efficient health care program."

Manton Eddy, speaking for the Health Insurance Association of America and the Life Insurance Association of America, told a Senate labor and public welfare subcommittee that the organizations warmly endorse such insurance for government employees.

A deductible provision under which employees would pay a certain amount of the cost before they are compensated by the insurance company "will operate to remove the substantial administrative burden of handling a very large number of claims for *minor illnesses*," he *said*.

The administration recommended deductibility also. The subcommittee headed by Sen. Richard M. Neuberger (D., Ore.), is considering various proposals to cover federal workers.

'CARDILATE'
sublingual tablets for angina pectoris

"Nitroglycerin and erythrol tetranitrate when administered sublingually are among the most effective of all prophylactic agents available for the treatment of patients with angina pectoris. The comparatively prolonged duration of action of erythrol tetranitrate makes it especially valuable for clinical use."

Riseman, J. E. F., *et al.*: Circulation *17*:22, 1958

EFFECT OF A PRACTICAL DIETARY REGIMEN ON SERUM CHOLESTEROL LEVEL

Philip A. Boyer Jr., M.D., James T. Lowe, Ph.D., Robert W. Gardier, Ph.D.
and
John D. Ralston, M.D., Indianapolis

THE medical literature over the past few years contains a wealth of material on the role of diet in relation to health and disease, particularly atherosclerosis, and a number of excellent reviews[1] have appeared. Data have been accumulated from many countries of the world, encompassing three principal disciplines: epidemiologic, experimental, and clinical. With few exceptions, the evidence points to a significant correlation between diet, hypercholesteremia, atherosclerosis, and coronary heart disease. Intensive research efforts are being directed toward gaining a better understanding of the nature of these relationships and the many factors known to influence them directly or indirectly.

The urgency of the undertaking is manifested by the fact that heart disease continues to be the number one cause of death in the United States and that the rate appears to be increasing rather than decreasing. Equally disturbing is the fact that atherosclerosis, the forerunner of coronary artery disease in 97% of the cases, is no longer solely a disease of the aged. Autopsy studies on soldiers with an average age of 22 years, who were killed in the Korean war, showed atherosclerosis to be present in 77% of the cases.[2] "Among adults in the United States, at least, the question is not who has atherosclerosis, but rather who has more and who has less."[3]

The fact that experimentally produced atheromatous plaques are reversible lesions suggests the possibility of benefit from diets tending to lower the blood cholesterol levels. The effects of a diet of this sort were studied in 300 institutionalized patients under conditions permitting rigorous control. The significant feature was the use of a margarine containing 64.2% of nonhydrogenated corn oil. The kitchen staff prepared the same dishes as before with few modifications, and the transitions from contratest to test diet went unnoticed by the majority of patients and by many members of the staff. In a nine-month study it was shown that this dietary alteration raised the percentage of linoleic acid in the diet about 300% and significantly reduced the blood cholesterol levels in a manner acceptable both to the patients and to the staff.

While the exact relationship between hypercholesteremia, atherosclerosis, and coronary heart disease still remains to be determined, evidence is

---

From the Research Division of the Pitman-Moore Company and the Central State Hospital.

steadily accumulating on the desirability of reducing cholesterol levels in those patients where they are elevated. The Framingham studies [4] have shown that persons with high cholesterol levels suffer a far greater risk of coronary heart disease than those with low levels. In this study of over 1,000 men, aged 45 to 62 years, covering a four-year span, the incidence of coronary heart disease varied from a low of 15 per thousand at one end of the scale, to a high of 295 per thousand at the other end. The three main factors implicated in the development of coronary disease were elevated serum cholesterol levels, high blood pressure, and excess weight. Data from such studies show that it is possible to quantitate the risk of coronary heart disease by evaluating these factors along with other pertinent information from the patient's history. The ability to classify a patient as a high coronary risk in an actuarial sense permits the timely application of appropriate prophylactic or therapeutic measures. With respect to the factors incriminated in these studies, blood pressure can now be controlled within limits, obesity can be corrected, and hypercholesteremia can be reduced.

Studies on the production of experimental atherosclerosis in animals have also yielded valuable information on the nature of this disease. It has been shown that within limits the atheromatous plaques are reversible lesions. Thus, arterial atheromas in rabbits, chickens, and dogs have been found to undergo gradual regression when the hypercholesteremia was corrected through dietary manipulation. In studies on human tissue cultures of aortic cell, the deposition of cholesterol has been accelerated by the inclusion of a saturated fatty acid (stearic) in the medium and has been inhibited by the inclusion of an unsaturated fatty acid (linolenic).[5] Numerous cases of regression of cutaneous xanthomas in persons placed on low-fat diets have been reported.[6] It seems clear that cholesterol deposits in at least some tissues can be resorbed in the human.

In 1952 Kinsell and co-workers [7] showed that the ingestion of diets rich in vegetable oils produced a fall in blood cholesterol levels and this observation was subsequently confirmed by other investigators. Later work showed that it was the essential unsaturated fatty acids in the diet which exerted the cholesterol-lowering effect, while the saturated fatty acids exerted a cholesterol-raising effect. These findings have given rise to a wholly new concept in the formulation of special dietary regimens, stressing the importance of the unsaturated versus the saturated fatty acid content. As information on amounts of these factors present in different foods has become available,[8] the therapeutic dietitian has received new tools with which to devise palatable, interesting, and effective blood cholesterol-lowering diets.

While direct clinical proof of the value of reducing elevated cholesterol levels is not yet available, supporting evidence in favor of such a step continues to accumulate. Morrison [9] has found that the use of dietary regimens designed to decrease blood cholesterol levels is followed by definite improvement in patients with angina pectoris or myocardial infarction, and Kinsell and co-workers [10] have seen functional improvement in patients with peripheral vascular disease which can be associated with reduced cholesterol levels.

Dietary supplements in the form of safflower oil, corn oil, and vegetable oil cocktails have recently been employed as means to reduce serum cholesterol levels with varying degrees of success. However, when used in effective amounts, the additional caloric intake presents real problems in weight control. The exchange of one fat isocalorically in the diet for another would obviate this difficulty. Since the removal of saturated fat from the diet has been shown to be more effective in reducing blood cholesterol levels than the addition of unsaturated fat,[11] the most expedient approach would appear to be the replacement of a regular article of diet rich in saturated fats with one rich in unsaturated fats.

Method

A corn oil margarine rich in essential unsaturated fatty acids was developed as a substitute for the ordinary solid fats in the diet, including those used for cooking [12] as well as those used for a spread. The margarine contains 64.2% nonhydrogenated corn oil and 15.9% of hardened fats. It contains 44.5% of linoleic acid calculated on the basis of total fat.

The effectiveness of a dietary regimen in lowering blood cholesterol levels in which this corn oil margarine replaced other solid fats in the diet was studied over a period of nine months. The work was carried out at the Farm Colony of Indiana's Central State Hospital where ideal conditions existed for the complete and rigorous dietary control of over 300 institutionalized patients. Subjects were ordinary psychotics free from any major organic disorder and included men and women in the ratio of approximately four to one. The average age of the patients, both men and women, was 60 years. The average weight of the men was 149 lb. (67.6 kg.); of the women, 136 lb. (61.7 kg.).

The diet kitchen was under the supervision and control of a graduate dietitian who prepared the menus and rotated them on a weekly basis. Dishes varied considerably from day to day but the over-all menu from week to week remained essentially constant. Meals were carefully planned so as to be nutritious, palatable, well balanced, and adequate for a population engaged in moderate physical activity. The same food was served the staff as the patients, and the meals were uniformly referred to as being good. The control diet was simply a continuation of the regular diet in which butter, hydrogenated fats, and vegetable oils were customarily used either on the table or in the kitchen. The treatment diet was essentially the same, except that corn oil margarine was substituted routinely for these solid fats and was used as a table spread as well as for all cooking, baking, and frying, and, when melted, as a seasoning agent for vegetables. In the preparation of salad dressings and in other places where a liquid oil was desired, corn oil was used exclusively. The kitchen staff prepared exactly the same dishes as previously, serving the same kind and cuts of meat as before. Excess visible fat was removed, however, and bacon drippings were discarded. Reconstituted skim milk was substituted for whole milk, whether used as a beverage or in cooking, and sherbet was substituted for the ice cream served twice weekly. Aside from these changes, every effort was made to maintain the same basic diet during the treatment period as during the control period. Weekly menus for the control period and the treatment period were analyzed statistically for total calories, calories from fat, and calories from linoleic acid. The figures were calculated from the food supplied the kitchen, rather than the food consumed. No effort was made to measure the actual food intake during the study.

Serum cholesterol levels were determined at periodic intervals during the initial control period of three weeks, the treatment period of five months, and the post-treatment (control) period of three months. The analytical method used was a modification of the Schoenheimer-Sperry technique. A total of 301 patients were included in the study, although the number available for blood samples on any one occasion varied from 277 to 298. Determinations of serum cholesterol level were made 11 times over the course of the study for a total of 3,177 individual analyses—each done in duplicate.

Body weights were recorded at five different times during the study; once on the control diet, three times on the treatment diet, and once on the post-treatment (control) diet.

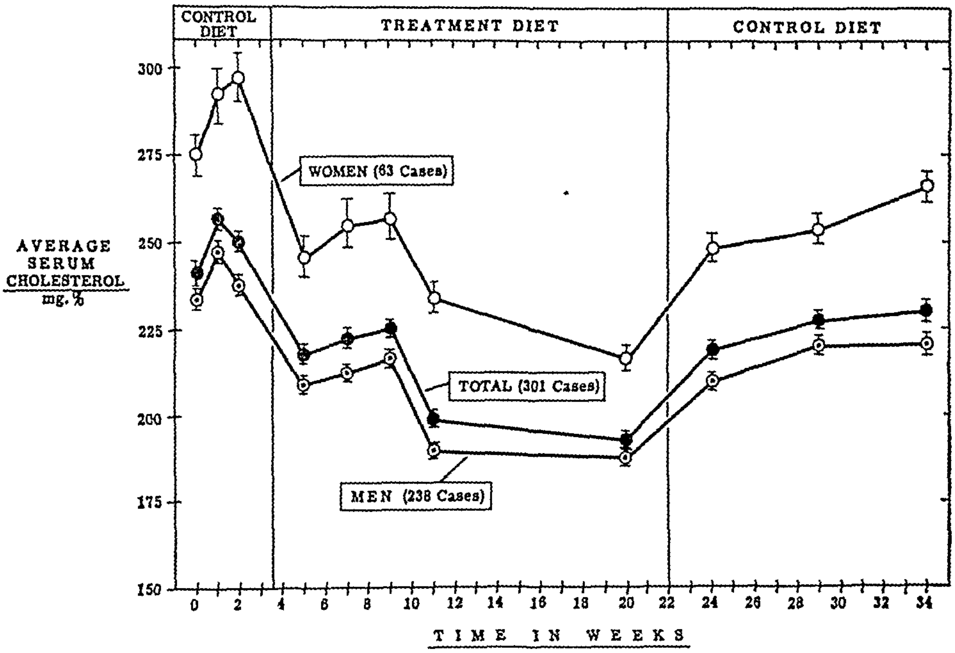

Fig. 1.—Effect of practical dietary regimen on serum cholesterol levels in 301 patients.

Results

The curves showing the variations in serum cholesterol levels for the 238 men, the 63 women, and the 301 men and women, averaged together over the three different periods of study, are presented in figure 1. It will be seen that the curves for the men and the women run remarkably parallel. The higher values for the women are in accord with reports from other investigators for this age bracket.[13] A 13% drop in serum cholesterol levels occurred for the combined groups within three weeks after the inauguration of the test diet, from 250 to 218 mg.%. The drop was accentuated as the treatment continued, reaching a maximum fall of 23% after five months on the diet, from 250 to 193 mg.%. When the control diet was reinstituted, serum cholesterol levels rose 19% over a three-month period, from 193 to 230 mg.%. These data are for the men and women grouped together. An examination of the weights for both men and women during the five different weighing periods showed that the maximum change for either sex between any two periods was less than 1 kg. (2.2 lb.).

The data on cholesterol values were also analyzed in relation to three other factors, namely, age, weight, and control cholesterol levels for both men and women, as shown in figure 2. The comparison was made between the average of the three cholesterol levels during the control period with the average of the first three levels during the treatment period. The line of demarcation for any category was arbitrarily established at that point which would permit an equal number of cases to be above and below a given value. In the case of age, the dividing line was

60 years for both men and women. In the case of weight it was 149 lb. for men and 136 lb. for women. In the case of the control cholesterol level, it was 237 mg.% for men and 288 mg.% for women. A statistical evaluation of the cholesterol values for groups stratified on this basis showed no significant effect on the percentage change in average values resulting from the diet. Thus, age, weight, and control cholesterol levels were without effect under these conditions.

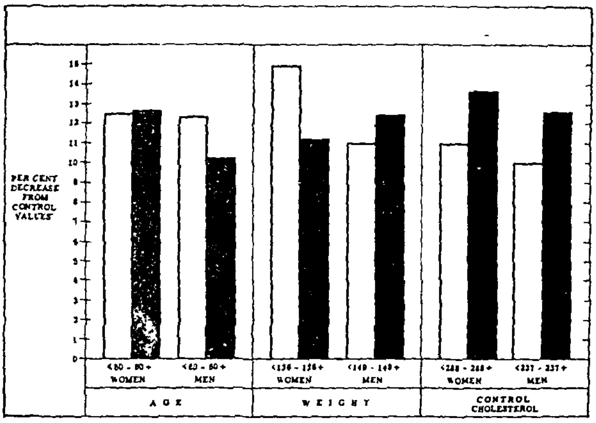

Fig. 2.—Effect of age, weight, and control cholesterol levels on percentage change in average values resulting from diet.

An analysis of the control and treatment diet in regard to total fats, calories from fat, and calories from linoleic acid is presented in figure 3. Values were computed on the basis of food supplied the kitchen rather than on actual food consumption and, therefore, are only approximate. Total calories for a week on the control diet amounted to 15,500; on the treatment diet 14,600. Total fat amounted to 828 Gm. per week on the control diet and 700 Gm. per week on the treatment diet, representing 48% and 43%, respectively, of the total calories. The linoleic acid content amounted to 60 Gm. per week on the control diet and 153 Gm. per week on the treatment diet, representing 7% and 22%, respectively, of the fat calories. The percentage of linoleic acid in the fat of the treatment diet was thus triple the percentage of linoleic acid in the fat of the control diet.

Comment

The treatment diet followed in these studies was unique in that it represented no conspicuous departure from the general food pattern to which the patients were accustomed. It allowed them to continue enjoying meals as they had always known them, without the need for acquiring new "tastes" for different dishes or for old familiar dishes prepared in a bland or unappetizing fashion. The treatment diet corresponded so closely to the regular diet that the transition went unnoticed by the majority of the patients including many members of the staff.

The study was designed to be conducted at a practical level in order to determine what results might be expected under normal operating conditions. No effort was made to influence the patients' voluntary intake of food at any time. The food consumption was virtually the same during the control and the treatment period, and there were no significant changes in body weight during the course of the study. Comparison of the percentage of calories from fat in the two diets showed a 5% lower level in the treatment diet. This can be accounted for largely by the use of skim milk in place of whole milk and of sherbet in place of ice cream. The influence of these minor dietary alterations in reducing serum cholesterol levels is considered relatively unimportant in this instance, since another study[14] in which these variables were excluded produced essentially the same response. The significant feature is that the percentage of linoleic acid in the diet was effectively raised about 300% without disturbing the basic dietary pattern or without the addition of added calories—thus offering no problems in patient acceptability or in weight control. While an institution provided the type of control group needed for a large scale study under standardized conditions, the findings would appear to be directly applicable to home use.

	CONTROL DIET	TEST DIET
TOTAL FAT	828 Gms.	700 Gms.
CALORIES AS FAT	48%	43%
LINOLEIC ACID	60 Gms.	153 Gms.
FAT CALORIES AS LINOLEIC	7%	22%

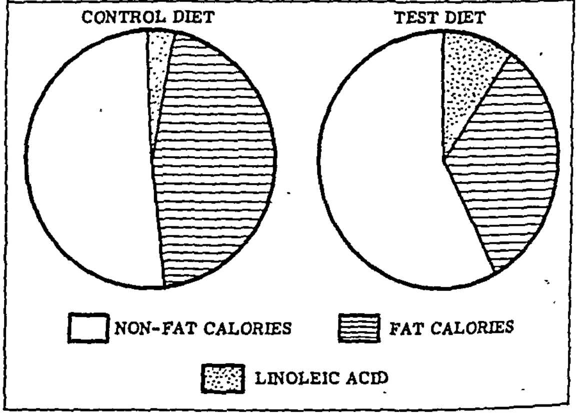

Fig. 3.—Amount of fat and linoleic acid in weekly diets.

Summary

In a nine-month study of over 300 inpatients in a state institution, it was found that a regimen employing a nonhydrogenated corn oil margarine for other solid fats as the principal dietary alteration was effective in achieving and maintaining a reduction in blood cholesterol levels. The dietary alteration was accomplished simply, easily, and inconspicuously, and with an excellent degree of patient acceptability.

P. O. Box 1656 (6) (Dr. Boyer).

Dr. C. L. Williams, Superintendent of Central State Hospital, provided facilities for this study.

The corn oil margarine used in this study was supplied as Emdee margarine by Pitman-Moore Company, Indianapolis.

AIR HYGIENE FOR HOSPITALS

II. EFFICIENCY OF FIBROUS FILTERS AGAINST STAPHYLOCOCCIC DROPLET NUCLEI AND BACTERIA-BEARING DUST

Henry F. Allen, M.D., Boston

A laboratory and operating room study shows that it is possible to provide absolute filtration of bacteria on dust particles and high retention of bacterial droplet nuclei through installation of certain deep-bed glass-fiber material in the hospital ventilating system. A glass-asbestos paper offered retention in the same range. No hospital should accept an installation which has not been found to retain at least 85% of atmospheric dust or its equivalent. Careful performance testing of the installation is essential.

There is general agreement that air supplied to delivery rooms, operating rooms, and nurseries should be free from dust and bacteria. On the one hand, pure air is needed to maintain dilution of airborne contaminants derived from human sources inside these areas; on the other hand, the demonstrated fact that pathogenic organisms may enter such spaces via air-conditioning ducts[1] must be guarded against by efficient cleaning of air supply.

To insure satisfactory performance over long periods, devices for delivering clean air should be simple and trouble-free and should require a minimum of maintenance.[2] Recent developments in the field of air filtration permit realization of these objectives at reasonable installation expense and low operational costs. This paper reports studies of the arrest of bacteria-bearing particles by fibrous filters in experimental and actual situations.

Bacteria in air occur as droplet nuclei or are attached to minute particles of dust, lint, or skin. The former are produced by the atomization of re-

---

From the bacteriology laboratory, Massachusetts Eye and Ear Infirmary, and the Department of Ophthalmology, Harvard Medical School.

spiratory secretions, as during talking, laughing, coughing, or sneezing. These droplets approximate 10μ in diameter and evaporate almost instantly in air of a relative humidity of less than 100%.[3] The droplet nuclei which remain after evaporation consist of one or more bacteria with a coating of dried organic material. They are usually between 1.34 and 2.68μ in diameter[4] and settle at an average rate of 0.04 ft. per minute in still air. As convection currents tend to keep room air in constant motion, bacterial droplet nuclei tend to remain in a state of continuous suspension.

Bacteria-bearing dust particles are thought to vary greatly in size and to be much larger than droplet nuclei. Most of them settle at 1 or 2 ft. per minute in still air,[5] but some may be continuously suspended in moving air.

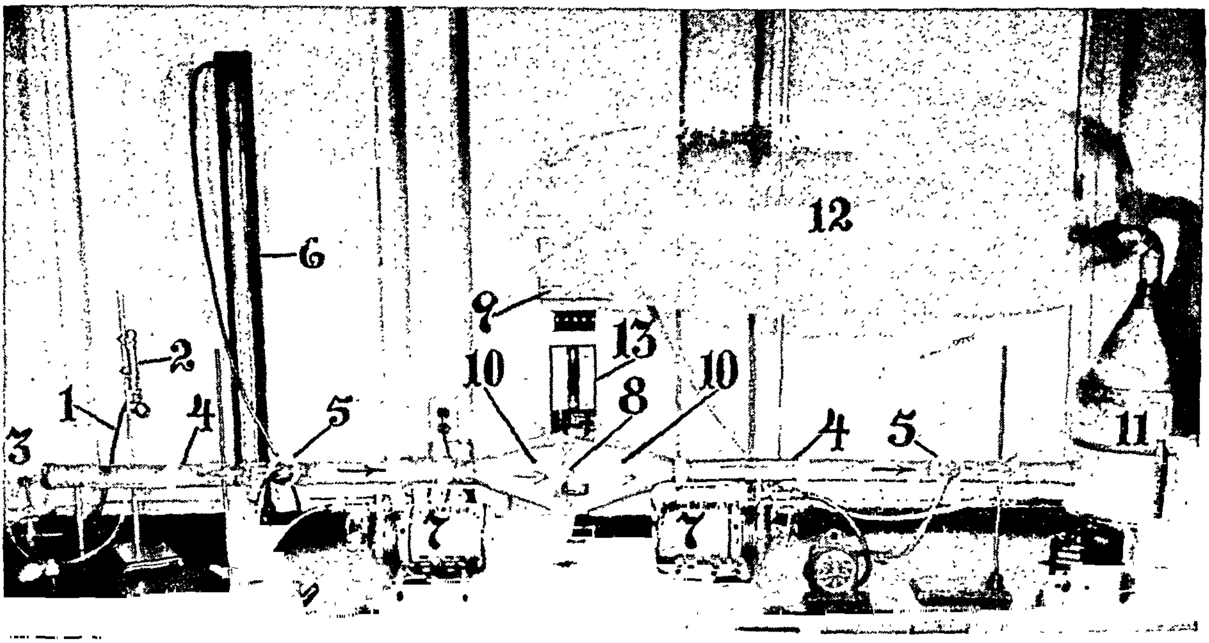

Fig. 1.—Filter-blower system: 1, nitrogen supply line; 2, flow regulator; 3, DeVilbiss 40 nebulizer; 4, location of dispersion disk; 5, sampling point (MF holder); 6, mercury manometer; 7, vacuum pumps; 8, filter medium in holder; 9, water gauge manometer; 10, filter holder; 11, fan; 12, calibrated bag (not used during tests); 13, wet and dry bulb thermometers.

Ventilating air is cleaned by passage through devices which operate on one of the following principles: (1) impingement on mediums coated with viscous material, (2) impaction on fine fibers of dry porous mediums, (3) electrostatic precipitation, or (4) washing or scrubbing by passage through wet cells or fine sprays.[6]

The antibacterial efficiency of viscous and wet cell filters is too low to warrant their use in critical hospital areas. Electronic air cleaners have been reported[7] to possess high efficiency against airborne bacteria and viruses but will not be discussed in this paper. Fibrous filters may be made of fabric-like mediums of wool felt or cotton batting or cloth; deep-bed mats composed of glass fibers averaging between 0.8 and 3.0μ in diameter, which may be bonded together by phenolic resins; or papers of cellulose and asbestos, glass, glass and asbestos, or ceramic fibers with or without a binder. A great increase in filtering surface can be achieved by pleating these materials. Air velocities through the medium usually range from 5 to 25 ft. per minute. In general, units presenting a superficial area of 4 sq. ft. provide an air flow of 1,000 cu. ft. per minute at an average duct velocity of 250 ft. per minute. Retention of particles by these mediums is largely the result of inertial impaction of particles on fibers. In addition, the static gas film around fibers may interfere with the passage of particles.

Although physicians do not ordinarily carry out performance tests on air filters, an understanding of the basis for efficiency rating is important. This is because a filter which is highly efficient against particles 10μ in diameter may be extremely inefficient against particles 1μ in diameter. A case in point is the poor performance of viscous filters against atmospheric dust.

Deep-bed mats composed of glass fibers averaging between 0.8 and 3.0μ in diameter are rated by the National Bureau of Standards (NBS) discoloration test with atmospheric dust used as the test material; that is, against particles averaging 0.5μ in diameter. Their efficiency increases with the useful life of the filter as particles build up on the filter face. Efficiencies from 35 to 95% over the life of different grades of filters are achieved at the rated velocity. The initial resistances of the various mediums range from 0.14 to 0.48 in. water gauge at the rated velocity.

Paper filters are rated by the NBS discoloration test or in terms of their efficiency against dioctyl phthalate (DOP) smoke, an aerosol of particles uniformly 0.3μ in diameter. Absolute filters achieve a minimum guaranteed arrest of 99.95% against DOP smoke. Their retention of bacteria approaches 100%. This high efficiency is obtained at the cost of increased resistance to air flow.

Experimental Studies

There are few studies of the efficiency of fibrous mediums against micro-organisms. Decker and coworkers[8] tested the efficiency of three grades of glass-fiber pads and of two types of mineral papers against freshly atomized aerosols of Serratia indica and Escherichia coli T-3 bacteriophage. A single-thickness pad possessing the characteristics of Filterdown 50-FG retained 99% of the bacteria and 98% of the bacteriophage. Penetration of the glass-asbestos paper was 2.8 to 14 per 10 million organisms; of type E glass paper, 1 to 2 per 100 million organisms.

§ At rated velocity.

Because the bacterial species used by these workers is particularly vulnerable to drying,[9] and because neither it nor the bacteriophage is likely to be encountered in environmental air, it seemed desirable to confirm these studies and to extend them to a pathogenic species more resistant to drying, to bacteria attached to dust particles, and to other filter materials. At the same time an opportunity was afforded to compare two sampling techniques in the light of newer knowledge regarding one of them.[10] With these purposes in mind the following test situation was established.

Materials.—A filter-blower system was adapted for bacterial sampling of air upstream and downstream from the filter medium. The assembly (fig. 1) consisted of several feet of round, galvanized, sheet metal duct 2 in. in diameter, a filter holder composed of two four-sided funnels with flanges by means of which the funnels could be clamped base to base, and a fan at the downstream end of the system. The filtration surface was 6.5 in. on a side, with an area of 0.29 sq. ft.

The downstream section of the filter holder incorporated a fine, stiff stainless steel screen to provide backing for the filter medium being tested. The screen was spot-soldered to the flange, and the interstices of the meshwork were filled with aluminum powder in a plastic base so as to present a flush, smooth border 1.25 in. wide around the periphery of the filtering surface. A gasket of spun glass fiber was cemented to the downstream flange and one of 0.12-in. foam rubber to the upstream flange. Clamps were used to maintain firm pressure through the opposed flanges on the filter medium between the gaskets.

The ducts were equipped with dispersion disks located five duct diameters upstream from each sampling point to provide thorough mixing of the aerosol before sampling. The sampling points were located 20 in. downstream from the intake and from the filter holder respectively. All joints were made airtight with sealing tape.

Air samples were taken through right-angle glass tubes, 6 to 8 mm. in diameter, inserted through the duct wall and pointing upstream in the center of the duct. The air was sampled for bacterial content either by filtration through cellulose ester gel membranes (Millipore filters [MF]) or by bubbling through critical orifice liquid impingers containing 200 cc. of 3.2% brain-heart infusion with 0.2% gelatin solution,[10] the stem being 4 cm. from the bottom of the container. The pH of the impinger fluid was 7.2. A loopful of a silicon antifoaming agent (Antifoam A) was added to each impinger. Sampling rates were 2.0 to 4.5 liters per minute, a pressure drop of 24 in. Hg being maintained across the critical orifices during operation. The dimensions of the sampling tubes were selected to make the sampling velocity approximately isokinetic with the central duct velocity.

Fresh aerosols were produced by atomization of bacterial suspensions from a DeVilbiss 40 nebulizer activated by nitrogen from a commercial cylinder at a flow rate of 6.4 liters per minute; 12-to-24-hour broth cultures of Staphylococcus aureus (Food and Drug Administration strain 209, American Type Culture Collection 6538) were diluted with sterile distilled water to a degree suitable for sampling after nebulization. The organisms were less than 1μ in diameter and were highly dispersed.[11]

Dry aerosols were produced by insufflating fine dust obtained from the filter cones of ward vacuum cleaners into the duct from a powder blower. These dust-coated cones retain almost 100% of airborne bacteria contacting them.[11] The principal species recovered from this dust were represented by strains of yellow and white staphylococci, hay bacilli, sarcinae, and assorted molds. It is probable that the bacterial particles were not in a state of high dispersion in these aerosols.

The properties of the several filter materials tested are shown in table 1. At least three samples from one or more lots of each medium were tested, and at least three trials were made with each sample.

Operation.—The humidity of the room air was adjusted to the desired level by allowing steam to flow from the chamber of an autoclave into the room. The rate of air flow through the system was adjusted by controlling the fan speed to produce the desired velocity at the filter face. Flow rates were measured directly by timing the inflation of a calibrated bag of light-weight polyethylene, capacity 5.5 cu. ft. (fig. 1).

Millipore filter	257	3.4	98.68
Impinger	920	9.4	98.98
Impinger: Millipore filter	3.57	2.75	

* Temperature 23 C, relative humidity 34%.
† Sampling rate, 2 liters per minute.

With air flowing through the system at the desired rate, fresh or dry aerosols were introduced at the intake and allowed to flow for from 1 to 30 minutes before sampling was begun. Sampling was carried on simultaneously at the upstream and downstream sampling points, usually for 60 seconds.

At the end of each run, the filter membranes were transferred to the surface of trypticase soy agar plate or aliquots of the impinger fluid were filtered through Millipore filters (HA type) which were incubated on the same solid medium. After incubation of the plates at 37 C for 24 hours and 22 C for 12 hours colonies were counted under magnification, using the ophthalmic biomicroscope and slit lamp (Zeiss Opton).

Conditions and Controls.—The temperature during these experiments varied from 21 to 24 C; the relative humidity was adjusted between 31 and 71%. The construction of the system insured that no room air was drawn into it or the samplers other than that which was introduced at the intake. Organisms present in the room air were not of the test species and were numerically insignificant in proportion to those in the artificial aerosols, and their occasional presence appeared to have no effect on the results.

In a representative number of trials, but not in all, the filters and the downstream sections of the filter holder and ducts were sterilized by hot air between tests. Failure to sterilize them in other trials appeared to make no difference in the results of these tests, presumably because the test organisms were not present on, or were not liberated by blow-off from, the filter pads or the interior surfaces of the ducts in significant quantities. The sampling membranes were sterilized by autoclaving.

The experimental techniques used in this study are described more fully in the first paper of this series.[11] At the relatively low filtration velocities and the relatively small sampling volumes used in the present study there was no evidence that variation of the relative humidity within the range recorded above had any effect on either the efficiency of filtration by the glass-fiber materials or the recovery of organisms on the sampling membranes (MF). In contrast to conditions in the former study [11] there was no warming or drying of air during its passage through the filter-blower system. Humidification of sampled air by passing it through 18-in. by ¾-in. tubes containing rolled moist filter paper failed to increase the yield of organisms on the MF in comparative tests with air of 39% relative humidity at a sampling rate of 2 liters per minute.

There was no evidence of increasing penetration of the fibrous materials with time. Rather, it was clear that accumulation of dust on the filters increased their retention of bacteria. Filterless trials indicated an expected recovery rate of 90% or better at the downstream sampling point. No correction for this factor was made in calculating efficiency of filtration.

Results.—The findings recorded in table 1 refer to retention of bacterial droplet nuclei by new, unused filter materials in terms of the dry (aerosol assay) Millipore filter sampling technique. When parallel sampling by this method and by liquid impingers operated at an identical rate (2 liters per minute) was conducted simultaneously at both the upstream and the downstream sampling points, impinger counts were 3.3 to 3.57 times those on the MF at the upstream point and 2.75 to 2.9 times those on the MF at the downstream point. In spite of the threefold disparity in absolute values filtration by the glass-fiber medium demonstrated by both methods was of the same order of efficiency. It is presumed that the larger number of organisms recorded by the impinger represents both break-up of bacterial aggregates by it and decay of organisms after contacting the MF surface. The former factor could account for the slightly higher efficiencies demonstrated by the impinger technique, since aggregates which would produce only a single colony on the MF would presumably be arrested by the glass-fiber filters more readily than single cells. The fact that the efficiency of the more retentive materials appeared nearly the same by both methods is consistent with monodispersion of the particles in the aerosol. A typical trial is shown in table 2.

Of the deep-bed materials, clean single-thickness pads of Filterdown 50-FG ordinarily retained 98.5 to 98.7% of freshly nebulized bacterial aerosols. Impinger samples confirmed the 99% retention reported by Decker and his group for the same medium. However, one substandard lot was received which passed up to 15% of droplet nuclei. This was returned to the manufacturer, who confirmed the poor performance of the sample and stated that steps had been taken to prevent release of substandard lots in the future. Single-thickness pads of Aerosolve 95, a deep-bed medium of considerably lower resistance to air flow than Filterdown 50-FG, showed an average retention of 95% with a range from 89 to 98.5% in different runs. Retention of droplet nuclei by dust-laden filters was higher than by clean filters. Both mediums retained essentially 100% of bacteria-bearing dust particles produced by the powder blower. It is reasonable to assume that any medium retaining 90% or more of an aerosol of droplet nuclei would retain essentially 100% of bacteria attached to atmospheric dust particles.

Unlike absolute filters deep-bed filters are not individually guaranteed as to their efficiency by the manufacturer. This fact suggests the need for testing the performance of individual filters used in critical situations, especially in view of the variation we have observed in different lots of deep-bed material.

Penetration of the glass and glass-asbestos papers by droplet nuclei was roughly in proportion to their DOP ratings. The high retention of these mediums was achieved only at a resistance to air flow significantly greater than that offered by the deep-bed mediums. A cotton surgical face mask retained less than 20% of staphylococcic droplet nuclei.

Field Studies

Because of abnormally high bacterial counts in the operating rooms, a survey of the two operating suites was undertaken. With use of titanium tetrachloride as an indicator it was determined that air from the corridor was being drawn into each of the four eye operating rooms and exhausted through ceiling ports in the scrub rooms and anesthesia rooms. When the doors to the corridor were closed a brisk flow of air under them into the operating rooms was apparent. The air flow at either end of the main corridor of the operating suite was then tested, and it was found that air was being drawn under and between the double doors which opened into the main stair well of the hospital at one end of the corridor and into the ear, nose, and throat outpatient clinic at the other. A similar situation was encountered in the ear, nose, and throat operating suite on the floor above.

A survey by ventilating engineers confirmed these findings. It was brought out that the air-supply fans had been slowed in order to reduce the intake of outdoor dust through viscous panel filters. At the same time exhaust fans in the anterooms continued to operate at their original speed, so that a negative air pressure was created in the operating rooms. The parallel between this situation and that reported by Blowers and co-workers[12] is striking.

In accordance with the consultants' recommendations the exhaust ports were sealed off and fan speeds increased to the maximum, 1,700 revolutions per minute, creating a positive pressure in the operating rooms. Air escaped by exfiltration under doors and through louvers into surrounding areas. The total air flow thus provided was between 500 and 600 cu. ft. per minute for each operating room, with 100% outside air, providing about 12 air changes per hour. Viscous filter panels in the intake ducts for outside air were supplemented by banks of deep-bed glass-fiber filters (Aerosolve 95) in the distribution ducts to each operating room.

TABLE 3.—*Performance of New Filters to Operating Rooms Against Nebulized Staphylococci**

Room	Colonies per Cu. Ft.		Efficiency, %
	Upstream	Downstream	
1	5,400	160	97
2	3,600	170	95
3	2,400	170	93
4	8,000	228	97

* Pressure drop: 0.24-in. water gauge; 15-min. trials at 2 liters per minute.

In order to test the efficiency of the completed installations, samples were taken from the ducts at suitable locations upstream and downstream from the banks of filters while freshly nebulized and dry dust aerosols were being introduced through openings in the duct wall into the air stream from the supply air fan. The first tests showed penetration of the order of 50%. The fault was traced to defective installation and token calking of the cadmium-plated filter frames in the ducts and to omission of the tie-rods used to seat the filter cartridges firmly against the felt gaskets in the frame. This omission was contrary to the manufacturer's specifications. In one instance the metal-tapping screws used to fasten the water gauge manometer to the duct wall had forced the filter frame inward away from the duct. After correction of these deficiencies, retention of the order of 95% was found for droplet nuclei (table 3). The effect of ventilation on the concentration of droplet nuclei (Staph. albus) nebulized into an operating room is shown in figure 2.

Comment

Selection of a filter for a given purpose represents a compromise between high efficiency and low pressure drop (inversely reflecting power cost) and service life.[13] For air supplied to hospital operating rooms, delivery rooms, and nurseries, this compromise must be resolved in terms of the expected microbiological and particulate challenge to the filter and the efficiency of cleaning required of the filter against the expected challenge.

The state of bacteria and molds in outside atmospheric air is not entirely clear. Colebrook and Cawston[14] found a preponderance of nonpathogenic bacteria and molds with occasional colonies of Staph. aureus in air sampled on the roof of their hospital. There was no way of telling whether these organisms were free-floating or attached to dust particles. The infrequency of the common human respiratory pathogens in their samples suggested that few bacteria existing as droplet nuclei survive drying and exposure to atmospheric conditions out of doors.

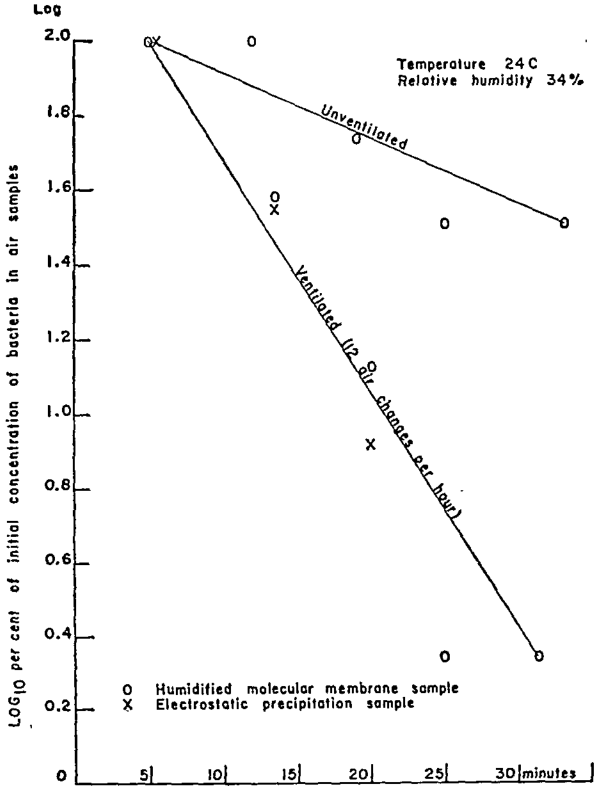

Fig. 2.—Rate of disappearance of Staphylococcus albus from ventilated and unventilated rooms.

The efficiency of the deep-bed mediums Filterdown 50-FG and Aerosolve 95, together with a high rate of flow at a low pressure drop across the filters, renders them acceptable for filtration of ordinary atmospheric air supplied to critical hospital areas. The high pressure drop across the absolute and semiabsolute mediums would make their use appear uneconomical for air supplied to spaces in which human beings are continuously liberating organisms from their persons.

No filter medium can be better than the tightness of its installation. As air seeks the path of least resistance, the volume of air bypassing a loosely installed filter bank will increase with the build-up of dust in the filter bed. At the same time, low manometer readings may give the erroneous impression that the filter bed is operating well below its maximum permissible pressure drop, when actually the reverse is the case.

Unlike a plumbing installation a faulty air filter assembly shows no immediate sign of leakage. Because the load of particles entering the air intake during any short period of time is small, dust and bacteria may accumulate before spilling over into a channel. If alternate moisture and drying exist at an upstream location, bacteria which have proliferated during the moist phase may strike the filter face en masse during the dry phase. Detection of leakage would thus depend on prolonged sampling, fortuitous sampling during a period of spillage, or performance tests using a standard challenge of dust or bacteria.

Neither the contractor nor the consulting engineer carried out a performance test of the filters installed in the ducts leading to our operating rooms. Moreover, the consultant failed to detect the contractor's failure to meet the manufacturer's specifications for installing the filters. No hospital should accept an installation which has not been found to retain at least 85% of atmospheric dust or its equivalent. Ventilating engineers should be prepared to certify the initial performance of any high-efficiency filter system and to spot-check any sample of fibrous medium for substandard efficiency.

A correctly installed bank of deep-bed glass-fiber filters protected by suitable viscous or electronic prefilters requires remarkably little maintenance. After six months of continuous (24-hour) operation, the pressure drop across the filters for our operating rooms had risen from 0.25 to 0.42 in. of water (maximum allowable dirty drop is 0.8 in. of water). Other advantages include disposability, ease of replacement, and retention of dust during filter changes. Heavy particles on the duct floor should be removed by vacuum cleaning at the time of filter changes.

The ceramic paper is intended for high-temperature dust filtration and would not normally find an application in hospital ventilating systems. The absolute mediums, because of their higher resistance to flow, are not ordinarily used in air supply systems for hospitals.

The glass-asbestos paper (Micretain) is stated by the manufacturer to be suitable for use in supply systems to operating rooms. A cartridge presents 200 sq. ft. of pleated filtering surface and permits an air flow of 1,000 cu. ft. per minute at a clean rated pressure drop of 0.4 in. water gauge. Because of its higher efficiency, greater uniformity, and longer service life (4,000 hours with adequate prefiltration) the manufacturer believes that this will be an economical filter for critical hospital air supply situations.

The excellent retention rate of several fibrous filters suggests the desirability of designing ventilating systems to permit partial recirculation of air. The advantages of recirculation in permitting easier and cheaper control of temperature and humidity are obvious, especially where explosive vapors are not in use. Even when volatile agents are being used Thomas[15] feels that the present requirement of 100% outside air is unreasonable and that 50% recirculation would be perfectly safe at the same relative humidity.

In ordinary ventilating situations the need to sterilize fibrous filters in place does not arise. If it became necessary to sterilize a heavily contaminated exhaust filter this could be done with beta-propiolactone in the vapor phase[16] or with ethylene oxide in suitable combination with an inert gas.

The high efficiency of Filterdown 50-FG permits other applications in the field of air filtration. At the suggestion of Snow[17] this material has been employed as a tertiary filter in an industrial vacuum cleaner (Kent Quiet Junior) which is suitable for use in hospitals. At a volume output of 135 cu. ft. per minute and at an air velocity of 210 ft. per minute through the medium, a single-thickness pad of Filterdown 50-FG placed upstream from the twin motor intakes retained 99.8±0.2% of nebulized staphylococci either alone or in conjunction with the normal primary (paper bag) and secondary (cloth bag) filters of the machines. The higher efficiency observed at the higher velocity is consistent with arrest by inertial impaction.

The low resistance to air flow of Aerosolve 95 and 85 suggests a possible application in surgical masks. We are currently exploring the use of these materials as a better means of checking bacteria of respiratory tract origin at their source.

Conclusions

A supply of clean air cannot by itself eliminate infection, but a supply of unclean air cannot be tolerated in a hospital. Adequate cleaning of air by filtration through efficient fibrous mediums or by electrostatic precipitation is mandatory for operating rooms, delivery rooms, and nurseries. Performance testing of any installation for high-efficiency fine filtration is essential. If an electronic air cleaner is used, incorporation of an efficient fibrous filter between it and the space being ventilated is essential. Two deep-bed glass-fiber materials were found to provide absolute filtration of bacteria on dust particles and high retention of bacterial droplet nuclei. A glass-asbestos paper intended for hospital use offered retention in the same range.

200 Beacon St. (16).

This study was supported, in part, by the Massachusetts Eye and Ear Infirmary through its Bacteriology Research Fund.

Mr. Werner Mueller Jr. supplied parts of the mechanical equipment, and Mr. David Feigenbaum supplied figure 1.

POISONOUS SNAKE BITES

REPORT OF A CASE

Thomas McCreary, M.D.
and
Harold Wurzel, M.D., Philadelphia

A 39-year-old man was bitten on the back of the hand by a rattlesnake (Crotalus adamanteus) 122 cm. in length. Immediate treatment consisted of suction and application of a tourniquet. Subsequent alarming symptoms were treated by multiple incisions; hypodermic injections of an antivenin; sedation with phenobarbital sodium; venoclysis with sodium chloride, dextrose, and calcium; administration of penicillin and streptomycin; transfusion of whole blood; and the oral administration of atropine, antacids, and diphenhydramine hydrochloride. Systematic observations on the blood-clotting mechanisms showed that clotting could not be induced and fibrinogen was completely absent three hours after the bite. All figures relating to coagulation were normal one day, five days, and six days after the bite, but the patient was not free from symptoms of serum sickness and other complications until the 12th day.

There are 2,500 species of snakes in the world, but less than 200 of them are poisonous to man.[1] In the United States at least 35 species and subspecies of poisonous snakes are known. Estimates on the incidence of snake bite in this country range as high as 3,000 per year,[2] but the death rate from snake bite is low—perhaps 10 or 20 per year.[3] Poisonous serpents are found in 47 of the states, Maine and Alaska being the exceptions. Most of the fatal bites occur in the South and Southwest, where there are more snakes and conditions favor greater exposure. With the increasing popularity of camping and other outdoor activities, there is a possibility that victims of snake bite may become more numerous and the geographical incidence more widespread. Recently we had the opportunity of treating a victim of snake bite. It is incumbent on every physician, regardless of his location, to be prepared for such an emergency.

Report of a Case

A 39-year-old zoo keeper was bitten on the back of the right hand by a 4-ft.-long diamondback rattlesnake (Crotalus adamanteus) on April 23, 1958. Within 10 minutes an incision was made at the bite site and a tourniquet applied at midforearm. The victim sucked at the wound while he was rushed to the Hospital of the University of Pennsylvania, arriving there about 30 minutes after the accident. By this time his hand and forearm were intensely swollen and there were patchy areas of ecchymosis. It appeared that only one fang had penetrated the skin between the third and fourth metacarpal heads on the dorsum of the hand, but there were several other lesser teeth marks. Despite severe swelling and discoloration of his hand, the wound was only moderately painful.

The tourniquet was moved higher on his arm, and the wounds were opened wider. Additional incisions were made on the forearm at the edge of the swelling. Five ampuls of antivenin were injected into the hand and at various levels up his arm. During these procedures the patient first began to manifest evidence of systemic reaction. He began to perspire freely and to complain of perioral numbness that made speaking difficult. Coarse muscle twitches and fasciculations began in his chin and neck and gradually spread to involve virtually all muscle groups. Cyanosis of the lips and tongue was noted. He began to vomit and did so repeatedly for approximately eight hours. Phenobarbital sodium was given parenterally, and his condition was maintained with intravenous administration of dextrose and saline solution, to which was added calcium gluconate in an attempt to control the twitching. Penicillin and streptomycin therapy was instituted.

Saline compresses were applied to his wounds. He was given 500 ml. of whole blood because of continuous ooze from the wounds. Coagulation studies done three hours after admission indicated afibrinogenemia. Fibrinolysins were not found. Because there was no evidence of bleeding except from the sites of the wounds, administration of fibrinogen was withheld. Within 24 hours his clotting functions were almost normal.

The initial hemoglobin value was 13.7 Gm. per 100 ml. Urinalysis disclosed 3+ proteinuria and urine was otherwise free of abnormalities. At no time was there evidence of hemolysis such as hemo-

Assistant Instructor in Medicine and fellow in hematology, Medical Clinic (Dr. McCreary), and member, William Pepper Laboratory of Clinical Medicine (Dr. Wurzel), Hospital of the University of Pennsylvania.

globinemia or jaundice. Red blood cell osmotic fragility was normal. The stool was negative for occult blood.

During his first 24 hours in the hospital, the patient was given an additional 5 ampuls of antivenin, making a total of 10. On the day after admission his hemoglobin level was 10.8 Gm. per 100 ml. and it was assumed that the fall was due to bleeding from the wounds. His systemic symptoms then were abating, and he was able to take nourishment by mouth. The muscular twitching ceased 48 hours after admission. He had moderate fever with peaks to 101 F (38.3 C). Four days after admission his reticulocyte count was 5.2%. The next day the hemoglobin level dropped to 9.6 Gm. per 100 ml. and he developed more fever with elevations as high as 104 F (40 C). At this time his stools gave a 4+ guaiac reaction. Generalized lymphadenopathy became apparent, and he developed an urticarial rash that became confluent and involved almost his entire body. His white blood cell count rose to 11,900 per cubic millimeter with 8% eosinophils. The gastrointestinal bleeding was treated with transfusions and administration of atropine, milk and cream, and antacids. He received only diphenhydramine (Benadryl) hydrochloride to combat the serum reaction. Steroids were avoided because of the gastrointestinal bleeding.

On April 30, seven days after admission, a gastrointestinal series showed changes suggestive of postbulbar ulcer. Late that evening he vomited some coffee-ground material and his abdomen became distended. His stomach was emptied by means of a Levin tube, and feedings were continued after discontinuing the large doses of atropine. The next morning the distention was no longer present and he felt much better. On the 10th hospital day his fever began to abate and he showed rapid subjective improvement. His stools became negative for occult blood. The wounds on his right hand and arm were healing rapidly. On the 13th hospital day the gastrointestinal series was repeated and was interpreted as normal. He had been afebrile for 48 hours when discharged on the 14th day.

Coagulation Studies in Patient with Snake Bite

Test	Normal Values	Results (After Bite)			
		3 Hr.	24 Hr.	5 Days	6 Days

Thromboplastin generation	...	...	Normal	Normal	...

Coagulation Problems

The initial coagulation studies in our patient (see table) suggested that the main defect was afibrinogenemia. All of the abnormalities noted could be explained by the fact that fibrinogen was absent from the blood. We were unable to demonstrate fibrinolysins in the original sample of blood taken three hours after the bite. When added to normal blood or to a 1% solution of fibrinogen, a clot formed, though the clotting process was delayed. When Vipera russelli venom was used as the source of thromboplastin no clot was obtained. This venom will normalize the abnormal prothrombin time if a patient is deficient in proconvertin.

To ascertain the in vitro effects of Crotalus venom on normal oxalated plasma (nine parts of blood to one part of potassium oxalate), lyophilized venom was diluted with saline solution and equal parts (0.2 ml.) of this solution and the plasma were tested. Clotting times were 5 seconds with 1 mg. of venom per milliliter, 64 with 0.2 mg., and 100 with 0.1 mg. Recalcification time of the substrate plasma was 270 seconds. Thus, the venom clotted the oxalated plasma directly without the addition of calcium ions or other factors. It is therefore confirmed that the Crotalus venom converts fibrinogen to fibrin without other factors, as does thrombin.

We believe the thrombin-like activity of the venom eventually led to defibrination of the blood with the resultant incoagulability. The deposition of the fibrin clots must have been in silent areas, for no evidence of thrombosis was found clinically.

Comment

Most of the poisonous snakes in the United States are pit vipers or Crotalidae. These include the numerous species of rattlers (genera Crotalus and Sistrurus), the copperhead (Agkistrodon mokasen), and the cottonmouth or water moccasin (

piscivorus). The coral snake (family Elapidae, genus Micrurus), endemic to the southern states, is related to the cobra and is not a pit viper. All the Crotalidae are front-fanged serpents, generally nocturnal in their habits, and usually capable swimmers. They are equally dangerous on land or in water. They are not aggressive and strike usually only for food or in self-defense.

A number of factors affect the gravity of a snake bite.[4] The age and size of the victim are important. Very young and very old persons are more susceptible to serious aftermath. A bite is less dangerous on an extremity and in tissues where absorption is poor. Bites near vital organs are more dangerous. Intravenous envenomation may result in sudden death.[5] The degree of penetration may vary with the amount of clothing worn, the motion of the victim, and the condition of the snake's fangs. Even the heaviest protective boots and shoes do not always prevent envenomation. Generally, the larger snakes are more dangerous because they are capable of injecting greater quantities of venom. Snakes are likely to carry pathogenic micro-organisms in their mouths, most commonly the clostridial organisms of tetanus and gas gangrene. The initial emergency first aid can alter the outcome of a snake bite. If possible, the snake should be accurately identified. Bites from nonpoisonous snakes usually produce superficial scratches, and far less drastic therapeutic measures are required.

The venoms of poisonous snakes consist of complex proteins, enzymatic in nature. They vary in potency from species to species and within a single species, depending on the habits and physical condition of the snake. The amount injected may be from a few drops to 2 ml. per strike. The larger rattlers may inject up to 500 mg. of solids in a single ejection, the water moccasin up to 200 mg.[2] Most venoms contain hyaluronidase, which enhances the rapid spread of venom via the superficial lymphatics.[6] The deeper lymphatics become involved proximally, i. e., at the knee, groin, and axilla. Virtually none of the venom is disseminated via the blood.

The toxic parts of all snake venoms fall into three main categories: proteases, phosphatidases, and neurotoxins.[2] The proteases produce destructive effects at the bite site and play a role in remote visceral hemorrhage. The venom of some snakes (e. g., most rattlesnakes) acts as thrombin, converting fibrinogen to fibrin in the absence of other clotting factors. Others (e. g., Vipera russelli) have thromboplastic activity and convert prothrombin to thrombin.[5] There is damage to vascular endothelium, and fibrinolysis is also frequently seen.[7] The phosphatidases are reponsible for hemolysis. They also alter excitability and conduction in skeletal, smooth, and cardiac muscle. Lysolecithin is formed from lecithin, and this enhances hemolysis and produces hypotension via the release of histamine. Small blood vessels may be destroyed by these enzymes, and capillary permeability is altered. The neurotoxins of coral snakes and cobras may produce a curare-like effect at the myoneural junction, interfere with nerve trunk conduction, or act directly on the central nervous system. Death from neurotoxins frequently is the result of bulbar paralysis.

Coral snake and cobra venoms are chiefly neurotoxic, unlike the rattlesnake venoms which contain little neurotoxin, though there are exceptions. All venoms hemolyze blood, but red blood cell lysis is rarely complete, even with high titer venoms. There tends to be an inverse relationship between lethal toxicity and the ability to produce local necrosis.[8] The hyaluronidase of venoms is not of itself toxic. It is antigenic, however, and specific antiserum inactivates it.[6]

Treatment

The treatment of snake bite is more effective the earlier it is started. Since most bites occur in areas remote from a physician's office, the victim himself must usually apply the first aid. If he can remain calm, he will not only work more efficiently but will reduce the speed of systemic spread.

The first step, application of a tourniquet, has been an acceptable procedure for many years. However, recent investigations have cast doubt on the efficacy of this maneuver. The objective was to occlude the superficial lymphatics so as to lessen systemic diffusion of venom. It is thought by some that occlusive bands intensify local tissue destruction without preventing spread of the toxins.[9] Incision and suction at the bite site is another time-honored procedure no longer utilized by some physicians with extensive snake bite experience. On the other hand, Jackson and Harrison [10] offered rather convincing evidence that early suction results in removal of large quantities of venom. If this method is used, incisions need be made only to the depth of the subcutaneous tissues and suction begun by mouth, suction bulb, or whatever else is available.[11] The venom is harmless when taken orally unless there is a break in the mucosa. As swelling extends beyond the site of envenomation, short linear incisions may be made at the edge of advancing swelling and suction applied over the incisions. If the bite is on a limb, a series of incisions may be made to encircle the limb. If a tourniquet is used, it should be moved proximally in advance of the swelling and applied lightly enough that arterial blood flow is not compromised.

While extensive local excision has been advocated,[12] in most cases this would seem unnecessary unless obvious necrosis or severe infection is present. The use of ice packs and other cooling measures has met with some favor. This appears to lessen necrosis, to slow absorption of venom, and to prevent extensive tissue loss.[11] However, it is not universally accepted as a method of treatment.[14]

Unquestionably, snake bite victims often survive without the use of antivenin.[15] Deferring its use, however, presupposes considerable knowledge and experience in snake bite, which most physicians do not have. Hence, if there is any reason to believe that the bite may be serious, antivenin should be used, after first taking the precautions routinely advised before administering any horse serum preparation. The antiserum commercially prepared as antivenin (Crotalidae) polyvalent (North and South American anti-snake-bite serum) contains effective titers against all poisonous American snakes except the coral snake. The dried serum is supplied in a kit containing 10 cc. of sterile water for reconstitution and a disposable syringe that can be used as an aspirating apparatus after the serum has been injected. If kept in the dry state, the serum is stable for at least five years without refrigeration.[16]

The amount of antivenin to be given must vary. A smaller person requires a larger dose because the venom, distributed in a smaller volume, is less dilute. If the patient is seen within two hours of his accident, he should receive half the initial dose in the vicinity of the bite and the other half intramuscularly or subcutaneously in the affected part. A total of one to five vials (10 cc. each) may be used as a first dose. If swelling and necrosis persist and advance, more antivenin may be given every one-half to two hours until the process is arrested. A comatose patient or one in shock may require intravenous administration of antiserum. The possibilities of serious allergic reactions to the horse serum cannot be too strongly emphasized, and these must be anticipated if the treatment is not to be worse than the disease.

Snake bite is always a medical emergency, and every victim should be hospitalized. Blood typing and crossmatching should be done as soon as possible, because toxins from the snake bite may later render this impossible. Frequent blood cell counts and urinalyses are required for early detection of hemorrhage and hemolysis. The possibility of visceral or cerebral hemorrhage must be kept in mind. It may be possible to uncover a coagulation defect that would respond to specific therapy. Afibrinogenemia, if attended by massive bleeding, may require infusions of fibrinogen to control the bleeding. Most victims will be unable to take fluids orally because of vomiting. Intravenous infusions of dextrose and saline solution should be started to maintain hydration. In the event of severe hypotension or shock the patient should be given transfusion with whole blood and vasopressor agents used as indicated. Calcium gluconate may be given in the infusion to counteract unpleasant muscular twitching. Antibiotics probably should be used regularly because of the threat of infection. The routine use of tetanus and gas gangrene antitoxins has also been advocated. Antihistaminics may be useful in counteracting the effects of the histamine that is released by some venoms. Generally, the patient is thought to be out of danger if he survives the first 48 hours. Relapses occur rarely and are often due to infection or gangrene. Amputation may occasionally be lifesaving if tissue necrosis is extreme. In any case, careful, prolonged follow-up study is necessary.

Summary

In a case of rattlesnake bite with survival, afibrinogenemia occurred as a result of the thrombin-like action of the venom. Gastrointestinal bleeding and serum sickness also developed.

3600 Spruce St. (4) (Dr. McCreary).

Louis Spitz, M.D., and Mr. Roger Conant (Curator of Reptiles, Philadelphia Zoological Garden) assisted in this study.

This study was supported in part by Abbott Laboratories, North Chicago, Ill.

The lyophilized venom used in the coagulation experiments was supplied by Mrs. Eleanor Buckley, Wyeth Laboratories, Inc., Philadelphia.

MEDICAL CARE UNDER THE HEALTH INSURANCE PLAN OF GREATER NEW YORK

Edwin F. Daily, M.D., New York

House, office, and in-hospital care under the Health Insurance Plan is provided to 550,000 persons by physicians who work almost exclusively in groups. The 32 groups operate medical centers in which more than 10 million dollars have been invested. Qualifications of group physicians are determined by a medical control board, and professional education programs for group members are provided. The quality of surgical, medical, obstetric-gynecologic, pediatric, laboratory, and x-ray services has been thoroughly evaluated, and the other departments are currently under review by specialists outside of the plan. Each medical group receives equal annual capitation for each insured person selecting that group, and each group operates its own plan of paying its distributable income to physician members. The accumulation of experience is enabling the organization to move steadily in the direction of comprehensive medical care of high quality.

Innumerable inquiries have come to the Health Insurance Plan of Greater New York (H. I. P.) from practicing physicians, medical students, health insurance organizations, medical societies, labor unions, and others asking about the plan. This paper has been prepared to help answer some of the often-raised questions.

The Health Insurance Plan of Greater New York, because it provides medical care and not cash indemnities, is obligated to establish professional standards and to organize its activities so that subscribers will be assured a high quality of medical care. The following standards and methods are among those set by the H. I. P. and developed by it to achieve this quality.

Group Practice

Home, office, and in-hospital medical care in the H. I. P. is provided to 550,000 persons by physicians who work in groups (except for 1.7% of the enrollees who live outside of the areas in the seven counties served by the 32 medical groups). Group practice has been defined by the H. I. P. as "provision of preventive, diagnostic, and curative medical services by family physicians, specialists, and other professional and technical staff working as a team in a group center, pooling their knowledge, experience, and equipment, as well as income." The scope of medical care provided by the H. I. P. is shown in the table.

The founders of the H. I. P. believed that the close professional association of physicians in group practice at adequate medical centers would inevitably result in better medical care than could be provided by physicians working alone. One of the major reasons physicians become associated with medical groups in the United States, they say, is that they believe it will enable them to practice better medicine.

All group physicians must meet the professional standards established by the H. I. P. medical control board, as will be discussed later. Each family physician in a group has readily available to him, and without additional cost to his patients, the serv-

---

Vice-president, Health Insurance Plan of Greater New York.

ices of specialists in all of the clinical fields (medicine, pediatrics, surgery, obstetrics-gynecology, orthopedics, ophthalmology, otolaryngology, dermatology, urology, neurology, radiology, pathology, and psychiatry), as well as in the laboratory, x-ray, and physical therapy departments. (Each medical group has a psychiatrist who provides psychiatric diagnosis and consultation. The H. I. P. coverage does not provide for psychiatric treatment by psychiatrists.) The 32 medical groups have over 1,000 physicians; approximately one-half are family physicians and the other half specialists. Most of the group physicians (80%) are partners. The new group physicians start under contracts. Each medical group elects its own medical director and establishes appropriate committees. Each clinical department has a chief responsible for supervision and administration of his department in the group. Professional work schedules are arranged in almost all of the groups, or between groups, for emergency night and week-end calls and vacations in order to enable all participating physicians to have free time for rest, research, and study.

Scope of Medical Services Provided by Health Insurance Plan of Greater New York

Services Provided Under H. I. P. Contracts

- General medical, specialist, surgical, and obstetric care
- Laboratory and diagnostic procedures
- Periodic health examinations, immunizations, and other measures for prevention and detection of disease
- Physical therapy, radiotherapy, and other therapeutic measures
- Professional services for the administration of blood or plasma
- Eye refractions
- Visiting nurse service at the insured person's residence as prescribed by a physician of the group
- Ambulance service from the insured person's residence or, in an emergency, from other locations within the area served by the group to a hospital when ordered by a physician of the group

Services Not Provided Under H. I. P. Contracts

- Medical services for acute alcoholism; drug addiction; tuberculosis, during the period that the insured person is confined as a patient in a sanatorium or special hospital or if recommendation for such confinement has been made by a licensed physician and facilities for such confinement are available but have been rejected by the insured person; psychiatric disorders, after diagnosis, for which care is customarily provided by a psychiatrist; chronic illnesses in an institution other than a hospital for general care; artificial insemination; and anesthesia if administered in a hospital or if administered by an approved anesthesiologist in a medical group center
- Cosmetic surgery, except procedures needed for the treatment of congenital anomalies so as to restore a part of the body to its proper function and procedures to correct a serious disfigurement or serious deformity caused by a disease or injury treated during the patient's coverage under the H. I. P.
- Electrolysis for epilation
- Services for dentistry or dental surgery
- Prescribed drugs and biologicals used for prevention or treatment of disease, prosthetic appliances, eye glasses, blood, plasma, and other substances ordinarily provided by donors
- Special duty or private nursing service

Utilization of Services by Insured Persons (1957)

- 75% of all enrollees receive medical service during a year; average number of medical services received by all enrollees per year is 5.36, with a high of 15.5 services per year for children under 1 year of age and a low of 3.7 services per year for those between the ages of 15 and 20; 80% of all medical services are provided in physicians' offices, 9% in patients' homes, and 11.3% in hospitals
- Breakdown of number of physicians' services per 100 enrollees per year, as provided by type of physician:

Family physicians and internists	268
Pediatricians	60
Radiologists	44
Obstetricians-gynecologists	42
General surgeons	27
Allergists	21
Ophthalmologists	19
Orthopedists	16
Otolaryngologists	14
Dermatologists	14
Urologists	8
Other	4

Ages of enrollees

- 28.4% under 15 years
- 15.5% over 55 years

Cost

- The premiums for group enrollment are $42.72 per year for one person, $85.44 for a man and wife, and $128.16 for a family with children. These rates are 21% higher if the income of an individual subscriber is over $6,000 per year or if family income is over $7,500 per year. (All subscribers must also carry hospital insurance at the time of enrollment.)
- The average premium income per insured individual is approximately $36 per year, varying each year in relation to the number of children in families since the premium is the same for a family with one or with several children and varying with the percentage of enrollees in the upper income rate.
- Under New York State law, 4% of the premium income is placed in legal reserves until a reserve of 25% of premium income is reached. Of all premium, 88% is paid to the medical groups. The remainder covers the H. I. P.'s costs of maintaining its medical department, research, statistics, and general administration.

Since each subscriber has his choice of any medical group serving his community and then, within the group chosen, makes a choice of a family physician, there is healthy competition among groups to provide the best possible medical care. Each medical group has learned that its economic future depends on how satisfied its own subscriber-patients are, for subscribers are soon aware of inadequacies in physician attitude or administrative procedure.

The Medical Group Centers

The 32 medical groups affiliated with the H. I. P. have invested over 10 million dollars in medical centers. Each medical group is required to have a center with the following facilities: 1. Sufficient consulting and examining rooms to provide all ambulatory specialty services without delay in appointments. Because of the large geographical areas now covered by most of the medical groups, many family physicians and pediatricians also provide services in offices nearer the homes of their subscriber-patients. However, these physicians also have scheduled hours set aside each week for appointments at the center. 2. A fully equipped clinical laboratory with trained technicians under the supervision of an approved pathologist. 3. An x-ray department with trained technicians under the supervision of an approved roentgenologist. 4. A physical therapy department with at least one licensed physical therapist and equipment for the usually accepted modalities of treatment. 5. Equipment for electrocardiography, basal metabolic rate determination, and similar procedures. 6. Uniform medical record systems.

It is our experience that, whenever physicians are brought together to work in one center and share modern equipment and facilities, the ease of consultation and the stimulation of professional contact bring about the desire and effort to achieve and maintain high levels of performance.

Qualifications of Physicians and the Medical Control Board

Prior to participation in the work of the medical groups, all physicians have their training and experience reviewed and approved by an impartial medical control board composed of 18 leading physicians, the majority of whom are not affiliated with the medical groups. The contracts between the Health Insurance Plan and the 32 medical groups require that the groups and their physicians abide by the policies and regulations adopted by the medical control board.

Examples of standards of training and experience adopted by the medical control board are as follows: (1) for chiefs and associate chiefs of all of the 12 basic specialties, certification by the American board in the respective specialty and appointment as attending, associate, or assistant attending physician on the staff of a hospital approved by the American Medical Association for resident training in the specialty; (2) for assistants in each specialty, completion of training required by the respective American boards; (3) for family physicians (several of the medical groups employ as family physicians only diplomates of the American Board of Internal Medicine or physicians who have completed the training required by this board), graduation from a medical school approved at the time of graduation by the American Medical Association, an internship for a period of at least one year in a hospital approved for internship by the American Medical Association, a residency or fellowship in internal medicine for a period of at least two years in a hospital approved by the American Medical Association for residency or fellowship in internal medicine (adopted June, 1957) or a staff appointment in medicine for the five years preceding the date of consideration of the candidate by the medical control board in a voluntary or municipal hospital approved for residency training in internal medicine by the American Medical Association (adopted June, 1957), and appointment in medicine on the staff of a voluntary or municipal hospital approved for residency training in internal medicine by the American Medical Association, personal interview by members of the medical control board regarding training and experience, and a written test in clinical medicine prepared by a national testing organization skilled in this field; and (4) for consultants in specialized fields of surgery (approximately 80) serving all medical groups (cardiac, plastic, brain, thoracic, head and neck, pediatric, stapes, fenestration, and others), certification by the American Board of Surgery, appointment as attending or associate attending physician in the specialized field in a hospital having the personnel and equipment necessary for the proper performance of operations, and demonstrated proficiency in the specific specialized field.

The medical control board requires a base-line history and physical examination for each new adult enrollee as soon as feasible after joining the medical group of his choice. It has established requirements that maternity care be provided by obstetricians and that pediatric care, at least for children under the age of 3, be provided by pediatricians. Some of the medical groups provide care by pediatricians to the age of 6 and some to the age of 12 years.

Professional Educational Programs

Each of the medical groups has monthly clinical staff meetings to discuss case reports, morbidity, and mortality and to review clinical subjects selected primarily by the family physicians. The H. I. P. has an educational fund used to defray one-half of the cost of tuition for postgraduate courses taken by the physicians. A foundation has made available to the H. I. P. funds to pay research fellowships for selected young physicians becoming affiliated with the medical groups.

A consultant specialist in physical medicine is available to the medical groups to discuss regularly how the skills of this relatively new medical specialty can assist in the care of patients requiring rehabilitation. Two consultant dietician-nutritionists have been employed by the H. I. P. to work with the medical groups in developing group therapy for obese, diabetic, or other types of patients in need of special diet discussions and to develop the type of diet instructions most suitable for the population groups served by the medical groups. A maternity nurse-teacher has been employed by the H. I. P.

(with the aid of a grant from the U. S. Children's Bureau) to develop classes for expectant parents in cooperation with the obstetrician-gynecologists in each medical group. A specialist in medical records is employed by the H. I. P. for consultation with the medical groups and individual physicians on all aspects of maintaining acceptable records and for the development of systematized follow-up studies of all patients with serious or potentially serious illnesses who fail to return for needed medical care.

A staff of five full-time consultants in community resources (skilled social workers thoroughly familiar with more than 2,000 voluntary and public agencies related to health and welfare in New York City) are employed by the H. I. P. to assist the subscribers and physicians in dealing with the difficult problems of obtaining appropriate convalescent home care, household aid, admission to mental institutions, appliances for the handicapped, vocational rehabilitation, and other services.

A staff of six full-time, professional health educators is employed by the H. I. P. to assist the physicians individually and in medical groups to discharge their roles as teachers of sound health information and attitudes and as counselors of wise health practice during illness and health. The health educators guide the development of a wide variety of educational activities, all with the sponsorship and participation of the physicians, including periodic bulletins, a variety of subscriber-physician meetings, pamphlets, films, and intimate discussion groups.

Method of Payment for Medical Care and Subscriber Relations

Method of Payment for Medical Care.—The fee-for-service method of payment is not used in group practice under the H. I. P. Instead, each of the 32 medical groups at present is paid $31.80 per year for each person enrolled in a group (this includes $1.20 per enrollee for a pension fund for group physicians). For this capitation the medical groups agree to provide all medical care covered by the contract and needed by their enrollees. After each group has paid its overhead and administrative costs, the income remaining is distributed to physicians on the basis of such factors as number of hours spent in the work of the group, number of years of postgraduate training, and length of time served in the group. Each medical group has its own formula for disbursing its distributable income to its physicians. The security of an assured income and retirement program, the relief from discussing fees and from sending and collecting medical bills, and the knowledge that costs will not deter patient cooperation permit the H. I. P. physicians to be primarily concerned with the provision of good medical care.

Participating physicians are not permitted to make extra charges to or accept payments from or on behalf of the H. I. P. patients for services covered under the H. I. P. contracts, irrespective of the family's income or of the type of services provided, except that they may charge $2 for a home call requested and made after 10 p. m. and before 7 a. m.

Subscriber Relations.—When persons enroll in the H. I. P., every effort is made to acquaint them fully with the services available and how to use them to maximum advantage. They are encouraged to discuss any dissatisfaction with medical services or administration with their medical group directors and to offer suggestions for improvement of the plan. Complaints and suggestions for improvement are discussed by the medical group directors with all of their physicians and staff at monthly meetings.

The H. I. P. maintains a subscriber service division at its central office where written and telephoned inquiries, complaints, or claims from persons and expressions of praise and appreciation are received. Complaints are given careful individual attention and are discussed by the H. I. P. medical staff with the appropriate medical group directors. Copies of all complaints received by the H. I. P. are sent to the appropriate medical groups, and written replies are required. The medical administrative staff of the H. I. P. may find it necessary to interview the persons concerned and to make recommendations for appropriate handling of the complaints. Reviews of all complaints are made by the H. I. P. and are submitted to the medical groups at regular intervals. The methodology of handling any complaint or claim promptly and fairly has minimized malpractice claims.

With the guidance of the H. I. P.'s health education staff, medical groups sponsor quarterly bulletins which are mailed to subscribers and hold periodic night meetings with their subscribers for the purpose of discussing problems related to health and medical group care of interest to subscribers.

These bulletins and meetings, in addition to dealing with such subjects as infant care, mental health, health problems of elderly people, nutrition, and literally many dozens of other health areas, have also dealt with such matters as how a medical group functions, appointment systems, laboratory and other diagnostic procedures, doctor-patient relations, and a wide variety of administrative matters. Several medical groups have developed advisory subscriber committees.

In all instances the fundamental aim is to bring the physicians in a group and its subscribers closer together. The medical director and his administrative staff are involved in the preparation of the bulletin and are always present to lead the discussion and to answer questions at subscriber meetings. Many physicians were at first apprehensive about meeting with large numbers of subscribers, fearful that they would be overwhelmed by unwarranted and intemperate criticism. The results have been quite the contrary.

Complaints are solicited and aired at these meetings, as they are in the bulletins. Many valuable suggestions for facilitating the work of the group in the interest of subscribers have been made at these meetings to the advantage of all concerned. The group directors take immediate steps to bring about any necessary changes and thus avoid future complaints.

The group physicians have learned that properly conducted meetings and carefully written bulletins provide an excellent opportunity to discuss with their subscribers many practical and difficult problems in the provision of good medical care. For the subscribers a feeling of sharing with their physicians in the success of their medical group has been achieved.

The methods described permit all subscribers to have a direct part in influencing the quality of medical care. A favorable attitude of subscribers toward their medical groups or toward their individual physicians is essential for the success of any medical group, for dissatisfied subscribers may readily transfer to another medical group or to another physician within a group.

Studies of the Quality of Medical Care

During the past three years, the H. I. P., with the cooperation of the medical groups, has thoroughly evaluated the quality of surgical, medical, obstetric-gynecologic, pediatric, laboratory, and x-ray services provided in each of the 32 medical groups.[1] This study was made by professional leaders in each specialty field who were not otherwise affiliated with the H. I. P. For each physician studied, the H. I. P. selected a sufficient number of clinical records to evaluate fully the competence of the person. Any physician whose score was unsatisfactory and who remained in the medical group at the conclusion of the study was given individualized educational guidance by his medical group and was repeatedly restudied until his work was satisfactory or he resigned from his medical group. (It was interesting to note, in the pediatric portion of the study, that 95% of all the H. I. P.-insured infants were immunized against whooping cough, diphtheria, tetanus, and smallpox in their first year of life.) As the study of each medical group was concluded, the medical care study team met with the group physicians to discuss fully all of the findings and recommendations for each department and each physician. The departments of orthopedics, urology, allergy, ophthalmology, and otolaryngology are now being evaluated by a new medical care study team.

A recent study by the New York City Health Department and the H. I. P. of the perinatal mortality in New York City showed that the rate for the H. I. P. enrollees (expressed per 1,000 live births and fetal deaths) was 21.3 as compared with 30.1 for all private patients in New York City.[2] Continuing studies are being made for two additional years, including coding in all cases the training and experience of the attending physicians. It is believed that these further studies will show that the difference in the rates is related primarily to the fact that in the H. I. P. only specialists provide maternity care and pediatric care of newborn infants. Other studies are being made of the stage of development of cancer when first diagnosed in the medical groups and the relationship between morbidity in the pregnant woman and the outcome of pregnancy.

Recently a report by the H. I. P. on prepaid medical care and hospital utilization was published by the American Hospital Association.[3] The hospitalization experience of two populations having the same hospital insurance coverage, but different coverage for medical care, was compared in the study. The two populations were those of the H. I. P. and United Medical Service (Blue Shield) in New York City. It was found that the annual hospital admission rate for the H. I. P. population was 77.4 per 1,000 as compared to 94.8 for the Blue Shield group. It was also found that the duration of stay, expressed as the number of days per 100 population per year, was 55.8 days for the H. I. P. and 68.8 for Blue Shield group. There was little difference in the average duration of stay per admission.

The various administrative measures described here reflect a strong desire to provide care of high quality. Of course, the H. I. P. has not met with complete success in its efforts, and some administrative obstacles have arisen. However, the organization has profited, and continues to profit, from its experiences and year by year is moving closer to the complete fulfillment of its goal—the provision of comprehensive medical care of high quality through full-time medical groups with modern medical facilities.

625 Madison Ave. (22).

A SMALL COMMUNITY HOSPITAL HANDLES A DISASTER

James E. Segraves, M.D., Chicago

Several basic factors appear important in planning a program for handling of mass disaster victims by a small community hospital. The first 24-hour treatment program must be outlined in detail. Team approach is the only logical one, with provision for alternate chiefs. Frequent practice sessions are necessary, and stockpiles of dressings, drugs, aged plasma, and electrolytes must be kept available. In any sizable disaster, the exposed method is the only way to handle burn cases. Identification tags for school children appear desirable. Police should have information about available hospitals in given areas and their casualty capacity. The hospital involved in the situation reported here, a school fire, has 350 beds.

On the afternoon of Dec. 1, 1958, fire broke out in Our Lady of Angels' school in Chicago. Within 15 minutes patients began to arrive at St. Anne's Hospital in Chicago. This is a small community hospital with 350 beds. The way in which St. Anne's Hospital handled this emergency situation is outlined below, demonstrating what can be done if everything and everybody is ready.

The Plan

The disaster plan at St. Anne's Hospital has been under consideration for the past eight years and, in that time, has undergone many changes until it has arrived at its present form. The plan as it has been worked out is voluminous, since it presumes many degrees of disaster from a few assorted victims to the thousands resulting from a nuclear explosion. Its success, in any degree of disaster, depends on many factors, not the least of which is a clear understanding by all concerned of their duties, an adequate stock of supplies ready to be used at a moment's notice, an acceptance by the members of the medical staff of the team plan of treatment, and the presence, in the receiving pavilion, of a man or men capable of rapidly evaluating the nature of the injuries. He must have knowledge of the medical talent available so that the patients may be assigned to the proper departments for immediate emergency care and definitive treatment.

In the long run the plan calls for frequent staff meetings, usually, as in this case, on a daily basis, to bring everyone up to date as to the situation as of that moment, to suggest changes in routine treatment, and to advise the team as to the available supplies. Reports are received from the members of the team and suggestions from the men are solicited and evaluated. Then the plan for treatment for the next 24 hours is outlined.

In other words, until all of the patients are out of danger, care is kept on a 24-hour basis under the immediate and tight control of a team of physicians designated by the staff at the time of the first meeting. The team includes those best suited, in the opinion of the assembled staff, to care for the injured patients, the decision being based on the character of injuries sustained. The meetings must, at all times, be under strict control of the head of the disaster team and/or his designated representatives.

How It Worked

The plan worked in this particular disaster as follows: The emergency room staff notified the administrator of the hospital of the state of disaster, and the administrator called the chairman of the disaster plan, the director of nursing, the director of household activities, the director of nonprofessional personnel, and the switchboard operator (to notify physicians and summon them to the hospital).

The chairman of the disaster plan responded immediately and was informed by the administrator of what appeared to be the extent of the disaster. He assigned men to duties as they reported to the hospital. Cases were noted and provision was made for physicians to care for the following groups: ambulant patients (with instructions to discharge them to their homes if possible), those with minor injuries, those with serious injuries requiring hospital care but no immediate operation, and those requiring immediate surgical care. The chairman of the team and men designated by him evaluated the patients as they were admitted and directed that they be taken to the previously designated centers, depending on the character of the case, as noted above. Centers would vary according to the size and character of the disaster and available facilities.

As soon as all of the patients were evaluated and disposed of, the chairman proceeded to conduct rounds of all the various treatment centers to see that all was going well and to offer suggestions where indicated. These rounds were repeated time after time until all of the patients were put to bed and therapy started. The chairman then called a meeting of the men present to receive reports and outline the first 24 hours of care according to the problems at hand and to designate the team to be responsible for carrying out such care.

Director of Disaster Plan, St. Anne's Hospital.

The director of nurses mobilized all nursing personnel and put in a call for volunteers and off-duty personnel. She assigned nurses, according to the plan, to the emergency room, emergency wards, surgical services, and the various floors; the duty in the latter was to make rooms ready to receive patients as soon as they received appropriate emergency treatment. This was done under the direction of physicians previously so designated and assigned.

The housekeeper set up tables of supplies in operating rooms, in the emergency receiving pavilion, and in the various treatment centers as planned. These supplies, at this hospital, are on hand to care for at least 50 patients, with more available for use in a relatively short time. The pharmacy prepared a list of the drugs available and consulted with the chairman of the disaster committee to determine whether any additional amounts of such drugs or other drugs would be needed. A report as to the available supplies of colloids, including whole blood, was given to the disaster chief, who estimated the amount that would be needed for the first 24 hours. Supplies of electrolytes were checked to assure sufficient quantities for the first 24 hours.

The director of nonprofessional personnel dispatched persons to attend the entrances to the hospital and direct visitors to the proper areas, families of possible injured being referred to a lounge previously designated as the relatives' lounge, where they were registered for identification. He personally communicated to the families the periodic reports as to the identity of injured persons in the hospital as soon as it was possible. All telephone inquiries were directed to a person so designated, and members of the press were directed to the director of public relations. Periodic lists of families and patients were made up by the medical staff secretary, and communication with other hospitals was maintained to locate relatives. The administrator of the hospital coordinated all of these activities and enforced decisions of the disaster team.

How Patients Were Handled

Physicians, including the disaster chief, began to arrive within 15 minutes after the arrival of the first patient, and within 40 minutes 80% of the staff was present and assigned to treatment centers. The receiving pavilion was empty within one hour and 15 minutes, except for six patients who were dead on arrival and had been placed in a previously designated room and four other patients apparently beyond medical help who died soon after their arrival.

Within two and one-half hours all 46 patients were in bed and given care for their burns. Administration of fluids had been started, sedatives, tetanus antitoxins, and toxoid given, Foley catheters inserted, and, in most cases, definitive care instituted. There were, in addition to the burns, a multiple list of other injuries, and definitive care given immediately included two tracheotomies, a screw in the olecranon process for skeletal traction to a supracondylar fracture of the humerus, a Steinmann pin in the os calcis for a fracture of the femur, five moulded plaster splints for fractures of the os calcis, manipulation, reduction, and casting of three Colles' fractures, manipulation and reduction of one fractured tibia and cast, and the application of Crutchfield tongs for traction on a dislocated cervical spine. Other injuries included basal skull fractures (at least two patients), compression of the lower dorsal and lumbar regions of the spine, fracture of the pelvis (six), fracture of facial bone (two), fracture of the spinous process of the vertebral bodies (one), fractures about the ankle (four), fracture of neck of the humerus, and tension pneumothorax for which water seal drainage was started. A Bennett positive-pressure machine was used in two cases.

At the first meeting, held at 8 p. m., the over-all management of the patients was assigned to two pediatricians and one internist. The care of the children's burns, in the initial stage, was assigned to the orthopedic department, and at their suggestion the exposure treatment was decided on for all patients. These decisions were approved by the members of the medical staff present. At the initial meeting it was suggested that Stryker frames be secured, and within 16 hours these were being used in 14 cases. Shock was treated with dextran, plasma, and whole blood and also isotonic sodium chloride solution and lactated Ringer's solution, replacement being made on the basis and the character of the loss; for instance, replacing blood with blood according to the Brooke formula. Chlorothiazide (Diuril) and lyophilized urea were given where indicated. Antibiotics were given immediately, penicillin-dihydrostreptomycin (Combiotic) the first 24 hours and then specific antibiotics as indicated by sensitivity tests. Large quantities of bacitracin and polymyxin-B, and also ristocetin (Spontin), were used with no complications.

The burns themselves were second-degree and third-degree in most cases. The extent of burns was 60% or more in six children, with 90% in one and 80% in one. The rest were burned for varying degrees up to 40%, and four had third-degree burns of the face, including the eyelids, hair, and scalp. Six others had involvements of the ear but not the eyes. Eschars were formed in the first 48 hours. Débridement and skin grafting were first started on the 15th day after patients were admitted. Of the 46 patients admitted, one died early in the second week of a basal skull fracture and septicemia. A second died in the third week of overwhelming bacteremia. In the latter patient, at autopsy all of the vital organs were found to be riddled with abscesses. In those few patients in whom urinary output was temporarily interrupted it was resumed within 12 hours with no further difficulties. Ten of the patients developed bacteremia but recovered satisfactorily, except for the two as noted. The remainder of the patients progressed satisfactorily, and all but 10 of the remaining 44 had been discharged from the hospital by the end of the fourth week.

The skin grafting was under the direction of the surgical department, and autografts were used where available but, in at least three of the patients, lyophilized homografts supplied by the Department of the Navy were used as temporary dressings. At the débridement and skin grafting stage, an aerosol spray containing a 1% solution of neomycin and bacitracin was used with excellent resuts.

What Went Wrong.—Identity was often incomplete, and even parents were unable to identify for sure some of the more severely burned children. A system of multiple tagging on admission would benefit those concerned with seeking victims and reuniting them with relatives. Physicians and other personnel, including volunteers, had difficulty getting to the hospital because of the crush of automobile and pedestrian traffic. Adjustment to the team approach was difficult at first but was made satisfactorily.

Comment

This plan worked at this hospital but would, of course, have to be adjusted to meet the needs of each individual hospital. Several points appear now in the light of this experience to be most important in planning any kind of program for handling mass disaster victims:

First, the plan must be simple. Obviously, as the plan becomes more complicated the degree to which physicians, nurses, and nonprofessional personnel can be familiarized with its workings decreases proportionately.

Second, mass disaster situations must be postulated and the first 24 hours' treatment for the commonly expected problems, such as burns and fractures, must be outlined in detail. When the disaster occurs it is too late to plan for treatment.

Third, it is apparent that the team approach is the only logical one if chaos is to be prevented, and the team must be under the direction of one man, the disaster chief, who is thoroughly familiar with his job. Alternate chiefs should be trained in the event the disaster chief is not available.

Fourth, frequent practice sessions are necessary in order to familiarize all personnel with their part in the plan. These frequent trial runs are also important since, particularly these days, nonprofessional help varies from week to week.

Fifth, stockpiles, based on the outlined 24 hours' treatment, must be kept available. This applies not only to dressings and drugs but also to aged plasma and electrolytes. A readily available source of whole blood should be provided at all times.

Sixth, when the majority of the cases are burns, the exposure method of treatment appears to be the best and, in any sizable disaster, is the only way to handle burn cases. It requires much less stockpiling than the less-satisfactory, closed pressure method.

Seventh, the problems of identification among children, since they so infrequently carry wallets or other identification, make the idea of identification tags for school children a desirable thing.

Eighth, in planning for a disaster, it would be well if the personnel of each police district were familiar with the hospitals in their district and had on record an estimate of the number of casualties each could care for at one time.

The most significant conclusion to be drawn from this experience is that a small community hospital, properly prepared and aware of the problems involved, can handle a mass disaster.

4849 Fullerton Ave. (39).

TOWARD A SAFER HOLIDAY.—During the first 30 years of this century more people were killed and injured celebrating the nation's independence than in the War of Independence itself. Fireworks killed 4,290 persons and severely injured 120,000, as compared to the Revolutionary War of 4,044 dead and 6,600 wounded. . . . Right across the country there is a pattern of illegal sale of fireworks. . . .

The biggest operators, of course, are professional bootleggers. In 1956 the Bergen County, N. J. police were reported to have said that illicit trade in firecrackers, Roman candles, skyrockets, cherry bombs and other dangerous fireworks had reached the highest level since 1937, when the New Jersey control law went into effect. . . . Several states have no control laws, and bootlegging is still a serious problem. . . . When the laggard states join their sisters in passing the model control law, and when interested citizens in all states remain alert to the many dangers still inherent in our manner of celebrating our national birthday, it will deserve its rather premature title of "glorious."—Helen Augur, Gaps in Fireworks Control, *The Sight-Saving Review*, Spring, 1959.

MEDICAL RESPONSIBILITIES IN A CHANGING WORLD

Gunnar Gundersen, M.D., LaCrosse, Wis.

I do not have to prove to this group that this is a changing world. Nor do I have to demonstrate that medicine is also changing. Nevertheless, I want to outline briefly three important areas of change in America that are affecting, and will affect, medicine profoundly.

Population, Social, and Scientific Changes

At the 54th Annual Congress on Medical Education and Licensure last year, we learned from Dr. Dudley Kirk and the workshop session that the United States currently is undergoing the largest absolute increases in population in its entire history. Approximately 3 million persons are being added annually, and in 20 years we may expect to have a national population of 240 million.

In addition to pure numbers, our population also is being redistributed. The suburbs are continually outgrowing their boundaries, and now the flight is to exurbia, or to the more open spaces.

The age of our population is changing too. Today the nation grows younger and older at the same time. Present baby booms are keeping the population young, while the increasing numbers and proportions of older citizens advance the age of the population.

Within this growing population certain other social and economic changes are taking place. As Dr. Kirk pointed out, there is "a consistent trend toward upgrading the standard of living, the occupational class and the educational standards of our people."

Perhaps these three—income, occupation, and education—are in reverse order, for we know that, as education builds up the capacities through learning, the number of skilled and clerical workers and managerial and professional persons increases. These new positions then generally bring higher incomes.

One result of all this has been a raising of living standards. Important also is the fact that a person today is "what he can do," not "who he is" in terms of social class or ethnic, religious, or local background, as Dr. Talcott Parsons emphasized at last year's Congress.

Of course, there have been scores of other significant changes involving people: the public has become increasingly mobile, smaller families are in vogue, there is a trend toward early marriages, and there are new demands and needs for goods and services. Time does not permit me to dwell on these or any of the other meaningful social and economic changes. But I think we will agree that these changes are affecting, and will affect, medical practice.

On top of all this, the changes in medical science have been exceedingly dramatic. And the outlook is for even greater changes. As Dr. W. Barry Wood has said, today's medical scientist is probing "directly at the very secrets of life itself."

Equally as impressive as this depth of medical science is the growth in breadth. Modern medical science today encompasses all of the basic natural sciences. It involves the social sciences and the environmental factors of illness. It can truly be said that modern medicine is borrowing more each year from the sciences and humanities on all sides. Thus, we can expect that this depth and breadth in medical science will produce impressive aids for the control of disease in the decades ahead.

Having taken a quick glance at the wondrous changes in our population, social and economic matters, and medical science, how will, or should, all this affect the future of medicine and medical practice? How must we respond to these changes if we are to fulfill our obligation of providing the best possible health care to the public?

Medical Responses to Change

Here are a few effects and medical responses as I see them: First, more people, higher incomes, more health insurance, better standards of living, and higher education will increase the demand for medical service. To meet this demand we must insure the American people of an adequate supply of physicians not only in 1960 but also in 1970, 1980, and 2000.

For the past 25 years or more the output of our medical schools has kept pace with our population growth. Now, however, we cannot continue to be complacent over past or present accomplishments. We must look ahead, in the light of social, economic, and population changes, to any deficiencies, shortages, or new needs which can be anticipated in the future.

We accept the responsibilities for providing an adequate supply of physicians in the future, as we always have, and as a profession dedicated to public service we certainly have no intention of limiting the supply of physicians—even if we had such powers.

Second, the profession must insure the quality of physicians being produced. I believe that physicians should be liberally educated men and women, as well as being properly trained in medicine, so that they can fit their activities appropriately into the social and economic culture of their environment.

President, American Medical Association.

Read as the Walter Bierring Lecture before the Federation of State Medical Boards, Chicago, Feb. 9, 1959.

Certainly, graduates must be well trained in medicine. However, because of medicine's complexity, no physician can be an expert in all of medicine; his expertness will be limited to a fraction of the vast field. This does not mean the physician should have merely a superficial knowledge of medicine outside his chosen specialty—and I include general practice under that term "specialty." Quite the contrary, all physicians should have good training in all phases of medicine. Thus, they will be able to handle an array of problems and will know where and how to get answers when they are unable to solve certain medical problems.

I also think that quality in a new physician must include a good deal of the art as well as the science of medicine. Certainly, as we are confronted with a larger and more mobile population and an increasingly complex and frustrating world, new physicians must be ready, willing, and able to assume more responsibility for the well-being of their patients. Medical science has progressed to a great degree, but the need and the demand for physician responsibility and for the discharge of this responsibility with warmth and compassion has not been eliminated and never will be.

Third, the patterns of medical practice must be modified, as necessary, to make practitioners productive and effective in meeting the needs of today and tomorrow. I believe that we can make a big start in this area by giving more responsibility to other legitimate personnel in the health field, personnel now doing much that legally is deemed medical practice. Already we are depending more and more on the techniques and skills of paramedical professional persons; at the last count there were more than 62 such groups.

We need the ideas and the assistance of these persons if medicine is to provide the best possible health care for the public. Like us, they take pride in their work of service, and I believe that our profession must respect them and emphasize the dignity of their calling. By exerting cooperative leadership with, not dictating to, these professional persons, medical practice can gain new dimensions as we seek to prevent, diagnose, and treat disease together.

I also believe that a realistic approach to the economic aspects of medical practice must be taken, recognizing the change that has taken place and trying to work out adjustments to future change. Medical men must work cooperatively with others, I think, or have others superimpose a way of medical life that may give medicine little voice. Certainly it is unwise to expend our energies fighting battles already lost. Rather, we should always contend with present and future issues.

Currently, the American Medical Association is taking several positive steps involving the economic aspects of medical practice and medical care. Two months ago in Minneapolis the House of Delegates took a major stride in helping to solve medical and socioeconomic problems arising from a rapidly expanding aged population. By unanimous action the A. M. A. House of Delegates approved a proposal calling for physicians to provide medical services at adjusted rates to persons over 65 years of age with reduced incomes and modest resources.

The proposal asked insurance companies and organizations with prepayment plans to develop new policies at special low premium rates for those over 65 years of age who are in the low income brackets. The House of Delegates also urged that the A. M. A., the constituent and component medical societies, and physicians everywhere expedite the development of this plan. This is one example of concrete, positive action taken in behalf of providing the best possible health care for the aged at a cost that senior citizens can reasonably afford.

The medical profession and various medical societies also are experimenting with advisory fee lists to guide physicians as to the propriety of their charges. In addition, these lists are providing the insurer with essential data that are basic to the design and underwriting of adequate sound insurance.

Another example of medicine's concern in this area is the work done by the A. M. A.'s Commission on Medical Care Plans. One of the important recommendations by the Commission is that "the medical profession assume a judicious, tolerant, and progressive attitude toward developments in the medical care field. The need for continued experimentation is recognized, and the profession should undertake, and actively participate in, the study and development of various mechanisms for the provision of medical care of high quality." The Commission's report represents a sincere and intelligent approach to medicine's necessary adjustment to the changing world, and I have every trust that it will be approved by the House of Delegates in June.

These are just three of the realistic approaches being taken to the economic aspects of medical care and practice. They demonstrate that the pace of American medicine's response to new problems and new challenges in the dynamic world of medical care and medical practice is accelerating.

I also believe that the profession is alert to the continuing need for the family physician not only to render continuing medical care in a definitive sense but also to see that specialists' services are used wisely. Most physicians realize that a profession composed of only "true" specialists would be wasteful of time, money, and effort and would not result in uniformly good care.

We in the profession see an increasing need for the family physician who can assume comprehensive and continuing responsibility, commensurate with his professional competence, for the patient or his family. This physician must have a special concern for the problem of the "whole patient," particularly the different "lives" he lives such as at home and on the job. Moreover, he must coordinate specialty consultation and care according to the requirements of the particular patient.

It is medicine's responsibility to insist that all physicians are competent for the medical service they undertake. Likewise, the profession must be willing and ready to discipline its members when and where there are instances of professional incompetence, no matter whether these involve family physicians or specialists. These, then, are some of the responses that the medical profession as a whole must make in fulfilling its responsibilities in this changing world.

Specific Responsibilities

As a federation, I believe that you have certain specific responsibilities in helping the profession provide the best possible health care for the American people. Let me enumerate a few of these. Because one of the major characteristcs of population change is real and increasing mobility, physician movement must be encouraged if the needs of a shifting populace are to be served. Therefore, there is a need for the extension of a uniform policy of endorsement or reciprocity of medical licenses. Also, with high standards of clinical clerkships being attained by most medical schools, it seems inevitable that the future of the internship—as now known—is questionable. However, there also is general agreement that one year of hospital experience beyond medical school is not adequate preparation for medical practice of either a general or a specialty nature.

Therefore, I believe that state boards should begin to consider modifying their requirements. Laws, rules, and regulations should allow freedom for sound experimentation in the medical school curriculum. I believe that the natural result would be an expression of confidence in our medical school faculties, and this could best be reflected by requiring only that students be graduates of approved medical schools in the United States or Canada. (The program of the Education Council for Foreign Medical Graduates promises an equitable approach to graduates of other countries coming to the United States.)

The boards should also explore with medical educators and others the feasibility and desirability of requiring a minimum of two years of approved hospital training after medical school before the physician is eligible for full licensure. Frankly, I am not certain whether this should be a legal requirement or a voluntary matter, as is internship in many states at the moment. In any case, there no longer exists good reason for spelling out the detailed nature of hospital training, for, it seems to me, it would be more realistic and effective to leave this to those institutions and agencies most directly concerned with educational methods and standards.

Moreover, years of experience have indicated that the quality of medical care rendered will not be uniformly of the high standard that the public has every right to expect without some definite stimulus to insure that all practicing physicians regularly keep abreast of important developments in medicine. Here are some of the many possible forms that this stimulus could take: 1. It could be a requirement of licensing that holders of licenses must at intervals demonstrate (through reexamination) that they have retained important basic knowledge and competencies and have kept up to significant advances. 2. It could be a requirement of licensing boards that holders of their licenses regularly participate in acceptable programs of continuing medical education. The developing activities of the Council on Medical Education and Hospitals in the postgraduate field should make this approach feasible in the near future. 3. This stimulus could be made a nongovernmental function by making reexamination, postgraduate education, or both requirements for continuing membership in organized medicine and specialty and other medical associations. This idea would broaden the kind of function now performed by the American Academy of General Practice.

I am not at all certain which of these methods is best. The first (reexamination) would produce the quickest result, but there is no assurance that it is best. This is a matter for careful study by all concerned, and it seems a logical function of the federation to pursue actively this study in cooperation with other medical groups that are interested and share this concern.

I do not offer this latter suggestion as something to consider, say, in 1965, 1975, or some later date. I strongly believe that the public and the profession must be assured now of the high standards and qualifications of physicians. Somehow this must be accomplished if medicine is to live up to its full responsibilities in this changing world.

Let me assure this federation that the A. M. A.'s Council on Medical Education and Hospitals is and will be interested in pursuing with you jointly all these matters concerning continuing education, reexamination, a minimum of two years of approved hospital training, curriculum experimentation, and requirements for medical school graduates.

To me the title of doctor of medicine has always meant obligation and responsibility. In this present era of rapid change and development, men of medicine must look at themselves and their profession with searching eyes and a critical mind. If we are willing to do this and are ready to take all positive steps that are necessary, we will fulfill the pledge of our profession to the public to attain the best possible medical care for the American people.

1836 South Ave.

WHY THIS CONFERENCE?

Leland S. McKittrick, M.D., Brookline, Mass.

The breadth and increasing complexity of medicine have made it necessary for the physician to concentrate his efforts in certain limited areas for purposes of study and teaching and for the clinical application of what we already know and are now learning. It is through the intensive efforts of various groups working in special fields at the research and clinical levels that the amazing developments of the past two decades have been possible—developments the magnitude of which no one could possibly have foreseen when the first specialty board (ophthalmology) was organized in 1917 to (1) elevate the standards of ophthalmology, (2) determine the competence of ophthalmologists who desire certification, (3) conduct examinations for candidates who appear before the board and issue certificates to those who pass, and (4) act as advisors to prospective students in ophthalmology.

From the expressed purposes of those who founded the board it would seem almost certain that they expected to establish ophthalmology more firmly as a special field of endeavor, to establish minimum standards, and to place an official stamp of approval on those who were able, by examination, to show evidence that they had acquired the necessary educational and practical experience.

Although this small group recognized the importance of establishing definite educational standards for the practice of a specialty, no one of them could possibly have foreseen the importance of this step in the preparation for, as well as the practice of, the specialty. Nor was this recognized in other areas until the 1930's. During this decade widening interest resulted in the rapid development of 13 new specialty boards. In 1933 the Council on Medical Education and Hospitals was authorized by the House of Delegates of the American Medical Association to "express its approval of such special examining boards as conform to the standards of administration formulated by the Council." Within a year the Advisory Board for Medical Specialties was organized. There are now 18 recognized specialty boards and, in addition, the American Board of Thoracic Surgery, which is organized within the framework of the American Board of Surgery. Since the several areas of clinical specialization are still without board status, the end may not yet be in sight.

These boards have not developed according to any preconceived plan or pattern. Specialty boards are approved by the Council on Medical Education and Hospitals after study and recommendation by the Advisory Board for Medical Specialties. Each board, for practical purposes, then becomes autonomous. Each may conduct its own affairs with little regard to the over-all developments in medical education and medical practice. Nevertheless, because of them our research has been more rewarding, our teaching at the graduate and undergraduate levels has improved, and those patients for whom specialty care has been available have benefited greatly. Board certification has assumed a position of importance—in government, hospitals, and educational circles—neither foreseen nor desired by the most ardent supporters of the boards. Even the evil heads of medical economics and philosophies of medical practice have been raised.

Our own interest is primarily in the broader aspect of education. Will the best interests of education continue to be served by further fragmentation of study of the human body and its ailments with the resulting rigid and, at times, uncorrelated departmentalization within our larger areas of medicine and surgery? I doubt that anyone would suggest that we discontinue our training programs aiming toward certification in general surgery and, instead, develop one surgeon to do hysterectomies, another to do supradiaphragmatic repair of the hiatal hernia, another to remove carcinoma of the intestine, and still another to resect the aortic aneurysm. Yet the development of specialty training programs, each with its own resident staff, is making it increasingly difficult to maintain good training programs in general surgery in many of our best hospitals.

In recent years I, as a surgeon, have tried, without success, to reorient in my own mind the relationship between the surgical specialties and general surgery. Is a surgical specialty an area within the broad base of surgery in which special knowledge is acquired and training in the special techniques obtained in lieu of a better understanding of the broader physiological, pathological, and technical aspects of general surgery; or should certification by a surgical specialty board designate the acquisition of special knowledge and special techniques over and above those of the general surgeon? Is it this latter concept of a surgical specialty that prompted the founders of the Board of Thoracic Surgery to require certification by the Board of Surgery before becoming eligible for examination by their own board? Thinking again in relation to my own specialty, I have asked myself if the rebirth of Wertheim's operation for cancer of the cervix and the development of pelvic exenteration for late can-

---

Chairman, Council on Medical Education and Hospitals, American Medical Association.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

cer of the female genital organs represent advances within the special techniques of obstetrics and gynecology or if they are only examples of the extraordinary developments in the broader field of general surgery. Is knowledge of the technique of total cystectomy with internal kidney drainage and an understanding of the early postoperative complications which may follow more closely allied to the problems of abdominal surgery or to those of the genitourinary tract? To put it concisely, considering the developments of the past decade, both in special fields and in surgery in its broader sense, is it easier to make a good specialist out of a well-trained surgeon or a good surgeon out of a well-trained specialist? I raise these questions in a spirit of complete understanding of our debt to the specialty boards for their invaluable contributions to medical research, teaching, and patient care—not in a spirit of criticism. I do suggest, however, that the developments in all fields of medicine since the organization of the boards have been so rapid and of such magnitude that the time has come when medicine as a whole and its specialty groups should carefully reevaluate the effects of our newly acquired knowledge on specialization and its relation to the parent disciplines and to our future educational programs.

1180 Beacon St. (46).

WHY THIS CONFERENCE?

Ernest L. Stebbins, M.D., Baltimore

The Advisory Board for Medical Specialties was established 25 years ago. There was, at that time, a growing concern because of the degree of specialization in medicine resulting from rapid advances in medical science and technology. The purpose of the board was to provide a mechanism for continuing study of some of the problems of specialism and to encourage and maintain standards of graduate education and training in those fields of medical practice in which highly specialized knowledge and skills are required. At the time the board was established, there were four organized specialty boards concerned with educational standards which offered examinations to test competency of specialists in these four medical specialties.

In 1958 there were 18 specialty boards represented on the Advisory Board for Medical Specialties, and these boards examined candidates and issued certificates in 51 different specialties or subspecialties of medicine. The proportion of licensed physicians certified by the American boards has more than doubled in the past 10 years. This increase in specialism is perhaps most obvious in medicine, but it is not peculiar to medicine. There has been a similar trend toward specialism in almost every phase of professional, scientific, and technological activity.

Reason for Trend Toward Specialism

The reasons for this trend toward specialism are many. The most obvious is what has been called the "explosive" rate of technological change and the increasing complexity of the whole range of scientific endeavor. This explosive increase in knowledge is directly related to an increased recognition of the value of research and discovery. The wartime development of research in nuclear physics served as a demonstration of the tremendous potential of organized and systematic study of unsolved problems. The impact of this demonstration is seen in the striking increase in support for medical research in the postwar period. The results of this acceleration in an already rapidly developing scientific field have been greater demands for education and training and inevitably greater specialization.

A less obvious, perhaps, but none the less important factor in the increase in specialism is the natural human drive toward excellence. The satisfactions derived from superior accomplishment are a powerful incentive, even though this may mean a restriction of the field of activity. The extent to which this restriction of the field may be necessary is related to the length of time necessary to acquire the special knowledge and skills. It has been estimated that a lifetime would not be long enough to acquire a high degree of competence in even a fraction of existing medical specialties. Consequently, specialism has tended to concentrate on

---

President, Advisory Board for Medical Specialties.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

highly technical skills, organ systems, groups of diseases, parts of the human body, or segments of the population. Other less admirable reasons for specialism include the greater material rewards frequently offered and the social prestige associated with at least some of the medical specialties.

Impact of Specialism on Medical Education

The impact of the trend toward specialism on medical education has been profound. There is some evidence of the influence of this trend to specialism on undergraduate medical education, but it is particularly felt in graduate education and training. The specialty boards, with few exceptions, require that every applicant for certification shall have completed from two to five years of formal and approved graduate education and training in the field in which they wish to be certified.

The Council on Medical Education and Hospitals of the American Medical Association, working closely with the specialty boards, reviews the quality of the educational programs in hospitals or other institutions providing specialty training. In 1934, when the Advisory Board for the Medical Specialties was established, the Council listed 377 approved hospitals offering 2,373 approveesidencies. In 1958, 1,248 approved hospitals red 5,300 approved residency programs providi opportunities for specialty training for approxitely 31,000 physicians preparing for examinati and certification in one or another of the recaized specialties of medicine. Residency trainig has become a rapidly increasing and more an more important component of the total program o medical education in the United States.

This tremendous increase in specialism in medcine has raised many questions. Is the trend towd more and greater specialization in the best intes. of the patient and of the physician? Does it pr vent or interfere with the necessary continuity an personalization of the care of the patient? A there serious economic consequences to both th patient and the physician? Has specialism, or mo specifically the specialty boards, had an undue i fluence on graduate medical education throug rigid requirements which must be followed in or to achieve the coveted certification? These a questions which seem to deserve the se thoughtful consideration of the medical p and those interested in the improvement o care in the United States.

THE RISE OF SPECIALISM IN MODERN SOCIETY

Paul M. Gross, Ph.D., Durham, N. C.

I am honored to be asked to present the initial background paper at this 55th Congress on Medical Education and Licensure, the broad subject for discussion of which is "specialism in medicine." Nevertheless, I must begin by warning that I am somewhat at odds in my thinking with some of the implications of the title which has been assigned to me, that of "the rise of specialism in modern society."

History of Specialism

If the methods of modern quantitative sociology were applicable and if the historic source materials were available, I strongly suspect that it could be demonstrated that "specialism" has always been an accompaniment and even an essential element of organized societies, especially those which were as highly urbanized as our own. Indeed, this has been done, in some measure, by such archeologists as V. Gordon Childe and others, who place the beg nings of specialization as far back as Neolithic ti in the early history of man's development.

Faced with the bewildering complexity of o own social structure, its profusion of impleme machines, instruments, devices, gadgets, and pecialisms, we are prone to think the latter are har acteristic of our time. Anyone who has visite Museum of Egyptian Antiquities in Cairo anc the high state of development of household an fine arts in such exhibits as those of the Tutankl amen tomb (1350 B. C.) must realize this civil zation had its full quota of specialists of all kind These must have included not only highly deve oped specialties among artisans and craftsmen bu a professional type of specialization in architectu and engineering. All evidence points to a simil high degree of development of specialism in household arts, agriculture, and the fine arts. one must speak with caution of the "rise" o cialism in our times. It has been a continuing le ponent of civilization, at least in historic times.

Vice-president, Duke University.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

Wh other aspects of specialism in our society
we w it today? How many specialisms are
ere ir social structure? It is easy to find listed
ne to five hundred of these if one looks in
h ace as a guide to allowable income tax
ucts related to one's job. Actually, there prob-
s many more again if we include the more
ecialties, such as those of abbot, through
ur and dowser, to zitherist. Are we all
, and what do we think of specialization
our own? Do we not all in some measure
ith Shaw's statement in the "Doctors Di-
that "All professions are conspiracies against
ity"? Indeed, we may ask whether there is any
n denominator or "common man" of the
" brand. Are we not in reality confronted
plex social structure with a "lack of
is is at least in some measure the case,
be one of our grounds for suspicion and
bout the growth of specialism in all lines
avor. We may ask if this is a characteristic
r modern society and in a measure unique to it
o our times. Again the answer appears to be
ive. The thoughtful citizen of the great ancient
polis of Rome with a population of about
,000 persons in the second century A. D. must
been confronted with some of the same ques-
we are discussing today. The highly organized
ation of the Roman Empire must have re-
d a great degree of specialism among its
nry to sustain its roads, aqueducts, commerce
food supply, logistics of the support of its
s, and the government of its far-flung colonies
provinces—not to speak of the high state of
opment of the fine arts and literature of its age.
us it appears clear that elaborate specialism, at
somewhat comparable in scope to ours, has
a constant and prominent ingredient of all
civilizations and especially of those which
highly urbanized. If this gives us a correct
ical perspective on specialism in modern so-
we must look elsewhere for the concern about
aspect of our society's organization which
to conferences of the type of this one. It
rs that our search for an understanding of this
rn must take at least two directions.

The Nature of Specialism

e first of these relates to the very nature of
alization itself. Particularly in the realm of
ectual endeavor the intense concentration of
son on a limited special area of knowledge and
tainment of expertness and competence in this
tends to break the broad pattern of uniformity
over-all social structure, especially in a demo-
system such as ours. This degree of separation
ven isolation of the person from the broad
m of the common affairs of man may lead to
iness in the mind of the average citizen. I am
ll of us share this feeling in some measure when we consider the specialisms followed by others, though of course we always except those in which we are, ourselves, engaged.

Numerous examples of this situation could be cited. One of the most obvious is the broad reaction in the body politic to the economic ideas and influence of the economic advisors to the "new deal" school of thought under Roosevelt. The uneasiness is often greatly aggravated by the habit of specialists to develop and use an entirely new nomenclature and terminology in describing and discussing their specialty. The one-time vogue of the word technocracy well illustrates the point at hand. These comments would appear to be valid in relation to specialization in any area of human endeavor, whether in science and technology, in the labor structure, or in the arts. The existence of highly differentiated specialisms is bound to present a certain divisive element, which, at times, may be characterized as subversive, in the broad fabric of the social structure. Thus, in public opinion, the discoveries of the nuclear physicists and chemists leading to the release of nuclear energy were, and still are to some degree, thought to be an area in the search for new knowledge better left unexplored. Such thinking was obviously not confined to the common man and the general public, if we recall the controversy among scientists, themselves, as to whether investigations leading to the development of the hydrogen thermonuclear reaction and the hydrogen bomb should be undertaken at all. This reached high places in the scientific hierarchy and was one of the crucial elements involved in the Oppenheimer loyalty investigation. This particular situation pointedly brings out one of the difficulties of specialism, namely, that the eminent specialist highly qualified in his own field is often regarded as competent and expert in the broader problems of human endeavor. All too often this is not the case. As Sir Arthur Conan Doyle, in "His Last Bow," described one of his super sleuths, "All other men are specialists but his specialism is omniscience." Here, then, is one of the dangers and one of the reasons for concern about specialism—not specialization per se or the attainment of great competence by the specialist in his field but the public's tendency to assume that such expertness provides sound ground, and even a type of omniscience, in dealing with the broader problems of human affairs.

Specialism in Science

The second direction in the search for the origin of our concern with specialism in modern society relates to the emerging scientific specialism. I have no competence to judge whether this applies to other areas than the sciences, so my discussion will be confined to the changing nature of scientific and technical specialization as we see it today.

ckground, we need to consider the modern opments in science, itself, to show their signifi-ce for specialism in our society. To understand he picture clearly we must differentiate between two broad kinds of specialization. The first of these, while it exists in large measure in our present society is not new but has had the same components throughout history. This can best be described in terms of the high degree of skill and intimate knowledge that the artisan, craftsman, artist, or workman in a special area can and does attain through long practice, deliberate development of skill, and wide and increasing acquaintance with the material and function of his specialization. It is best characterized by speaking of the art involved in his specialism. The competence of specialists of this type has constituted, and still does, the backbone of much of our working civilization and of its basic needs, as well as luxuries and enjoyment. In other words, high competence in the development of arts and crafts of our time has brought us to the rich level of civilization which we enjoy, whether or not we endow the experts in these fields and the fields, themselves, with the dignity of professionalism. Such growth will continue to be effective in the further development of the arts and crafts and even in much of our technology.

To this continuing and ever-growing stream of specialization, a new and important element was added beginning about the middle of the last century. This was the methodology of research and development as we use it today. From its limited effect in the last century, this broad technique has, by the middle of this century, become the most important single influence in scientific, technical, and industrial areas that affects our rapidly changing civilization. To understand this and its significance for the concept of specialism, particularly in tech-ical areas, requires a review of the changes in science during the past century.

This is not the place to develop these in detail, nor is there need to do so for this audience. Suffice it to say that from the early days of the alchemist to the opening of this century, scientific activity grew at an increasing rate and its importance and relation to economic development was greater with each passing decade. Nevertheless, the scientist, and especially the so-called pure scientist, continued to be a little-known member of society who worked in relative isolation in his "ivory tower" laboratory—commonly on some university campus. During, between, and after the two wars, a new scale of scientific and technological activity emerged. One of the first and most striking points of impact of this new activity was in the area of military affairs. The war gases of World War I, the development of air transportation and the great air forces, rockets, and the proximity fuse of World War II, were part of a trend to the highly scientific warfare techniques of today. The capstone to this trend was the development of the nuclear bombs, of nuclear propulsion in the Nautilus, and of missiles and the orbiting satellites.

Of equal and even of greater significance was the impact of this new technique of research and development on industry, commerce, and the entire economic structure. Old industries were revitalized or fell by the wayside; entire new and often giant corporate enterprises based on new products emerged, as in the electronics industry. Old ones, such as the food industry, were completely changed through new packaging and marketing techniques. The basic know-how for these changes came rapidly in a span of some quarter of a century through the widespread establishment and application of industrial research and development laboratories and their techniques throughout much of industry. What was literally a new type of industrial revolution was an accomplished fact by the middle of this century.

This is an old story to most of us here. What is not so well realized or so often understood is the enormous effect of these changes and of these new developments on the broad discipline of science itself. The rapid growth of the ranks of the scientific population and their spread and diversification, the new facilities, instruments, and techniques available, and the realization of the power and importance of well-organized collaborative effort have had the significance of a fourth dimension in scientific thinking and activity. As a consequence, there is new imagination, boldness, and scope in scientific planning and execution. This is well exemplified by the world-wide scientific enterprise we know as the International Geophysical Year. Here for the first time is a full-scale concerted effort in both time and space to understand the nature of the earth's environments—weather, climate, atmosphere, land, and oceans—and to analyze the hail of outer space radiation, luminous, thermal, ionic, and nuclear, to which this planet and its life are constantly subjected. Further, it is important to understand that this new effort is multidirectional. Global studies and the reach to outer space are spectacular but no more bold or imaginative and probably less significant for human affairs than the probing in depth of the chemist and physicist within the atom and the nucleus or of the biologist and biochemist within the cell and the genes.

So much for the renaissance in science, but what of its implications for this discussion of specialism? One thing seems clear and can be pointed up by an old saying which many of you must have heard. This is the description of the attributes of a specialist (usually a scientist) in comparison with those of a salesman:

"A salesman is one who begins by knowing a little about everything and who goes on learning less and less about more and more until he ends up knowing practically nothing about everything." On the other hand, "A specialist is one who starts off knowing a great deal about very little and goes on learning more and more about less and less until he ends up knowing practically everything about nothing."

The first description we can ignore for our present purposes. The second, in spite of its nonsense-lyric flavor, will bear more scrutiny in terms of this discussion. The trouble here is the lay conception that what is restricted or limited is simple and in its limits amounts to "nothing." Here is one cue to the problem of specialism, particularly in science, and to the lay public's understanding of it. As scientists we should not lose our perspective but recall the history of our discipline and remember that it has survived through pestilence, wars, and disasters and surmounted the barriers of race, language, and religion. It is indeed well to recall in this gray period of cold war with its iron curtains that the human race throughout its long history and evolution has had one common opponent: inscrutable nature, nature with her seemingly inexorable laws, her hosts of organisms and parasites, hurricanes, and catastrophic events of flood, earthquake, and epidemic. For our human race the central problem still remains to understand nature and control it. Scientists are privileged, as the lay public is not, to appreciate the great accomplishment of the truly great specialist with his fascinating glimpses of things to come, as the ramparts of our incomprehension of nature are breached from time to time by a "break-through." These ramparts are formidable in their complexity, and it is rare that they succumb to an attack along a broad front and then only in the hands of a genius—and geniuses are rare in the human race.

Justification for Specialism

Here then is the basic justification for specialism in science. The fundamental, over-all problem confronting us, that of a better understanding of nature, is immensely complex and involved. Only by concentrated, competent, and enlightened attack at numerous limited areas as they open up to us through investigation can we ever hope to begin to understand the whole. By this token one can confidently predict that true specialism in science will continue to survive and multiply.

This confidence is further strengthened as we look ahead in the light of the past. In science, much of our concern and achievement of a successful understanding has been in relation to inanimate things or parts of things or with relatively simpler organisms or functions within organisms. We must not forget that we, ourselves, are part of the great fabric of "nature." As our investigations and growing knowledge permit us to move more surely to such studies as some branches of human behavior and its physiological, genetic, and other bases, we can envisage new coalitions between neuroanatomists, neurophysiologists, and psychologists. T will, in turn, develop as specialties and may ev be dignified with the designation of professions or even disciplines, as in the case of present-day biochemistry and biophysics.

Facing this prospect, alarming to many of us, let us look at the negative aspects of such a further development of specialization and post some warnings. Specialization in the historic and classic context is here to stay; we can do nothing about it. The type of specialization arising from the renaissance in scientific thinking and operation will have a profound impact on the growth and character of science. Here the danger is that the form will be mistaken for the substance. To illustrate and at the same time not to draw invidious comparisons, let us imagine some future specialism, which, for want of better term, we will call neurobehaviorism. On what will its worth and validity as a contributor to our knowledge and as a field of endeavor depend? In the first instance, it depends on how well the workers in its field are based in the fundamentals of the derivative sciences of neuroanatomy, neurophysiology, and neurobiochemistry. Of as much or even greater importance would be how well they understood, or could acquire understanding of, those relevant and applicable principles from the basic, underlying sciences of mathematics, physics, chemistry, biology, and psychology.

In other words, the criterion of the worth and validity of an area of specialism in the sense outlined here is how solid and clear the pathways are from the outer branch to the deep and firm roots of available knowledge. An episode which Prof. Perry Miller relates about Ralph Waldo Emerson in the late 1830's at Harvard is to the point here. At that time, the then-young naturalist philosopher Henry Thoreau was an intimate of the Emerson household. One day he sat quietly in a corner while Emerson expounded to English visitors, "At Harvard college they teach all branches of learning." Thoreau then embarrassed his patron by blurting out, "Yes, but none of the roots." Unless there is vital and continuing sustenance from strong roots the branches of specialism will bear meager fruit.

Since this conference includes, as it should, discussions of medical education and research, it is appropriate to allude at least briefly to some of the implications that may be seen for scientific training in general and medical training in particular. Here one consideration seems paramount, and Thoreau's comment carries deep wisdom. Our effort in all scientific education should be to lay soundly the important fundamentals and to inculcate the knowledge of how to reason and make application to the particulars. As scientific knowledge becomes more and more complex there is no hope for sound training, within the limitations of the human mind and capacity, but to follow this route. The experience of the great and small industrial research organizations in the past 25 years provides clear evidence to support this point of view. In the early days of their inception in the 1920's, the total number of engineers and scientists employed was well below 100,000. At that stage of their growth they talked often of trained dye chemists, textile chemists, refrigeration engineers, and others in recruiting new employees from educational institutions. Today, after this experience and with a scientist and engineer roster of some 750,000, they ask that the scientific educational institutions train such students in the fundamentals of mathematics, physics, chemistry, biology, and similar disciplines and that they try to teach the technique of application to a particular problem. While the problem of sound medical education is admittedly more complex, there is at least food for real thought in this experience.

In retrospect, it appears that this presentation, contrary to its own theme, has been an attempt to select what appear to be the few essentials of the situation with respect to specialism in modern society. Such generalization has its obvious pitfalls. Perhaps it can be best characterized in the phraseology of Dean Wilburt C. Davison of Duke University Medical School. In the preface to his book "The Compleat Pediatrician," which copies the format of Izaak Walton's "The Compleat Angler," he says: "In contrast to many pediatric books which too often resemble the old-fashioned hoop-skirt in covering the subject without touching it, this book is like a G-string in touching the subject without any pretense of covering it, or even more aptly, like a brassiere in only touching the high spots. In other words, this book attempts to present the bare facts."

It is hoped that this discussion has pointed up some of the "bare facts" and high spots of specialism in our society and of their origins and that it will serve as a useful backdrop for the further detailed sessions of this congress.

SPECIALIZATION AND THE PURSUIT OF EXCELLENCE

Moody E. Prior, Ph.D., Evanston, Ill.

To what extent is specialization compatible with the pursuit of excellence? This is the question implicit in the association of these two ideas in our title. And since we are living in a civilization which requires and cultivates a higher degree of specialization than any in the past, we are also asking by implication whether our civilization is compatible with the pursuit and attainment of excellence.

Problems of Excellence

It is safe to assume general agreement on the proposition that the attainment of excellence is the proper end in the cultivation and use of our faculties, just as health is the proper condition of our bodies. Among normal people a serious disregard of health is felt to be irresponsible and the deliberate committing of acts which must destroy health is regarded as abnormal. We have somewhat the same feelings about people who misuse their faculties, fail to cultivate their talents, and are slovenly about their human powers and special abilities. We normally respect the person who attempts to maximize his powers and to realize fully his special talents and even to cultivate style and elegance in his use of them. "If our virtues did not go forth of us," says the Duke in "Measure for Measure," " 'twere all alike as if we had them not."

The comparison with health is suggestive not only where the analogy applies but also where it does not. In its ideal condition, health requires neither awareness nor deliberate effort. The healthiest object in nature is an active child who is unaware that he is healthy. It is only during illness or when the optimum state is past that we become aware of health and cultivate an interest in improving or maintaining it. With our faculties and powers the case is different. Even in skills, such as walking, which seem instinctively prompted, their mastery requires conscious effort, imitation, and improvement. The use of our faculties has to be learned. Moreover, we must practice and cultivate habits for their correct use, and, even after we have learned some skill, we must occasionally review its status and correct our lapses or try to conform to better models. This applies not only to manual skills but to such skills as speech and the proper use of our intellectual faculties. We usually take it for granted that we can speak and reason, but to refine these abilities we study the principles of

grammar, rhetoric, and logic and we acquire such sophisticated tools as scientific method. Excellence has to be acquired.

There is another difference. Health is indivisible; it is total. The satirist Swift pointed out that the reason we talk so much about illness is that it has many fascinating variant forms, whereas health, like goodness, is a single state and does not therefore provide so many interesting topics to talk about. Excellence is unlike health in that it is of particulars. It is concerned with particular skills associated with particular human powers and faculties. Since these have to be trained and their appropriate skills learned and mastered, there can be no total excellence. We admire the command of language of a writer, the fine physical coordination of the athlete, the virtuosity of the musician, the experimental brilliance of the scientist. But we find that these various forms of excellence do not exist simultaneously in all people. Versatile people are rare, and their versatility is, in any case, limited to a few things. Even within a particular area, the range of excellence is circumscribed. We do not normally find combined in one person the original composer and the fine tenor, the outstanding tennis player and the outstanding football linesman, the great writer and the great actor, the astronomer and the biologist. The conclusion is, I think, inescapable: excellence demands specialization.

It would appear that we have resolved the question with which we started. Not completely, however. Although our conclusions so far are not likely to be challenged, there exists at the same time a universal suspicion that the excessive development of any single facet can have a deforming effect on the person. The ideals and models of human development which have been admired and recommended by great civilizations in the past have invariably emphasized the harmonious development of the whole man, and this prototype still appeals to us today. We share the universal awareness that, like many good things, specialization has its abnormal and perverse manifestations, but in our time this realization is rendered urgent and acute because the technological standard of our civilization and the learning on which it depends require an unprecedented degree of specialization and it appears that we are compelled to risk its worst evils and abnormalities in order to secure the advantages of specialization—the existence and well-being of our society. The normal word of caution about the dangers of undue concentration on a limited area of skill and expertness has accordingly assumed the proportions of an elaborate critical apparatus. Our graduate and professional schools are criticized for turning out narrowly trained men, and specialism is attacked with seriousness and asperity and, sometimes, with a note of impatience similar to that which colors writing on the subject of teen-age mores and juvenile delinquency.

Problems of Specialization

In order to preserve a sense of proportion it is important to bear in mind that there are inherent defects which can appear even when specialization is pursued with the best of motives, the desire to excel and to become proficient in some useful art or science. Any such effort requires a degree of technical mastery and expertness. This skill is not the end but the means. But as long as one is clumsy or uncertain about the means he cannot make the best use of his talents and direct them to their proper ends. As long, for instance, as a musician is not master of his technique, he cannot put his mind to the meaning he is trying to get out of the score. Only when technique is largely a matter of habit and can be disregarded is one in the best position to exploit his art or profession or trust himself to attempt innovations. For the beginner, however, the mastery of the means is a difficult and absorbing matter and virtuosity becomes the immediate goal and sometimes the end itself. Often he is encouraged in his confusion. Virtuosity and extensive knowledge are widely admired, and they have a legitimate appeal of their own. We learned from the quiz shows that large numbers of persons stand in awe of anyone who has accurate answers to tough questions over a wide range of topics. And most of us experience exhilaration at witnessing a hard technical feat performed with apparent ease—the sense of difficulty overcome, as Wordsworth put it. I have noticed in dance performances that the applause often comes not when a beautiful effect is realized but when something difficult is done repeatedly, even though at times the stunt looks painful or ludicrous.

The striving for technical perfection or for total knowledge within a particular field of learning is admirable, but it is also the beginning of pedantry when these become ends in themselves and are divorced from their true purpose and the proper consequences of their use. Pedantry in learning has always been an easy and favorite mark for the satirist. Swift, writing in solemn irony, remarks that, as distinguished from superficial learning, true wisdom is like a hen "whose cackling we must value, because it is attended with an egg," and like a cheese "whereof to a judicious palate, the maggots are best," and, lastly, like a nut "which unless you choose with judgment, may cost you a tooth, and pay you nothing but a worm." But there is a pedantry in things other than learning; there is also a pedantry in skills, virtuosity, and expertness.

In an indulgent mood, we can regard the display of expertness and learning for their own sake as harmless. It elicits applause, and it might prove useful sometimes. But we should temper our indulgence when we reflect that it is always a human error when the means and ends are confused, and sometimes it is not harmless. The expert is not happy unless he uses his expertness, especially when his skill wins him applause, and the narrower the skill the more compulsive is the need to use it. If there are no occasions, he makes them. This accounts for our nervousness when the military gets hold of a fine new weapon. Often the exercise of a skill becomes a ritual act. We are familiar with the phenomenon of fashions in medicine. I suspect that they are often the compulsive and ritual manifestations of a useful knowledge or skill. Not too many years ago it was regarded bad practice not to extract any tooth that was devitalized or even suspect. During the same era the slop pail became the destiny of many a tonsil which today would be treated with more respect. Fortunately, the compulsive and ritual exercise of expertness is often self-correcting, since it tends to go too far for its own good. And there are always the maverick, the genius, and the skeptic in the new generation to set things straight again. In the meantime, however, the quest for excellence is perverted. Finally, the repetitive exercise of skill and the routine application of even an impressive body of knowledge tend to block originality. Hence the paradox that, although the full concentration of our powers on a proper end is difficult until the mastery of the means becomes almost a matter of habit, the expert who has come to depend on the habitual exercise of his specialty is unlikely to innovate—except by accident, when he needs to have all the luck on his side.

These various deformities of the quest for excellence are inherent in the nature of specialization in the same way that each possible form of government has its obverse side, so that, as Aristotle pointed out, monarchy can become tyranny, oligarchy bureaucracy, and democracy rule by demagogue and mob. Every civilization has therefore had to recognize the detrimental side-effects of specialization, since specialization is a necessity of civilization. Primitive man does everything for himself. It is only when functions become differentiated that arts develop, mastery over environment increases, and thought and leisure are possible. From this point of view no civilization can be compared with our own. In consequence, the accompanying vices of specialization are potentially increased, for as knowledge becomes more exact and practice becomes more effective the number of specialists increases. This subdividing has affected even apparently simple crafts (I have been informed that among expert tailors a coatmaker would not undertake to make a pair of pants), but when we come to the various advanced sciences and technologies the subdividing becomes formidable. It was once possible to speak simply of physicists, biologists, and physicians. I recall the lettering on windows of comfortable-looking houses and small office buildings: Dr. Blank, Physician and Surgeon. Within a few decades all this has been changed. At the dedication of the Midwest Library Center a few years ago, one of the visiting librarians was introduced to a distinguished scientist who was described as a mathematical biophysicist. The librarian was annoyed. "Why," he said, "can't you fellows stay within the system of classification established by the Library of Congress?"

This librarian, however, is in a dwindling minority. The public admires specialists. The professions admire them. The so-called generalists are out of fashion if not out of date. Occasionally we do them homage, as though recognizing an impossible ideal for old time's sake. Now and again the medical profession will single out a general practitioner toward the close of an honorable career and give him public honors, but there is something sentimental and nostalgic about this gesture. It is as though there had been introduced the practice of honoring the knight of the year during the late Middle Ages after the invention of gunpowder and firearms. Fundamentally, our instincts are right. We respect the man who tries within the short limits of a lifetime and the demands of an important field of activity to take all knowledge to be his province, but we are at the same time aware that, the more knowledgeable and effective a profession becomes, the more refined are its means, the more exacting its demands, and the more likely its drift toward increasing specialization. As primitive man is a generalist and takes care of all his own needs, the practitioner in the primitive stages of a science or profession encompasses all the parts and skills of his chosen field. As the profession advances, its parts are differentiated.

This process of differentiation in all branches of learning and in all professions has proceeded at an incredible rate during the last few decades. If we have come to pay tribute and do homage to the specialist it is because we recognize him as an absolute necessity in the advanced state of our technological success and the magnificent complexity of our civilization. He is our high priest. But we have not, at the same time, neutralized any of the endemic diseases of specialization; we have only multiplied the chances that they will occur and increased the possibility that when they do occur they may be harmful. Moreover, because the power and prestige of specialization have been widely acknowledged, specialists become increasingly concerned about status. They are jealous not only of the position of their profession in society but of their position and their rights and privileges in their own profession. (There has never been a jurisdictional strike in medicine, but there is no theoretical reason why there should not be.) And as specialties multiply and narrow in range, while simultaneously their prestige increases, it becomes easier for ignorance to conceal itself in technique and pedantry to parade as art.

The acute stage which our civilization has reached in experiencing the practical, social, and psychological problems of specialization is in large part a function of the state of learning in our times. The magnitude of our research activity is appalling, and so is the rate of its flow into the mainstream of learning. The record of the activities of our culture comes close to being total. Every scrap of official data is preserved; every research effort, including Ph.D. theses, is published. The stream of knowledge is a resounding cataract. To cope with it properly one has to select a limited area; to keep up with its course has become an unremitting and exhausting task. Moreover, the state of learning has become so advanced that the extreme boundaries are accessible only to the fully equipped explorers. This is true even outside the sciences. The exact understanding of such writings as the poems of T. S. Eliot or "Finnegans Wake" is no more for the casual amateur reader than is the proper understanding of Einstein.

A surprising and sobering fact about our culture is that, while its total knowledge is vast and of extraordinary refinement and the potential for more—and more recondite—knowledge is apparently inexhaustible, the area of individual ignorance is becoming correspondingly greater. As knowledge in every area increases and as the number of areas in which exact knowledge is possible multiplies, the individual's chances of knowing what there is to be known are radically reduced. This axiom applies not only to the man outside a particular field of learning but also to one in it. Every notable advance in physics, for example, renders not only the nonphysicist more ignorant but also the average physicist as well. In every science we will find good men who modestly concede that concerning some significant phase of their subject they do not know enough to have an educated opinion. We are in a better position than any before us to realize that the pursuit of excellence demands specialization and that the pursuit of specialization creates problems.

Possible Solutions

What solution is there, if any, for this age-old yet characteristically modern dilemma? There are pessimistic answers to that question, and if I had time enough I would enjoy the philosophic luxury of exploring them. However, the human animal being resourceful, its first impulse is to devise means for insuring its survival. In conformity with this normal and admirable instinct, I will try to suggest some possible ways of meeting the problems raised by the advanced state of our technical skills and the accelerating rate of our increase in knowledge. In doing this I shall try to keep in the foreground the special case of the medical profession.

The dangers and limitations inherent in excessive specialization can have more serious consequences for the medical man than, for instance, the electronics expert, not simply because of their possible human consequences but for their professional and scientific consequences as well. In simple situations, the need for a particular specialist's ministrations may be obvious and beyond question, but often it is not and sometimes, even when it is, judgment is required to determine whether that is all that needs to be taken into account. The object of the medical specialist's attention is an individual man, and that means not only that the specialist is dealing with the most complicated of all biological machines but that he is dealing with a being who must make continuous difficult adjustments to an involved social environment and who is the product of a unique personal history. One of the most profound emotional consequences of illness is the patient's troubled and only partial awareness that he has become an isolated object, that he has somehow lost his status as a distinctive, active human being and has been reduced to a thing. The humiliation of the individual by means of ruthless force and brutality has an analogous effect. The compulsive and ritual use of a specialty and the attendant blindness to contingent factors neglects this important aspect of the problem and in doing so interferes with the possibilities of the medical art and science at its best. Good medical practitioners have always been aware in some measure of these aspects of the problem, and I would hazard the guess that one reason for the profound insistence on the moral responsibility of the physician and the appeal to his humanity is that by this means we can inculcate qualities which act as safeguards against the neglect of the total human being and the understanding this approach provides for the nature of illness and its proper care. There is nothing more admirable than the notable efforts of the medical profession to live up to the high moral and humanitarian ideals which have been traditional with it since antiquity. If I contend that the moral and humanitarian appeal is not enough, it is not because I am indifferent to ethical and humane considerations but because as specialties multiply there must be a corresponding increase in the inclination to treat the medical problem as limited and as essentially chemical, mechanical, and physiological and, in consequence, a concurrent inclination to become detached from the total individual human being whose misery is the object of attention. What I suggest, therefore, is that the proper human use of a specialty should be approached as a function not simply of the physician as a good man but of the specialist as a good physician.

There are two possible approaches to the correction of the defects and limitations of specialization as they apply to medicine. One is through the conditions, forms, customs, and organizations which exercise control over the practice of medicine; the other is through the ordering of medical education and training.

One promising development in the practice of medicine has been the increase in the use of teamwork, not merely in the great diagnostic clinics but among smaller groups of closely associated specialists. Moreover, the design and organization of a modern hospital has been shaped by a recognition of the contributions which a large number of skills may be required to make in a given case. To be sure, there is the danger that a patient may become an object in an assembly line and the further danger that divided responsibility may weaken the assumption of responsibility. But, at its best, the collaborative approach avoids the most conspicuous abuses of specialization; it preserves the value of a high degree of individual limited expertness and at the same time maintains a concern for the total human being. It is like a string quartet, in which the individual player demonstrates his own skill best by contributing to the harmony of the whole. There must be, I am sure, equally valuable developments of which I am not aware. The point I wish to illustrate is that dangers and imperfections which arise out of circumstances within a profession must in part at least be countered by establishing modes of association and activity which will reduce the chances of defect or abuse without demanding of each person an exhausting measure of moral and intellectual heroism.

The second approach to meeting the dangers of specialization must be through the training which produces the medical specialist. In the first place, since the outstanding phenomenon of our times is the appalling increase in knowledge, the aim of the training should be not the impossible one of providing for full detailed knowledge and complete experience in all the sciences and techniques that are relevant to medicine but on the basic concepts, the theoretical foundations, and the principles of method which give meaning to the vast data of the various sciences and which make possible their operation and advancement. Moreover, the subjects in the program of studies should be ordered to appear progressively related to one another, so that one step provides the key to the next and not merely the academic prerequisite for getting into medical school or the clinics. We can no longer afford to exhaust the memory, to waste time, to repeat uselessly.

We must also accustom the student from the beginning to the notion that science, in the narrow sense, is not all. On this point I wish to make clear that I am not now concerned with making cultured men out of medical specialists or providing them with outside interests to make them good citizens and with high-grade hobbies to render them less high-strung and more contented. (What do you suppose would have been the response of such men as Franklin and Jefferson to the question often asked of prominent men today: What is your hobby? Their lives seem to have been their hobbies.)

My concern is not with the relation of the medical man to his culture, his society, or his personal happiness, important as these matters are, but with his work as a practitioner and scholar in his field. If it is true that a consideration of the patient as a man in society and as a unique individual is relevant to medicine, we have one good reason for encouraging the medical specialist to temper his exclusive concern with the physical sciences and medical techniques with an interest in other sources of knowledge and wisdom about man. There is a second reason. Originality is not stimulated by narrowness; nevertheless, the specialist has become our chief hope to advance knowledge and improve practice. It has often been observed that progress in the arts and sciences sometimes seems to occur in unexpected jumps and leaps. Analogy is a notoriously undependable means for establishing truth, but I believe it is one of the potent means for promoting discovery and analogy operates best through the intuitive perception of identities in unlike items. The failure to see experience outside the schematism of a limited discipline, whatever it might happen to be, impoverishes the mind. The history of science is dotted with instances which suggest that unusual useful developments in the arts and sciences often originate from a stimulus outside the particular art or science itself.

We should consider it as a hopeful sign that there is so much current preoccupation with the need for broadness in education and so much criticism of narrowness and overspecialization, even though some of this criticism is a trifle hysterical and often ignores the fact that our civilization depends on specialists and that the advancement of learning requires specialization. Some educators, disturbed by the isolation and narrowness of the training programs for advanced specialists, prescribe heavy doses—within the limits of possible tolerance—of courses in subjects quite outside the course of study, sometimes completely remote from the area of specialization. This approach to the problem does not impress me, because it sometimes sounds punitive and self-righteous—like injunctions to take cold baths—and because it ignores the fact that after a certain point in a person's education it becomes increasingly difficult to repair the deficiencies of his past, especially by resorting to methods which are more suitable to the early stages of the educational process. By the time one has reached the final and most advanced stage in his formal training, his task has become too concentrated, his purpose too single-minded, to impose side excursions on him in the expectation that he will be taught a lesson which he should have learned long ago.

Besides, this approach to broadness in the advanced stage of the education of a specialist is an attack on the periphery and not at the center. At this stage, the heart of the matter is the way in which the specialty is taught. It is my impression that all too often the approach is too restricted. It is too often directed toward producing the clever technician and not the educated expert. Too often, the student's attitude is that at last he can settle down to the mastery of a limited and finite body of knowledge and a sharply defined skill. And too often his teachers do not disabuse him. Tennyson wrote a poem about a flower in a crannied wall which concludes, "If I could understand what you are, root and all, and all in all, I should know what God and man is." No doubt a trifle ambitious, but it illustrates the attitude I would wish to adopt in the teaching of any specialty. It has occurred to me, for instance, that if a student of literature really understood all that is involved in the word metaphor he would have to open his mind to many matters, including linguistics, epistemology, the history of criticism, the theory of poetry, and something more besides. And the same might be said for the young scientist who tried to understand all that is and has been implied and contained in the word atom or cell.

The Norse god Thor was once taunted by the giant Utgard-Loki into attempting various tests of strength and prowess. Among them, he was challenged to lift a cat. To his humiliation, Thor found that he could not budge the animal. It turned out that this was no ordinary cat. It was the exposed portion of the fabulous Midgard Serpent whose body encircled the earth. Trying to lift it, Thor had been straining to lift the entire world. I would hope that every advanced student could be made to understand that his specialty is Loki's cat, that what he sees of it above the surface may appear small and easily manageable but that in reality it is necessarily bound to the universe.

THE NATURAL HISTORY OF SPECIALISM IN MEDICINE

Iago Galdston, M.D., New York

Modern medicine and specialism are historically coextensive and all but synonymous. It is understandable, therefore, that the future of medicine is commonly envisaged in the patterns of the immediate past, that is, in the further development and refinement of specialization. Those so persuaded cite the specialties which seem to be springing up before our very eyes, such as enzymology, electrolytic dynamics, and nucleic acid fractionations. In a sort of furor of enthusiasm, they picture the future practice of medicine as an orchestration of virtuosos—each the master of some refined and esoteric department in the clinical score. This vision is enticing, even though it is unrealistic and unhistorical. Essentially, it is foveal in nature, that is, of a pinpoint character and unredeemed by peripheral orientation. It is an uncritical vision that fails to differentiate between the isolated minutiae of research, the extension and perfection of technological processes, and the holism of the practice of clinical medicine.

Unquestionably, research and technology are essential and contributory to the practice of medicine, but the latter is as much above and beyond them singly and collectively as are the creations of the poet and the painter above and beyond the grammarian's rules and the studied properties of pigments and their vehicles.

Without discounting in any sense whatsoever the import of specialization in research and medical technology, it is my intention to submit and to defend the thesis that the future of medicine lies in directions other than the further multiplication and refinement of medical, that is, clinical, specialism.

Whitehead said, "The last thing any science discerns is what it is all about." Medicine is not exactly facing "the last thing," but it is not amiss to try even now to discern what it is all about. To do this effectively, we must first take our bearings—keeping in mind that we are particularly concerned with specialism.

Historical Background

Our orientation needs to be historical, and, consulting the chronicles, we come on a most astonishing fact: specialism, which we are prone to consider a modern feature, was in effect most highly developed when medicine was in its infancy.

Herodotus relates that "besides dentists and oculists the Egyptians possessed doctors who treated diseases of the stomach only, diseases of the head only, and so of other parts of the body; indeed each physician treated only one disease." It is worth noting that in the land of the Nile medicine was completely socialized. Diodorus Siculo says that throughout Egypt the sick were treated without cost, all physicians being employed by the state. As was to be expected, physicians were required to use only the official remedies and in no case to resort

to others, unless the authorized prescriptions proved unavailing. Any transgression of this rule of practice, if followed by the death of the patient, was a *capital offense.*

Herodotus lived in the fifth century B. C. and thus was a contemporary of Hippocrates. In this connection we come to another interesting fact, namely, that in Greece there were no specialists. The learned medical historian Charles Daremberg affirmed in his essay, "Sur la division de la médecine" (from La Médecine, p. 454), that the Greek physicians did not even distinguish between the practices of surgery and medicine. "Between the founding of the Alexandrian and the Celsian schools, the most prominent practitioners were at one and the same time physicians and surgeons."

From this juxtaposition of "historical contrasts" in Egypt and in Greece, we can establish the conclusion that *even in its earliest stages medicine exhibited a bipolar trend, one directed toward pluralism and the other toward monism.* These were initially philosophical schools, but they had a profound effect on medicine—pluralism fostering specialism and monism advancing what in modern terminology would be described as the unitary or holistic view of medicine.

The ancient Greek physicians were not unaware of these conflicting trends. In the post-Hippocratic period, that is, between the time of the death of Hippocrates in 357 B.C. and that of Galen in the second century A.D., there came into being a variety of medical schools, each dedicated to the advancement of some singular phase of either the pluralistic or the monistic version of medicine. Thus there were the dogmatists, the empiricists, the methodists, and a host of minor variant schools.

To make sense out of their polemical conflicts is a difficult but not an impossible task, for what, in effect, troubled them was precisely what troubles us today, namely, how to interpret and relate the theory and practice of medicine to the data of human experience.

The monists, among whom we must count both Plato and Hippocrates, argued that the universe, and man within it, comprises a meaningful, integrated entirety which is governed by certain all-embracing principles, accessible to the penetrating intelligence of thinking man. The monists maintained that unless both man and his universe are comprehended in the framework of these embracing principles the crude data of sensation and the ever-current stream of experience can yield nothing but a bedlam of confusion.

In stark contrast to the monists the empiricists, taking Aristotle as their intellectual leader, rejected all speculative theories and dedicated themselves solely to the cure of disease. Their motto was "not to understand disease but remove it."

The issue of pluralism and monism was in some measure reconciled in Galen. Galen's "Treatise on Medical Experience" begins with the affirmation, "When I take as my standard the opinion held by the most skilful and wisest physicians and the best philosophers of the past I say: The art of healing was originally invented and discovered by logos in *conjunction with experience. And today also it can only be practiced excellently and done well by one who employs both of these methods."*

This is patently a noble and yet palpably a naive affirmation. For it takes experience for granted, as if experience were self-revealing, transparent, and intuitive to human intelligence. Hippocrates was not that naive. He knew that experience was deceptive and that its "deception" could not be laid bare by the unsophisticated logos. Something else was requisite, a philosophical orientation or, as it was later termed, "logos harnessed to a method."

The logos of man did not formulate this method in a definitive form before 1636. It was then that René Descartes published his "Discours de la méthode."

Descartes was not the only proponent of the thesis of this work. Among his precursors were Thomas Hobbes, Giordano Bruno, and Francis Bacon. This thesis, witnessed in the illuminating achievements of Descartes' contemporaries Galileo and Harvey, may be summed up as follows: to broach experience, not in its most complex but in its simplest and most elementary components; to explore these by the methods of experimentation, that is, by the artful structuring of experience for preconceived goals; and to mensurate the resulting information in quantifying terms, that is, mathematically.

This, as I am sure you must appreciate, is *essentially empiricism resurgent—but in a new* and novel form. It is pluralism *de novo* and specialism *in statu nascendi.*

Bacon and Descartes were philosophers rather than scientists, and yet their respective works served to discredit rather than to advance philosophy. Thereafter, among the learned, the scientists outnumbered the philosophers, and nature which to the Greeks was, in itself, simple was in time dismembered and parceled out among a host of "natural scientists," workers in special disciplines.

This brings us to the threshold of the 18th century, the age in which modern medicine was born. It was signaled in the final overthrow of Galen's authority. The assault on this authority began more than 150 years before, in the first half of the 16th century, with Paracelsus as its leader. It was consolidated in the "Fabrica" of Vesalius (1538) and in the "Motu Cordis" of Harvey (1628).

The foundation of modern medicine rests on the study of anatomy, the detailed and correct exposition of the structure of the human body. This pursuit, making common the practice of dissection and defining the norms of the body's organs, in time made possible the study of gross pathology. Autopsies, prosections to demonstrate the anatomic concomitants of disease, became commonplace. The science of pathological anatomy was founded on the monumental labors of Giovanni Battista Morgagni, whose "De sedibus et causis morborum per anatomen indagatis" was published in 1761. But note the title of Morgagni's work. It was not merely *de sedibus,* the seat, but also *de causis,* the causes of disease. This points to new developments, to the anatomically oriented nosology and nosography. The linking of symptoms to organic changes, and by indirection to altered function, could not but yield many refinements in diagnosis, prognosis, and therapy. Such was indeed the result. What began as gross pathology was advanced and developed by a host of ingenious men and yielded in time (but before Virchow established the science of cellular pathology) subtle and penetrating insight into the morbid processes of the diseases affecting the major systems. In this connection, Richard Bright, William Stokes, James Parkinson, John Cheyne, Theophile Laennec, and others, by their singular knowledge and expertness, became in effect the prototypes of the modern clinical specialist.

As the medical historian Arturo Castiglioni affirms, "At the end of the 17th century, when the cooperation of medicine and the natural sciences was being emphasized, we already see outlines of the essential features of the great structure of experimental science. Already various specialties began to be detached from the main trunk. . . . Here we have an extensive preparation for modern medicine."

Recently I wrote an analysis of the history of specialism entitled "The Birth and Death of Specialties." (*J. A. M. A.* 167:2056–2061 [Aug. 23] 1958). I will repeat but little of the argument presented there, for I would rather take a closer look at specialism itself and speculate on its future and the bearing it may have on medical education.

It is of interest that medical specialism was first pursued mainly by the laity. The lens coucher, tooth extractor, lithotomist, bone setter, midwife, masseur, and barber surgeon were the specialists of the middle ages and later. It is a significant archaism that in England the surgeon is addressed as "mister" rather than "doctor" and that it was said of John Hunter that "he made gentlemen out of surgeons." As can be gathered by this catalogue of specialists, they, the specialists, were the doers, the operators. They were, as so many are today, technicians, men skilled in crafts rather than knowledgeable in theories.

It is of interest, too, how much of specialization is dependent on instruments and instrumentation. Historically, many specialties were literally made possible only when the effective tool came to hand. The classic example is the ophthalmoscope. Another is the roentgen tube. It is not too much to postulate that the tool made the specialist no less than the specialist the tool.

Components of Medicine

Thus, in the broadest sense, medicine embraces two major components, a *gnosis* and a *techné. Gnosis* is medicine's knowledge and understanding of man as a living creature surrounded by many and varied realities. *Techné* embraces all the operational modalities used by the physician in his efforts to benefit man.

During the past 150 years, the *techné* of medicine has tended to overshadow and to outstrip its *gnosis,* even though the latter has grown immensely. This, I am persuaded, is the result of two contributing factors: the phenomenal growth of the technological sciences in general and the vast and ever increasing demand for what I term episodic medicine.

The practice of medicine, as I see it, is divisible into two major categories: episodic and maintenance. Episodic medicine, as the term implies, is the medicine practiced in emergency situations, best exemplified in the surgeon's work. Maintenance medicine is devoted to fostering the everyday well-being of the individual. It is best represented in the practices of the pediatrician and the nonspecialist internist.

Episodic medicine is primarily and predominantly the realm of the specialist, and he in turn is the master of medical *techné.* Maintenance medicine calls for less *techné* and for a deeper indoctrination in the *gnosis* of medicine.

Implicit in the above definition of *gnosis* are the monistic overtones of Hippocratic medicine, for I identify modern specialism with the pluralism of the empiricists. But specialism is not thereby disparaged. That were indeed a folly, if for no other reason than that, as I have indicated, present-day living is beset with numerous emergency episodes, not all of them surgical in character. My intention is not to belittle the *techné* of medicine but to plead for a better and wider comprehension of the *gnosis* of medicine, both among those who practice episodic and among those who practice maintenance medicine.

Today, however, all the emphasis is on *techné.* Even our undergraduates in medicine receive their instruction as a sequence of specialty parcels. In most medical schools the current curriculum is a recapitulation in four years of the historical development of medicine during the past 400 years. The result is that the graduate comes forth schooled in the thought that the practice of medicine consists of discovering what the patient has and what is good for it. A really basic comprehension of biology is rarely encountered. Chemistry, being a must, is fairly well known, but general physiology is not. Ask the young graduate to describe what effect exercise has on lymph circulation and tissue nutrition and to speculate on what bearing this may have on metabolism, and you are likely to have a blank stare for an answer. Ecology will most likely be a familiar term, but not its full significance to the understanding of the patient's history. Of medical history the young graduate is likely to be blissfully ignorant. To sum it up, in education, as in practice, the accent appears to be on *techné,* while the need is for *gnosis.*

Future of Specialism

I have said that specialism is here to stay, but not that it will stay the same. Specialism is, in effect, confronted by the challenge of its own technological instrumentalities. I cannot envision automation taking over the surgeon's work, but it may well take over that of his anesthetist. Certain it is that, increasingly, the diagnostic laboratories with their multiplicity of apparatus are taking over more of the tasks in the exercise of judgment and discrimination formerly performed by the specialists. I am also convinced that an even greater challenge to specialism lies in the deepening penetration of the physiological sciences into the mysteries of normal function. I need only call in witness the effects which the science of nutrition has had on a host of specialties.

Thus far I have treated of specialism as a phase of the growth and development of medical knowledge. But specialism has a social as well as a scientific aspect. There are, in other words, specialties and specialists, and the derivation of the practitioner-specialist may be "a thing apart" from the specialty he practices. Historically, the specialty, as a compact cluster of particular knowledge, antedated the advent of the practitioner-specialist. Laennec knew a great deal about chest diseases, but he was not a lung specialist. Richard Bright knew more than any of his contemporaries of the chronic disorders of the kidney, but he was not a urologist. William Stokes of Dublin wrote treatises both on diseases of the chest and on diseases of the heart and aorta, but he was first and foremost a clinician and not a specialist.

Granted there was not too much to be known in any of the specialty fields, so that any gifted and studious physician could be both expert in one department of medicine and competent in the rest. But that is precisely the point I wish to underscore. When, in the early stages of specialism, a physician became a specialist, he more than likely had come to his specialty through years of work and experience as a generalist. Such, of course, is not currently the case. Men set out to be specialists before they have completed their undergraduate training. Despite the seemingly reasonable plea that medical knowledge is too vast and too complex for any one mind to encompass it, and, hence, specialization is inescapable, I am persuaded that much specialization is motivated by less cogent and more worldly reasons. I would feel more reassured if I saw the neophyte specialist cramming himself to the limit of his capacity with the knowledge basic to a sound comprehension of medicine.

It is certain that the specialist has operated in what may be called a scarcity market. It is not likely to continue as such indefinitely. Specialism in its social and economic aspects must sooner or later come under the sway of social and economic determinants. It is likely to be less rewarding economically and to offer less prestige. This, too, may lead to a coalescence of some of the specialties into larger and more inclusive divisions of clinical medicine.

Though medicine has prospered enormously during the past 200 years, in an era of increased and refined specialization, one is not warranted in envisaging the future of medicine in a like perspective. I think rather that, while specialism will remain an important division of medical service, medical science per se and medical service perforce will undergo a revolutionary change. The change will be the result of the maturation of the knowledge and intelligence to be derived from the disciplines of physiology and ecology.

Ecology, I am certain, does not call for detailed definition. However, physiological medicine does; it is too easily confused with the physiology of the smoked drum variety. Physiological medicine is, in my definition, the operations of the organism set in its environment. Exemplary of physiological medicine is the magnificent discipline of nutrition—magnificent in the true sense of that term, "doing great deeds" or characterized by "greatness of achievement." To the credit of the science of nutrition stands the true conquest of pellagra, beriberi, rickets, scurvy, chlorosis, and a host of other disorders and diseases.

Within the ambit of physiological medicine lie a multitude of factors which are requisite to the optimal operations of the living organism. And there is, as you must perceive, a most intimate interrelationship between ecology and physiological medicine.

Conclusions

I have ventured some prognostications as to the future of medicine. These prognostications are neither as wild nor as hazardous as they may appear to be. It lies inherent in the developmental process of every science that after a period of wild and florid growth it matures into a consistent and meaningful discipline, compact in principle and pervasive in application. It is this I am sure Whitehead meant when he said that the last thing any science discerns is what it is all about.

Medicine has experienced 400 years of specialism, in the last 150 to a most intensive degree. We are now, I am persuaded, on the verge of that stage wherein the emergent unifying principles of the biological sciences, reflected notably in the disciplines of physiology and ecology, promise to make of medicine a consistent and meaningful discipline compact in principle and pervasive in application. This matured medicine, enriched in *gnosis*, will subserve and enlarge the operations of maintenance medicine and will correspondingly make less requisite those of episodic medicine. I respectfully submit that it would be well for those charged with the education and training of our future physicians to pay heed, to prepare, and to foster this promise of the future.

2 E. 103rd St. (29).

THE CHALLENGE OF SPECIALIZATION IN BASIC MEDICAL SCIENCE

S. Marsh Tenney, Hanover, N. H.

Successful scientific investigation has thrived with the motto "divide and conquer." Only by dividing and subdividing major problems into manageable parts has it been possible to obtain definitive data which, when interpreted, could be resynthesized to answer the original question. Overwhelming testimony provided by the history of science has affirmed this fundamental technique, but at the same time there has arisen a criticism broadly recognized as a limitation of general discovery which is apparantly the product of the classic strategy. We need only recall the trenchant analysis of Slawkenbergius' treatise on noses to sense the caricature of specialization in the public mind. The basic issue, then, is not whether specialization has been or will continue to be necessary to the advance of scientific knowledge but, rather, whether there is some feature implicit in the system which has been detrimental to the greater good.

Specialization Leads to Generalization

Whitehead has stated, "The subjects pursued for the sake of a general education are special subjects specially studied; and . . . one of the ways of encouraging general mental activity is to foster special devotion." We should expect, however, that specialized investigation not only would lead to a detailed and precise definition of a phenomenon but, by nature of its completeness, should be developed into profound general truths that stand antithetically to the rigid and restricted concept of "specialization." "The essence of knowledge is generalization" (Whitehead).

The boundaries between the subdivisions of science are artificial and should largely disappear as a deeper insight into fundamental phenomena is acquired. The sterile cul-de-sacs of research are not implicit in the method but are human—an unwillingness on the part of the investigator to interpret broadly and imaginatively. Who could label Claude Bernard a specialist on electrolytes? Yet it was through a detailed examination of these chemical minutiae that he formulated one of the few existing basic "laws" of biology, that the existence and constancy of the physicochemical properties of the body fluids is a necessary condition for the evolution of free and independent life. Quite clearly, there is a point in investigation where the vertical pursuit suddenly broadens into a wider understanding, and it is at this juncture that the gifted few find general expression for hitherto unknown relationships.

The question must be posed as to whether something has transformed the boldness of spirit which should be the heart of research into a timid reluctance to explain new observations outside conventional dogmas. Is there an increasing "lack of discrimination between the details which are now irrelevant and the main principles which urge forward human existence"? I believe that, unfortunately, both these questions must be answered in the affirmative and that the problems arise simultaneously with an attitude accompanying increasing specialization. There has resulted a changing pattern of specialization which is both the product of the times and an instrument in perpetuating its own weakest points.

One of the challenges of graduate education in the basic sciences is that of providing the student with sufficient familiarity in a variety of topics so that he can range effectively over accepted boundaries without the stigma of dilettantism yet be sufficiently well informed in at least one field to become expert in it. Many of the most exciting problems in modern biology and medicine lie in the "in-between" areas, and their solution is more likely to come from the man whose training and outlook are broad. I submit that both training and outlook are of equal importance.

The following apology quoted from the first paragraph of a recent scientific paper emphasizes the conservative scholar's preoccupation with the boundaries of his own range of knowledge. "It carries me out of my field, and off of ground on which I feel secure; it may prove again only that a little knowledge is a dangerous thing." Erasmus, sensing this problem long ago, offered the following advice suggesting that folly might constitute the necessary ingredient for a renaissance: "For there are two main obstacles to the knowledge of things, modesty that casts a mist before the understanding, and fear that, having fancied a danger, dissuades us from the attempt. But from these folly sufficiently frees us, and few there are that rightly understand of what great advantage it is to blush at nothing and attempt everything."

Medicine began to acquire stature as a science when, instead of knowledge appearing as a by-product of the solution of immediate problems, deliberate efforts were made toward the enlargement of knowledge by test cases selected toward that end. In general, the development was from common-sense knowledge, but its growth depended on

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

the assumption that there was more to know than the context admitted and that there were assured ways the unknown could be discovered. It has been said by Hawkins, "Nature is not directly amenable to the forms which an artist or scientist may choose or invent. Changes of style may open up new areas of subjects, or the concern with new subjects may force the development of new styles." One of the lasting tributes to the genius of the great classic figures in medical science is the skill they displayed for inventing not only new techniques but often whole new concepts in fields quite outside their own area of specialized interest when the solution of the problem at hand demanded it. They set an enviable record by their contributions to the sister sciences when the [illegible] could not be solved readily by the application of physical laws known at the time. Physics is richer for the *contribution of Helmholtz to the theory of sound*, for the precise experimental definition of the laws of fluid flow by Poiseuille, for a quantitative description of the elasticity of solids by Young, for the first statement of the first law of thermodynamics by Mayer. Even the founder of the *American Journal of Mineralogy*, Archibald Bruce, was a physician. There may have been humility, but the record would not suggest any timid reluctance on the part of these men to advance into areas far out of their field, work toward and arrive at a solution, then return with their new knowledge to the biological problem which stimulated their departure. But the climate has changed. It is almost unthinkable now that a medical scientist would dare to risk creative activity in any other area of the life sciences, let alone in the physical sciences. Indeed, there is even some reluctance to learn what is currently known in these disciplines, let alone what is unknown. Rather, the solution would seem now to be as simple as adding one more "specialist" in the personnel category of a research grant application and congratulating oneself not only that the "team" is nearing completion but also that medical educators will be satisfied the approach is "modern" because it shows evidence of "multidisciplinary integration."

In attempting to bridge the gaps created by established, specialized interests, one must be careful that a new specialty does not arise just to fill the gap. Such specialties start with a credo affirming virtue in breadth but quickly mature with horizons confined to the limits of the gap.

Biophysical Feedback

The biological scientist is struggling with increased vigor to learn and to apply to living systems knowledge from the physical and mathematical sciences. The importance of this association is widely recognized and appreciated, but the significance to the broader aspect of biological thought must not be lost from sight. Any direct imitation of the physical sciences must be accepted as a sign of immaturity. The 17th century was an instructive period, filled with enthusiasm for the conversion of medicine to chemistry and physics. The science of mechanics was in its heyday, and it contributed immensely to the understanding of the circulation recently discovered by Harvey. Still, the era ended with disillusion and a cry for the return to Nature. The balance had been lost—too much was expected to follow from imitation, a lesson confirmed by the failure of Linnaeus' attempt to classify diseases according to his scheme.

There is every confidence that living systems will be described ultimately in a mechanistic rationale, but it is also not unlikely that certain unique features in living systems will escape known concepts developed exclusively around phenomena of the inanimate world. There is a difference between *returning to the physical sciences for basic* concepts on the one hand and becoming slavishly dependent on the other. It is still likely that certain fundamental concepts in biology properly fed back into physics will provide suggestions of mutual advantage. This must have been what Sullivan, the mathematician and physicist, had in mind when he said: "The great intellectual conquests of the near future, the next great step forward in the development of human consciousness, may be expected to come from biology." For analytical purposes the parts and processes are legitimately treated in isolation and within the established concepts of physics and chemistry, but too often sight is lost of the fundamental role of organization in biology—that the unified whole is more than the sum of the parts—aptly put by Muller: "To say for example, that a man is made up of certain chemical elements is a satisfactory description only for those who intend to use him for fertilizer."

One of the great weaknesses in biology is its paucity of "laws." Even bad laws are useful, for they provide a framework on which to construct. Formalization is urgently needed, but imitative response is not enough. Unfortunately, biology has yet to find its Newton.

If we accept that the mental attributes of the contemporary scientist are equal to those of his ancestors, then there remain several factors which provide significant barriers to productive generalization. The enormous complexity of current scientific knowledge is a formidable obstacle, and no one would disagree that it is too much to hope that any mere mortal could master even a segment. In spite of this, it seems to me there is reason for optimism, for inevitably the final expression of great generalities tends to be disarmingly simple.

A second deterrent is one for which I feel specialization is directly culpable, although the vanity of man is a necessary ingredient. It may also be that the social structure which has bred "organization man" provides a milieu in which the inherent weaknesses of specialization flourish. A caste system in science is not new, but I believe that more recently there have increased two unfortunate products that weaken the basic goal of research. These are scientific snobbery and the establishment of cadres of secrecy. The former may be a part of the social constitution of man and the latter, in part, a consequence of poor communication because of the development of jargon, but both create an atmosphere in which worthy or relevant information can be considered to evolve only from the next "higher" science. The chemist G. N. Lewis has beautifully described the situation as follows: "The man whose chief apparatus is the differential equation looks down upon one who uses the galvanometer, and he in turn upon those who putter about with sticky and smelly things in test tubes. But all of these, and most biologists too, join together in their contempt for the pariah who, not through a glass darkly, but with keen unaided vision, observes the massing of a thundercloud on the horizon, the petal as it unfolds, or the swarming of a hive of bees. And yet sometimes I think that our laboratories are but little earth-works which men build about themselves, and whose puny tops too often conceal from view the Olympian heights; that we who work in these laboratories are but skilled artisans compared with the man who is able to observe, to draw accurate deductions from the world about him."

Charity and an appreciation for good science from all sources is less apparent. We need a realization that pedestrian physicochemical measurements on a blood protein are neither more sophisticated nor more fundamental to the advance of medical knowledge than an accurate description of a new syndrome arrived at through patient observation at the bedside. No one is so omniscient to foresee where the missing links for a rational description of the fundamental truths of life will appear. To avoid intellectual segregation is difficult at best, but to deprecate knowledge from any source, deliberately, betrays an unforgivable provincialism. Modern specialization, fostering security in a tight little compartment, tends to reduce the scientist to a petty role, but it is my contention that the destructive forces concerned are primarily social and psychological, not intellectual. The specialist becomes a sharp critic of those who threaten his domain, and the would-be pioneer tends to be recast as an intruder. Rather than risk derision for venturesomeness the specialist takes refuge in his own compartment—thus creating a self-perpetuating scheme.

Conclusions

An objective of graduate education in the basic medical sciences is to provide sufficient training in the physical and life sciences that the student can work competently and confidently with the concepts and techniques fundamental to a study of mechanisms of all life phenomena, irrespective of specialty. The challenge is to add to this an intensive period of study and investigation on a particular problem without sacrificing breadth of outlook. The attitude of his teachers is the single most important factor toward this end.

HAZARDS IN PLURAL BIRTH.—The chances of being born alive and of surviving the first year of life are distinctly less for children in plural births than for the single-born. Furthermore, the hazards are greater for triplets than for twins and greater for quadruplets than for triplets; the survival of a set of quadruplets is a rare event. Plural births account for only 2% of all births in the United States but are responsible for about 6% of the fetal deaths (still-births of 20 or more weeks of gestation) and for nearly 10% of all infant deaths. . . . The fetal death rate among twins in the United States in 1956 was 43.6 per 1,000 born alive or dying during the fetal period, compared with a rate of 15.6 per 1,000 for the single-born; for other plural deliveries the corresponding rate was 80.6. Data available for twins show a particularly high fetal mortality among those born to very young mothers and to mothers at ages 45 and over, but even those born to mothers in the age range 20-44 years experience a higher fetal death rate than the single-born. . . . Whether or not a mother has had children previously is also a factor in the mortality experience of infants born in plural sets. A recent study in Iowa showed that both the fetal mortality and the neonatal death rate (mortality in the first four weeks of life) generally decreased with increase in parity of the mother. . . . Deaths ascribed to prematurity account for about half of all neonatal deaths among children in plural births, a rate approximately 9 times that for single births. . . . Irrespective of birth weight, both fetal and neonatal death rates are higher for the second-born of a twin set than for the one born first. Much of the difference is attributable to the disparity in mortality from birth injuries and postnatal asphyxia. Identical twins experience somewhat higher neonatal death rates than fraternal twins.—Hazards in Plural Birth, *Statistical Bulletin of the Metropolitan Life Insurance Company*, November, 1958.

THE EFFECT OF SPECIALIZATION ON GRADUATE EDUCATION IN SURGERY

Herman E. Pearse, M.D., Rochester, N. Y.

Specialization is so widespread that it permeates every phase of our society and has resulted in many of the material and scientific advances in recent years. Only when specialization is premature or is dissociated from the whole does it have an adverse effect.[1] This is as true of the mechanic who tightens one bolt on an assembly line as it is of the physician who gazes into only one orifice of the body. Such restricted specialization permits a rapid acquisition of the skill necessary to perform the limited task, so there is no need for the laborious and time-consuming process of acquiring an understanding of its integration. In former years the position of a specialist was attained only by superior intellect and experience directing observation or experiment to increase medical knowledge. This authoritative position attracted students who came to learn from the master. In the United States Halsted[2] formalized this relationship by creating what we now call the residency system of training. Soon after, Mall implemented full-time clinical training.[3] These changes have had a profound effect on subsequent medical education.

Halsted and others fostered the development of special fields in surgery. This was accelerated by World War I, especially in the areas of orthopedic and plastic surgery. Soon after, the subspecialties of orthopedics, urology, neurosurgery, plastic surgery, otolaryngology, and ophthalmology were well developed, with residents in training, at Johns Hopkins University School of Medicine. Specialized residency training was initiated in other teaching institutions and expanded rapidly. After World War II it spread to many nonteaching hospitals so that specialization was put on a production line basis by establishment of credit for training and the award of a certificate. This rapid increase in specialists has made a great change in the practice of medicine.

There are many ways to explore the effects of increased specialization. It was decided to examine only the educational changes because the way special skills are acquired will influence how they are practiced. To make this study more specific it was limited to surgery, with our teaching hospital as an example, and it was restricted to the period 1927-1928 to 1957-1958, which is the period of my tenure at that institution.

The Strong Memorial Hospital, Rochester, N. Y., is owned and operated for teaching by the University of Rochester. When it opened in 1925, there were 246 beds, of which only 26 were for private patients. In 1936, a private floor of 14 beds was added and semiprivate patients were admitted to the wards with the understanding that they would be used for teaching. In 1941 a private wing was built, and in 1949 a psychiatric clinic was added. At present there are 257 semiprivate and ward, 128 private, and 74 psychiatric beds, a total of 459. The Rochester Municipal Hospital is owned by the city of Rochester but is operated by the university under contract. Its building is a part of the medical center, and the two hospitals are operated as one unit. In 1925, the Rochester Municipal Hospital had 209 beds, which were increased to 321 during the depression (1936) and now total 302. Thus, there are a total of 761 beds, excluding 41 bassinets, in the two hospitals which constitute the basic teaching unit of the medical school.

During the period after World War II so many of our men required completion of their training that it was necessary to use other clinical facilities. Experiments in assigning residents to "affiliated" hospitals were tried. Some of these hospitals were outside the city, in Clifton Springs, Ithaca, Canandaigua and Batavia, N. Y., and in Bradford, Pa. For various reasons all of these have been discontinued except for the Veterans Administration Hospital (257 beds) at Batavia, N. Y. At the same time affiliations were made with hospitals in Rochester, N. Y. These have now narrowed down to a cooperative, coordinated program for the first two years of "general training in surgery" with the Genesee Hospital (252 beds) and the Highland Hospital (242 beds), both of which are fully accredited, four-year, surgical training centers having their own interns and third-year and fourth-year residents. This pooling of clinical resources has given a broader experience than could be offered by any one of the hospitals alone. The combined bed capacity is 1,512, and experience is given in community, teaching, and government hospitals.

In subsequent discussion, the size of the resident staff at the Strong Memorial and Rochester Municipal hospitals is always given as a corrected figure which represents only the residents working in those two hospitals. Any men assigned elsewhere have been subtracted from the total. Data are tabulated by academic years beginning July 1, but for brevity the nomenclature for fiscal years is used. Thus, 1957-1958 becomes 1958.

During the 30 years covered in this study, profound changes have so altered graduate medical education that it has become increasingly difficult

for educators to achieve the level of competence which they desire for their students. Some of the factors which have caused these changes are more rigid definition of the specialties, the creation of certifying boards designed to evaluate competence but often dictating the educational experience leading to it, the increased regulation of teaching hospitals by medical and surgical societies, the impact of medical insurance which has depleted the wards of the teaching hospitals, and, finally, the disruption of education by two wars and obligatory military duty in peacetime. An effort will be made to analyze the effect of these on our teaching hospital.

Growth of Specialized Training

Many members of our original faculty had been at Johns Hopkins University, so it was natural that heads of each special division of surgery should be appointed. Specialization did not extend to the resident staff, for in the beginning the general surgical residents were responsible for all cases. This was not satisfactory to those in charge of the special divisions, for they wanted their own graduate students. In 1933, residents were appointed in the subspecialties of surgery, and since that time their number has steadily increased. This is shown in table 1 and illustrated in figure 1, where the part played by general surgery and the specialties is related to the total. This shows how the subspecialties were hit hard during the war and rebounded after it. But it is evident also that as the wave of postwar trainees began to subside it did not return to its former level due to the requirements of certifying boards. At first the cost of this increased staff was borne by veterans' benefits, but now it must be paid by the institution, which creates a heavy expense despite inadequate salaries.

It is desirable to relate these changes to activity or experience. This can be done by using bed capacity, admissions, or patient days, but in surgery operations performed is probably the best index. In figure 2 the increase in operations is plotted against the growth of the surgical resident staff. At the end of the war there were men from the classes of 1938 to 1945 who all returned at once to complete their training. This elevated the curve of resident staff above that for operations. Now, with the increase in specialty residents, this has recurred. If the operations performed are divided by the number of residents, a ratio of operations per resident is obtained which may be used as a general index of experience. This is shown in **figure 3**, where it is seen that this ratio was very high in the early days when the general surgical residents were responsible for all cases. It was 772:1 in 1930 when I was resident. This meant long hours and hard work but a golden opportunity for training. However, this situation was inadequate for the needs of the service, and a better balance was obtained when residents were appointed for the subspecialties. This dropped the ratio to about 300:1 where it remained until the war. Recently, it has dropped to 221:1 as more residents were added. It is difficult to evaluate what is required for a rewarding experience, and, certainly, no one factor can be used as a gauge. The minimum number of residents is easily arrived at because it is fixed by the board requirements of the various specialties. For example, if two, three, or four years of specialized training is stipulated then there must be two, three, or four men going up the ladder to the chief residency in these specialties. If general surgical training is required before specialization then there must be a man for every year specified. To these are added the number aiming at a career in general surgery, and by simple arith-

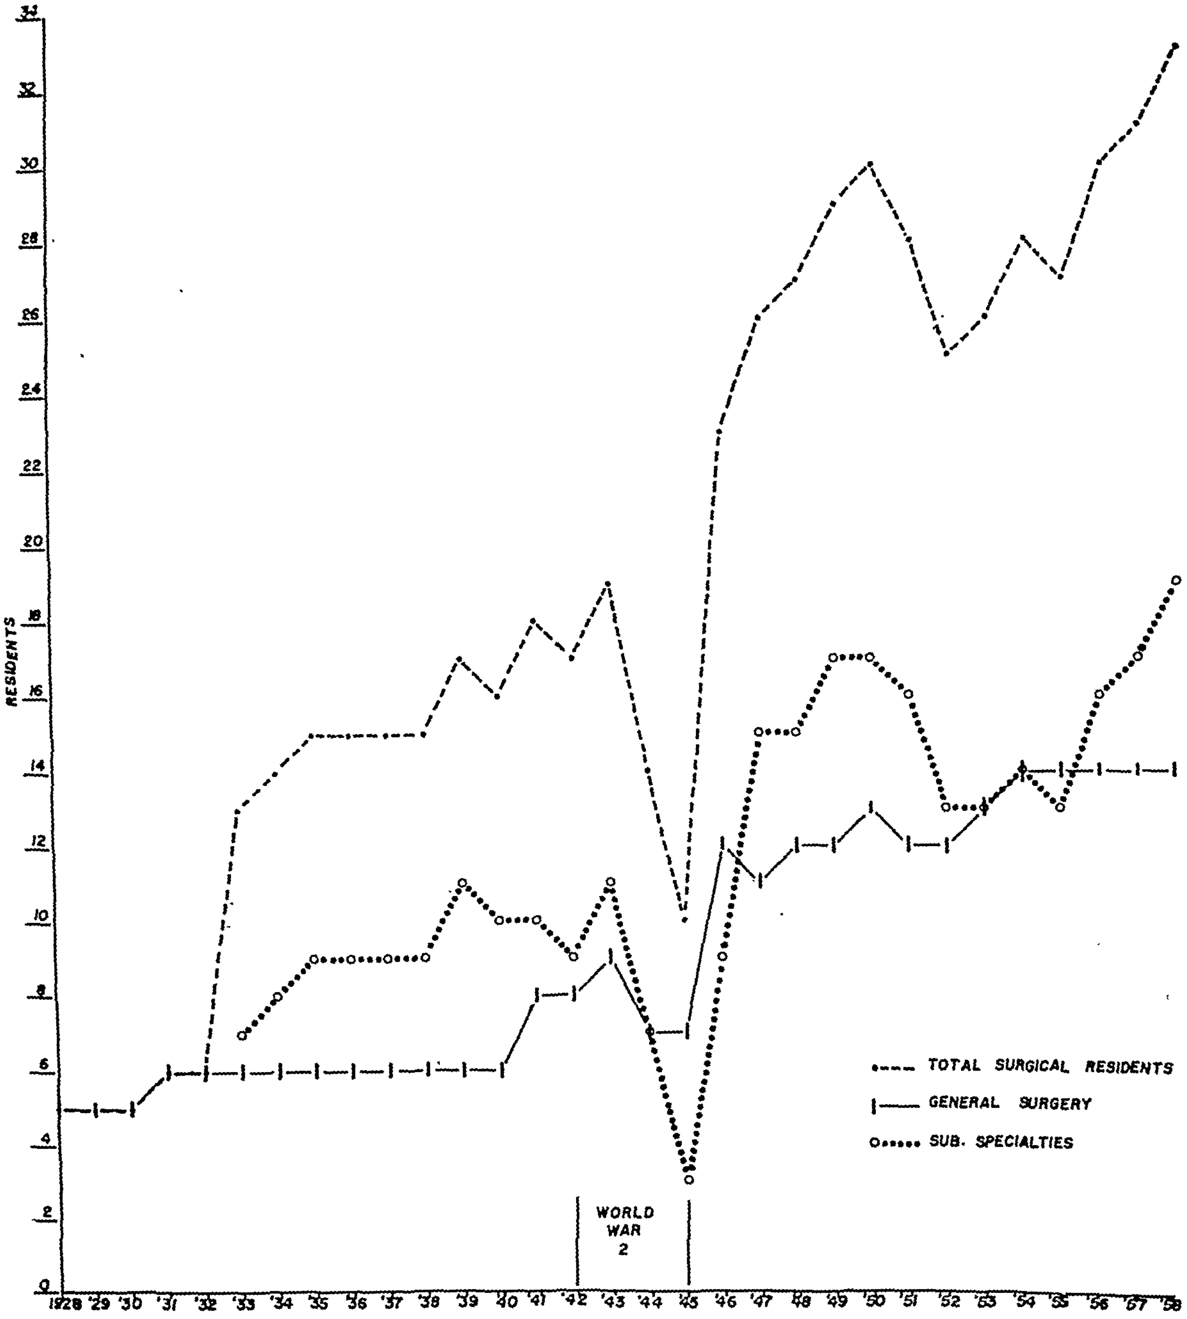

Fig. 1.—Growth of surgical resident staff at Strong Memorial Hospital, Rochester, N. Y., 1928-1958.

metic we arrive at a total. It should be emphasized that this is an educational, not a service, requirement, so it may bear little relation to clinical work load. Some insight is gained by a study of discharges (an index of patients treated), which is given in table 2, and for patient days (an index of bed occupancy), shown in table 3. That these reflect differences in the type of work load is apparent by comparison of the percentages in the two tables for otolaryngology and orthopedics.

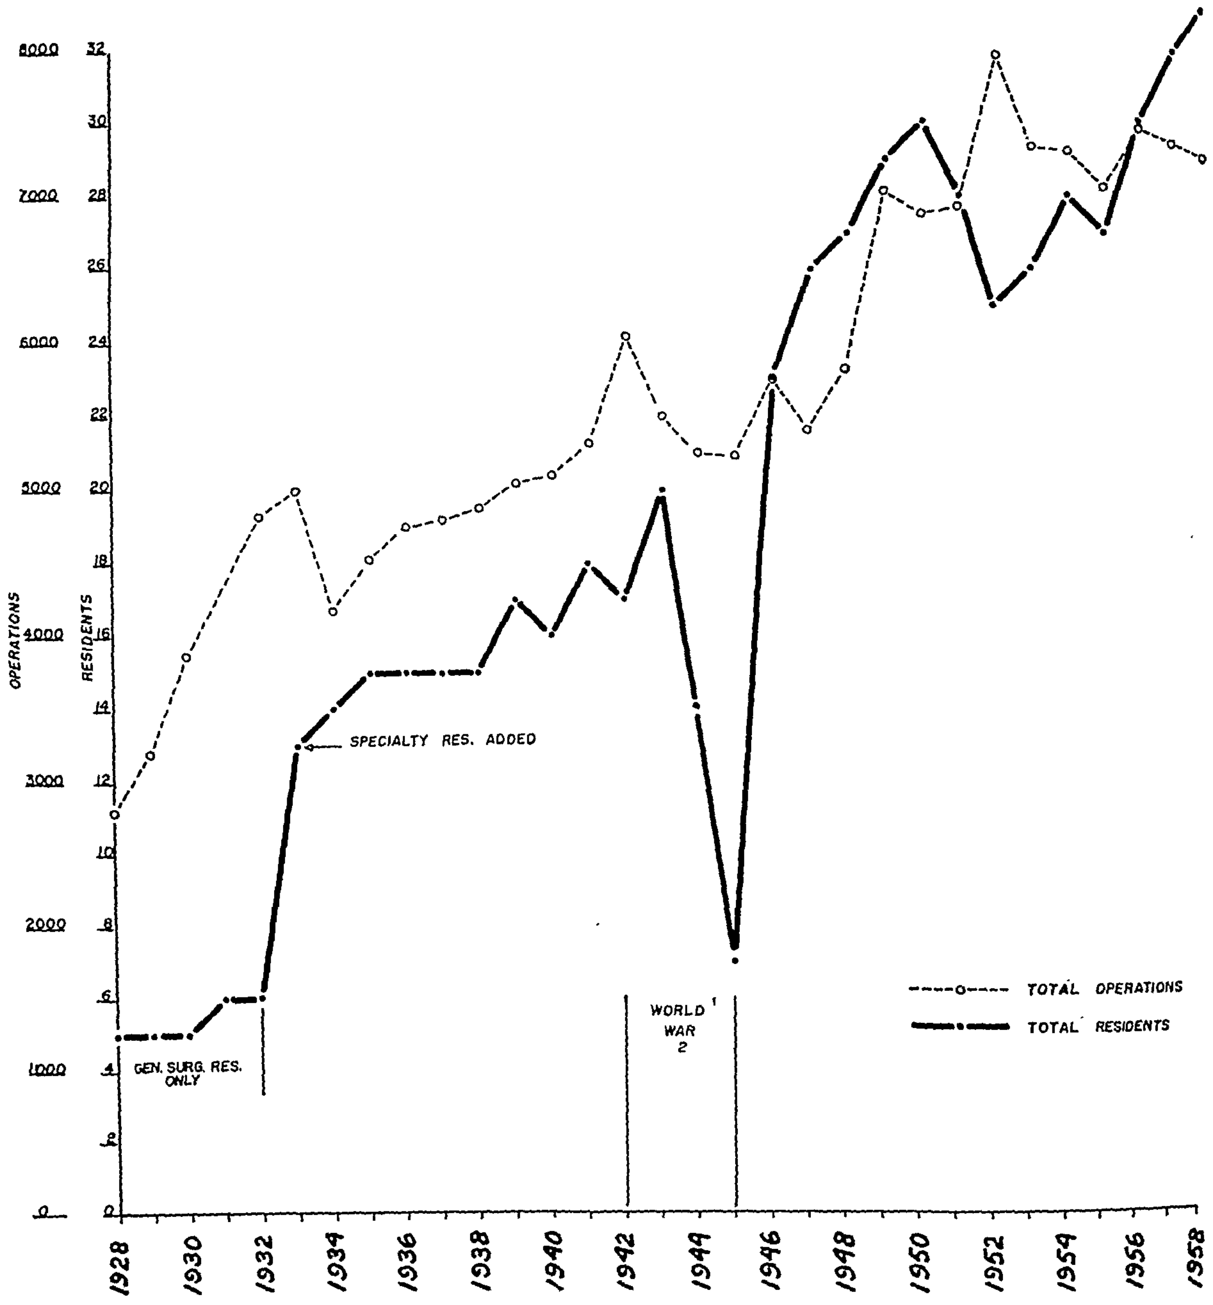

Fig. 2.—Relationship of increase in number of residents to operations performed at Strong Memorial Hospital, Rochester, N. Y., 1928-1958.

Increased Segregation of the Specialties

These figures give some insight into the growth of specialized training, but they fail to tell the whole story. The prewar subspecialty residents had extensive general training in surgery before they, alone, were in charge of their specialty. For example, in orthopedics four men had been senior or chief resident in general surgery prior to their appointment as orthopedic resident. There were few restrictive regulations, so that only proficiency in their field was the aim; with their surgical experience this was rapidly acquired. Patients of all specialties were admitted to the 32-bed wards which were designed with a four-bed cubicle as the largest unit. Interns were assigned in charge of these floors, with students as the clinical clerks. This gave a cohesive, smoothly functioning service for clinical care and teaching. But World War II changed that.

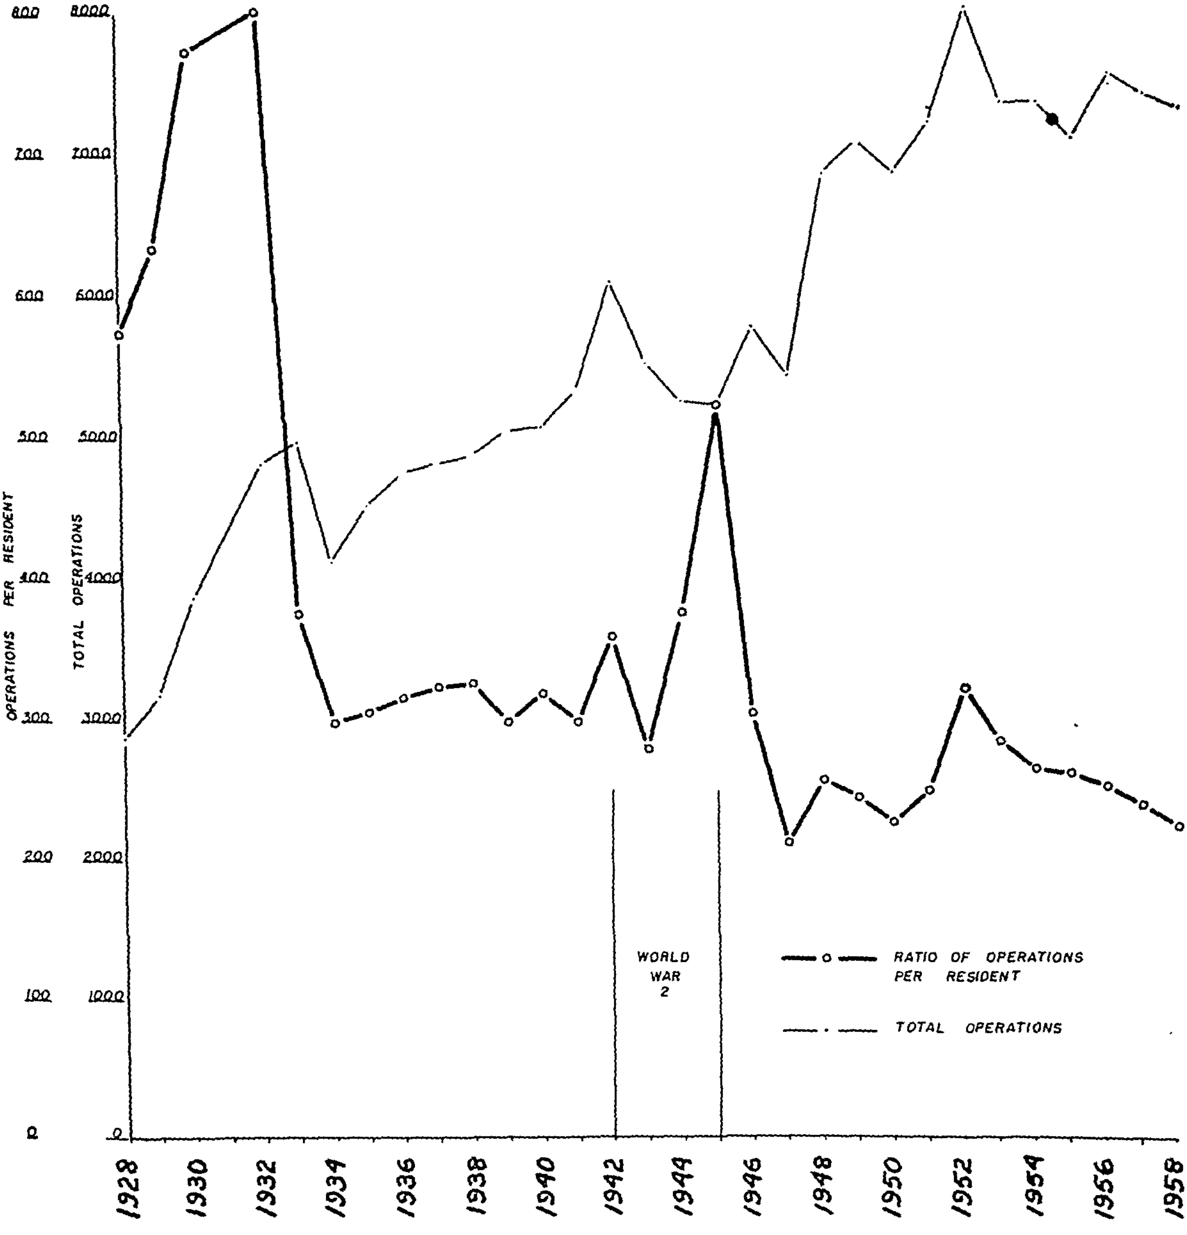

Fig. 3.—Ratio of operations per resident at Strong Memorial Hospital, Rochester, N. Y., 1928-1958.

The certifying boards were well established in the decade after 1930, but they had not assumed their present importance. The armed services chose to use board certification as the yardstick for specialized assignments which carried higher rank and more rapid promotion. Those who did not have certification observed this, and on their return they unanimously said "I want my boards." Meanwhile the boards defined residency training as the acceptable way to competence. Preceptorial training was largely abandoned. The period of subspecialty training was lengthened. This increased the number of specialty residents who formed a team and tended to restrict their activity and interest to their own field, splitting the service into several separate groups. But the interns and students were still assigned to the surgical floors where all patients were admitted. Now they had to deal with many more residents who were usually concerned with only a few of their patients. Sometimes a group of specialists would make rounds and find that the intern was not available and, therefore, would leave orders or initiate therapy. Multiply this by several specialty groups, and it is easy to see that the interns were often in a state of confusion about what was happening on their floors. It was obvious that the interns must also be assigned to the special services in order to become a part of their teams. This really isolated the students on the floors, for they were completely dissociated from the house staff, their most intimate teachers. So they also were assigned to the specialty services. With everyone concerned attached to special groups, there was better coordination of patient care and teaching but more compartmentation of the surgical service. The next logical step in this process is the separation of beds and operating room facilities, which will complete the segregation of the specialties.

Table 2.—*Discharges from Surgical Services, Strong Memorial–Rochester Municipal Hospitals, 1951-1958*

Surgical Service	1951-1952	1952-1953	1953-1954	1954-1955	1955-1956	1956-1957	1957-1958	Total No.	Total %
General	2,876	2,799	2,879	2,939	3,172	3,070	2,942	20,677	41.7

Eye	437	450	378	422	386	421	445	2,939	5.9
Plastic	317	321	302	357	375	360	417	2,449	5.0
Urology	806	835	803	816	880	810	706	5,656	11.4
Orthopedics	1,082	1,099	1,284	1,120	1,195	1,098	976	7,854	16.0

Few educators will advocate segregation and compartmentation of special areas of medical teaching. But all scientific, social, and economic trends are in the direction of specialization. The only way to resist is to ignore this, which would be out of step with the times. If specialized fields are taught, they must be taught well. To strengthen specialized teaching means appointing the best man obtainable to be in charge of the specialty, giving him associates, a budget, space, residents in training, and teaching time. If this is done, separate groups are created which splinter the field of surgery into compartments. The problem then becomes one of integrating these in patient care and teaching. This would be greatly helped if the certifying boards of the surgical specialties could agree on a period of general training in surgery which would include rotation through all specialties. Then at least all specialists would have some idea of what their colleagues were aiming at. But, in addition, experiments in coordinated medical care must be carried on in the teaching hospitals. For example, we are trying this in a "combined clinic" under the direction of the department of medicine but with all specialists available for cooperative management of the patient's problem. Such experimentation must be actively pursued if we are to find a way to avoid segregation of these many components in the face of separate interests and skills.

Regulation of Residency Training

The residency system of training was developed as a form of graduate surgical education. Halsted was intensely interested in extending the knowledge of surgery and so attracted superior graduate students. He shared with them his enthusiasm for research and improved clinical care. All the resources of the laboratory and clinic were at their disposal. After 1913, a full-time clinical staff was instituted, so there was less distraction from practice and the small attending staff was closely associated with the residents. This intellectually stimulating atmosphere developed outstanding surgeons, many of whom became eminent. The same type of environment was slow to spread. For example, in 1938, when the Society of University Surgeons was established with a condition of membership the stipulation that the candidate must have completed a university type of residency, there were 10 institutions in the founder's group. Others were soon added, but the total is now only 39 university hospitals. Yet the American College of Surgeons states, "By October 18, 1957, there were 1,520 acceptable programs in general surgery and the surgical specialties in 691 hospitals each approved by the College." This did not occur without turmoil, so it may be profitable to look at what has taken place.

The high priority given board certification by government agencies, courts, insurance companies, hospitals, and schools made it desirable. The economic and professional rewards were great so that the attainment of certification had a profound consequence on professional life. The certifying boards at first preferred and later required residency training as a prerequisite to examination. This led to a rush for residency training which could not possibly be met by the established training centers, for they were too few in number. On the other hand, the resident was reluctant to spend time in a hospital where he did not receive "credit," so "unapproved" hospitals had difficulty in filling their resident staff in spite of a large number who desired training. This led to pressure for "approval" and to the creation of residencies that did not remotely resemble the original system or, as Mulholland[4] puts it, "led to a modern mockery." The term "resident surgeon" lost its connotation.[5] This was not universal, and strenuous efforts were made to resist it by the uni-

Table 3.—*Patient Days for Surgical Services, Strong Memorial–Rochester Municipal Hospitals, 1951-1958*

Surgical Service	1951-1952	1952-1953	1953-1954	1954-1955	1955-1956	1956-1957	1957-1958	Total No.	Total %

versity clinics and their faculty. The Conference Committee on Graduate Training in Surgery was founded in 1950 with representatives of the American Medical Association, the American College of Surgeons, and the American Board of Surgery to improve standards for residency training. The certifying boards tightened their rules and, as weaknesses developed, made more rules. Now the whole subject is hedged in by restrictive requirements,[6] all of which were honestly designed for improvement.

The original intent of residency training was the education of the surgeon. In its rapid expansion this was ignored by many, so corrective regulations were needed. This led to the basic difficulty of regulatory bodies invading the field of graduate surgical education despite the fact that they were not educational institutions. As stated previously,[6] "Residency training is not an exercise in manual dexterity, nor is it a trade school, but rather is graduate surgical education and, as such, belongs under the jurisdiction of the medical schools."

Impact of Medical Insurance

Medical insurance has had a catastrophic effect on residency training in surgery. If this appears to be too strong a statement, let us look at the facts.

The basic principle of the residency system is graded, progressive responsibility under supervision terminating with at least a year when the chief resident is largely responsible for the management and operations of the clinic patients. This is the crux of the method, for without it confidence, judgment, and technical skill are difficult to acquire. The resident in surgery can be carried far, but never finished, if only private patients are available. Yet in most university-owned teaching hospitals and in most private hospitals medical insurance has converted the clinic patients into private patients. The municipal, state, and federal hospitals have not been affected as much. Without clinic patients the basic requirement of graded responsibility for the residents cannot be met. But clinic patients do not pay the whole cost of their care, so a deficit is created. This may be paid by community or tax funds, but in a university-owned hospital it usually comes from endowment. In former years this deficit amounted to as much as $250,000 a year for the Strong Memorial Hospital, and this strained the budget in other areas of the university. Hospital insurance wiped out this deficit but in doing this cut the number of clinic patients who are so necessary for surgical teaching.

The increase in private patients in this teaching hospital has been shown[7] to correlate with the rise of Blue Cross in the community (fig. 4) and to be independent of the national income. In addition to hospital insurance by Blue Cross, there are medical indemnity insurance plans, workmen's compensation, state aid to crippled children, and some types of federal aid which add to the total effect of medical insurance. The decrease in clinic patients at the Strong Memorial Hospital is shown in figure 5, where it is seen that, in 1934, when Blue Cross began in Rochester and when semiprivate patients were admitted to the wards, the clinic patients accounted for 68% of the admissions. This dropped to 8% in 1948 in spite of resistance by the faculty, for this hospital is owned and operated for teaching. Without the 320 beds of the Rochester Municipal Hospital, which is an integral part of our medical center, we could not have maintained our standards of surgical training. Alarmed at this trend, we arranged that unassigned, unreferred patients with hospital insurance who could not pay a fee and did not want their own surgeon should be assigned to the wards as clinic patients. They were cared for by the resident surgeons under supervision. This raised the level of clinic patients to about 20% of the admissions in 1950. But in this same year Blue Shield was started in Rochester. This surgical insurance provided a fee for the operation which injected a new complication and caused some patients to be removed from the group with hospital insurance who were being admitted to the clinic. The rise in Blue Shield surgical insurance is shown in figure 6, where it is seen that in seven years over two-thirds of the Rochester population has obtained this insurance. This and other insurance has reduced the total clinic admissions to 12% in 1958. In addition, there are 300 clinic beds in the municipal hospital.

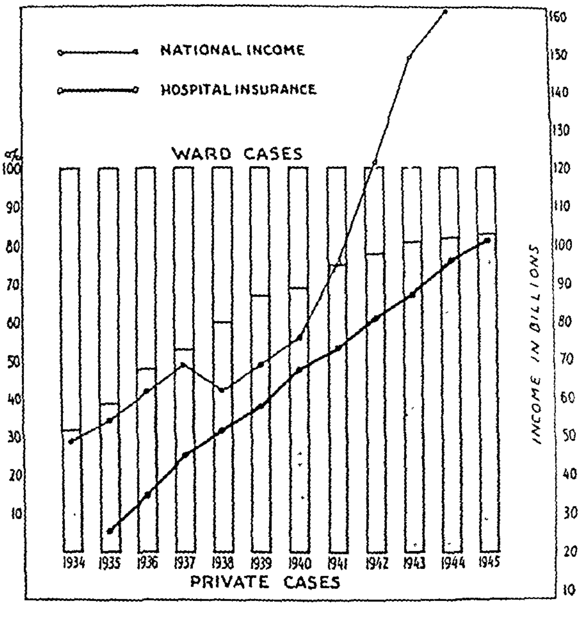

Fig. 4.—Relationship in Rochester, N. Y., area of increase in number of private patients to growth of hospital insurance and not to national income.[7]

What can we do? On the one hand the certifying boards have stipulated residency training as a prerequisite which has enlarged the resident staff, while on the other hand hospital and surgical insurance has so depleted the wards of teaching and private hospitals that they no longer have an adequate number of clinic patients to train residents. It is a good thing we have a municipal hospital and an affiliation with a veterans' hospital. But this is only a reprieve. Medical educators and the surgical profession must face up to the fact that the great benefits of medical insurance, to them and to the public, cannot be permitted to wreck training for proficiency. We cannot afford to have a generation of poorly trained surgeons.

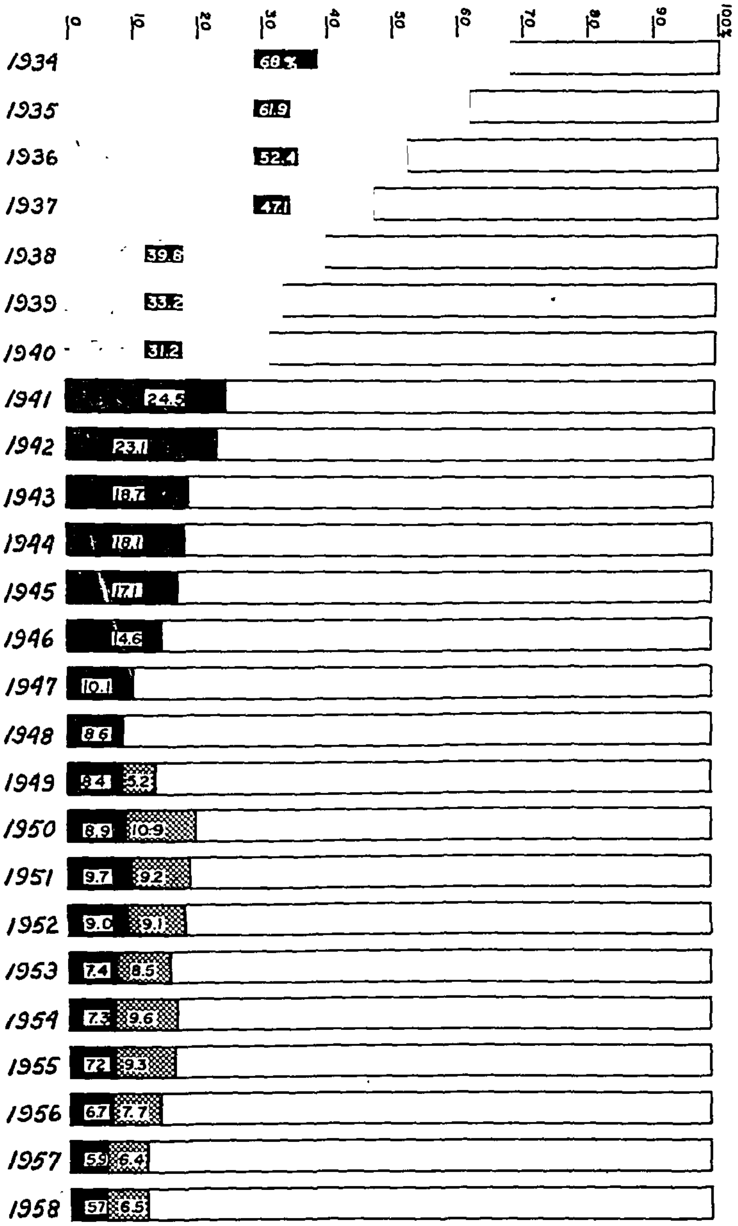

Fig. 5.—Decrease in number of clinic patients, Strong Memorial Hospital, Rochester, N. Y., 1934-1958 (black part of column=ward patients, crosshatching=semiprivate and unreferred patients with hospital insurance, and white=private and semiprivate patients).

Various expedients have been tried in order to combat this critical situation. Some medical centers have instituted group practice: the entire staff, senior and junior, are full-time, salaried, and practicing together as a group. This allows delegation of responsibility for care on the basis of medical need rather than financial standing. When the control of this is vested in the institution, some members of the staff complain that they are exploited. When the control resides in the surgical staff, where it belongs, it has been satisfactory. But to change an already existing arrangement of individual practice by a large full-time and part-time staff to one by a small, full-time, salaried group is complex and difficult—so much so that it is hard to visualize how it could be a universal answer. Another suggestion is to appoint the senior members of the resident staff to a position of junior attending surgeons who are licensed to practice and are approved for the care of insurance cases. This involves an exercise in semantics with the certifying boards, the insurance companies, and the public. The commonest expedient, at present, is to allow the resident to assume more responsibility in the operations on private patients. If this is carried to the point of lack of supervision by the responsible surgeon then it is dishonest, for the resident becomes a "shadow surgeon." Worse, it sets an example for a man, at an impressionable age, to ignore legal and ethical responsibility in order to attain a justifiable goal. Such a haphazard arrangement cannot be the permanent basis for a training program.

The straightforward approach is to have the residents licensed to practice and approved for the care of insurance patients. But when a fee is involved it becomes a bone of contention. This has blocked efforts to use insurance cases for residency training. In my opinion, these fees should be accredited to the surgical staff who have the ultimate responsibility for the care of all of the surgical patients. This staff should act as trustees of any such funds to decide on their disbursements. An unassigned, unreferred patient with surgical insurance who comes to a hospital is assigned to some member of the surgical staff who collects the fee. It follows that these fees are now the property of the members of the surgical staff and should remain so. If these patients were assigned to the resident staff who did the work it would be selfish not to allocate a part or all of the funds to improve the educational and economic conditions of the residents. We felt that a special fund should be created by the surgical staff to be used for the benefit of the residents.

In 1952, this arrangement was started and a request was made to authorize the resident to care for patients with Blue Shield and workmen's compensation. When representatives of the county medical society heard of this they objected, for, they said, it would mean that the hospital was practicing medicine. It did no good to point out that the hospital had nothing to do with it and that control was vested in the surgical staff. The request was disallowed on the basis that it would lead to "socialized medicine."

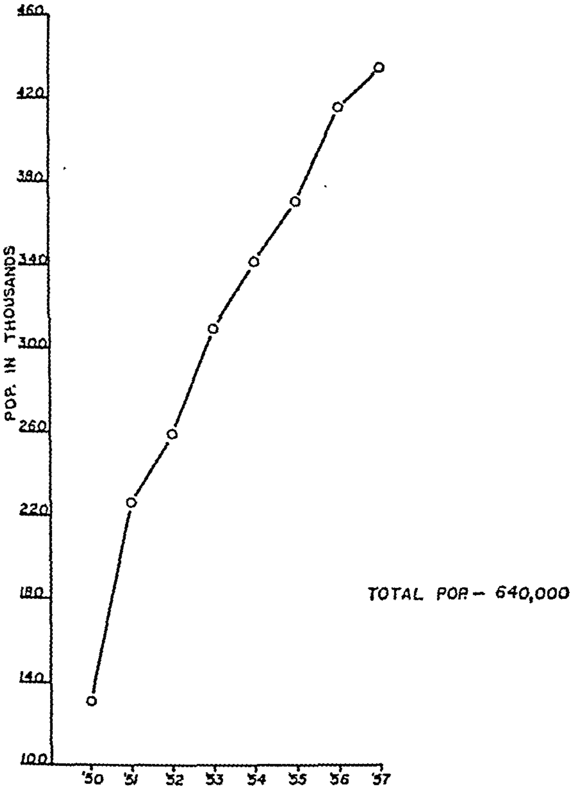

Fig. 6.—Blue Shield surgical membership in Rochester, N. Y., area, 1950-1957.

In New York state the corporate practice of medicine is illegal. This is a wise provision, for no one wants lay control of professional practice. But the medical society of the state of New York has gone beyond this by indicating that not only no hospital or institution but also no resident or intern shall have charge of Blue Shield patients. Now we must sign an affidavit on each Blue Shield form which reads: "I certify that I am not an intern or resident and that this is a true and correct statement for services which were personally rendered by me as attending physician."

This attitude completely ignores the need for training skilled surgeons. In an effort to prevent institutional practice, education has been handicapped. Unless something is done the public will suffer, for they will become the unsuspecting subjects of inadequately trained surgeons. We must exert all of our efforts to prevent this. Some way, somehow, we must find a way to retain the benefits of both medical insurance and the residency system of training. This is the challenge.

IATROGENIC DISEASES.—The term "iatrogenic" is a neologism which has apparently come to stay. It has been attributed to the late Sir Arthur Hurst who originally applied it to disorders induced in the patient by autosuggestion based on the physician's examination, manner or discussion. Its meaning has been extended to include any untoward incident resulting from medical or surgical treatment. . . . In spite of the great advances of medical science each new procedure or new drug seems to carry with it potential dangers. It therefore behooves every medical practitioner constantly to be on the alert for unexpected mishaps. Some may be due to lack of skill, some to lack of knowledge whilst others appear to be unavoidable. It is therefore important to be acquainted with the possible risks of each new or unfamiliar drug or procedure and to have at hand the means to counteract any emergencies which may arise. If risks can be anticipated it may be wise, in view of possible medico-legal repercussions, to warn the patient in advance. On the other hand, it is equally unwise to strike terror into the heart of a patient when risks are minimal.—W. G. Sears, M.D., Iatrogenic Emergencies, *The Practitioner,* April, 1959.

MAINTENANCE OF STANDARDS IN GRADUATE MEDICAL EDUCATION

Edward L. Turner, M.D., Chicago

Shortly before the middle of the 19th century, leaders in medicine evidenced increasing concern over the low standards of medical education and practice in the United States. During meetings of the New York State Medical Society[1] in 1844 and 1845, several resolutions dealing with medical education and licensure were introduced. Lively discussions followed; it was obvious that something should be done, but it was equally apparent that it would be impractical for one state alone to try to raise standards. It was subsequently suggested that this obstacle to improving standards might be obviated at a national medical convention, where the delegates from medical societies, medical colleges, and institutions of the several states might be persuaded to act in cooperation on this important matter. Therefore, the following resolution was introduced:

> WHEREAS, it is believed that a National Convention would be conducive to the elevation of the standard of medical education in the United States; and
>
> WHEREAS, there is no mode of accomplishing so desirable an object without concert of action on the part of the medical colleges, societies and institutions of all the states, therefore, be it
>
> *Resolved*, that the New York State Medical Society earnestly recommends a National Convention of delegates from medical societies and colleges of the whole union to convene in the City of New York, on the first Tuesday in May, in the year 1846, for the purpose of adopting some concerted action on the subject set forth in the preamble.
>
> *Resolved*, that a committee of three be appointed to carry the foregoing resolution into effect.

Although many expressed doubts regarding the possibility of such a venture, some considering it impractical or even "Utopian," the majority of the delegates were impressed with the importance of the objectives and the resolution was adopted. The National Medical Convention met in New York on the appointed day in May, 1846, and reconvened on May 5, 1847, in the Academy of National Sciences in Philadelphia. At that meeting the delegates heard the reports of the committees appointed at the New York meeting, one of which resulted in naming the organization the American Medical Association. It is a matter of more than passing interest to point out that 250 delegates attended this meeting, representing 28 states, 40 medical societies, and 28 medical colleges.

At this meeting resolutions were also adopted recommending certain standards of preliminary education for those who planned to study medicine. These resolutions, however, were adopted only after overcoming considerable opposition, such as is still encountered whenever elevation of standards is discussed. For instance, some members of the convention felt that the recommended standards would prevent from entering the medical profession persons of limited means "whose natural endowments would carry them to the highest rank, notwithstanding their inadequate preliminary preparation." The records indicate that during this argument one of the leading proponents for adoption of the standards stated, "Young men who had not mental energy and perseverance enough to comply with the standard proposed in the resolution, certainly had not enough to enable them to do justice to a profession as extensive, intricate and arduous as ours."

Development of Standards

The philosophy underlying efforts to cooperatively develop sound standards in medical education over a century ago was based on dissatisfaction with existing conditions. Leaders in the profession at that time recognized that the status of medical education was not in keeping with the knowledge and needs of the period. They were aware of the fact that many persons were being graduated into the ranks of the profession without possession of the background education and training essential and available at that period and that this was not in the best interests of the patients. The objectives of those concerned with the concerted effort that gave birth to the American Medical Association were, therefore, to make it possible to develop standards which would improve medical education to what it should have been in the setting of that period.

The concept of standards applicable to the education of the physician reaches far back into antiquity. Such standards are clearly implied in that portion of the Oath of Hippocrates[2] dealing with the physician's responsibility for teaching those seeking to enter the profession. Frederick II,[3] in the law which he promulgated in 1240 A. D. for the regulation of the practice of medicine in the Two Sicilies, under the jurisdiction of the School of Salerno, recognized that the physician must be an educated man. Standards of requirements for admission to the study of medicine were included along with those developed for both medical education and the privilege to practice. In fact, from many standpoints these high qualifications were of such a nature that only the most recent medical legislation has caught up with some of them.

It must be pointed out that the term standard has numerous connotations, which vary with the context. At least two of the possible interpretations are of importance in their application to the area of our concern during this Congress.

Director, Division of Scientific Activities, American Medical Association.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

A standard may be interpreted, according to Webster,[4] as "something established for use as a rule or basis of comparison in measuring or judging capacity, quantity, content, extent, value or quality." When used in this manner, the concept of standard implies a more or less permanently fixed idea, such as an inch, a meter, a pound, a kilogram, or even the exact pattern of the practice of medicine in the "good old days." This utilization of the term conveys the concept of something which, once established, constitutes a permanent, fixed reference point. Such a concept of standard applied to education or training in medicine, or in any other field, becomes a hurdle to progress. It is, however, the interpretation of many of those living in the past and oblivious to or not in sympathy with the problems of today or the challenges that lie ahead.

A standard also, according to Webster, constitutes "something used by general agreement to determine whether or not a thing is as it should be," as a type, a model, or an example established by usage or a level or grade of excellence or attainment which is regarded as a goal or measure of adequacy.

Thus, we are confronted with two different concepts of the philosophy underlying standards: One deals with the establishment of clear-cut reference points to which everything must be adapted or standardized, and the other presents the concept of challenge to maintain a grade of excellence and attainment as a goal or measure of adequacy. This latter concept does not convey the idea of something fixed or unchanging but, rather, implies adaptation to change as a fundamental factor in the maintenance of standards. In other words, there is a vast difference between the concept of standards as applicable to a field, such as medical education and practice, and that of standardization, which in these days may rapidly relegate the concept of a fixed standard to obsolescence.

Hazards in Maintenance of Dynamic Standards

Efforts to develop concepts of dynamic standards in any field of education in today's rapidly changing setting are fraught with certain hazards. This is well illustrated by an incident which took place as long ago as April 4, 1909, when the Council on Medical Education voted to recommend a 4,100-hour program as "a working schedule for the medical curriculum."[5] The Council had consulted with over 100 leading medical educators of the day in the course of developing this suggested guide and specifically indicated that "it was the general opinion of those present that this schedule should not be made a hard and fast requirement with which all colleges should comply, and that strict uniformity of curricula among all colleges was undesirable." Here the Council was clearly indicating its concern that standards not be construed to imply standardization.

However, at their meeting on the next day, the Council reviewed these recommendations and concern was expressed by some that certain state examining boards might adopt the curriculum suggested by the Council as a fixed standard or guide and make it obligatory for medical colleges if their graduates were to be qualified for examination. To counteract any such inflexible interpretation, the Council adopted this resolution:

> WHEREAS, the object of the Council on Medical Education in appointing a Committee on Medical Curriculum was entirely educational and suggestive, and,
>
> WHEREAS, the impression prevails among medical teachers and members of the state boards that the Council is framing a curriculum for the purpose of having it serve as a standard to which medical schools must conform or be condemned by the state authorities as not in good standing, therefore, be it:
>
> *Resolved*, that every publication of a curriculum that hereafter may be made by the Council, its members, or its officers shall state explicitly that the Council does not consider it in the interest of true progress in education that any standard curriculum whatsoever shall be uniformly adopted by all medical colleges.

This historical note on the curriculum illustrates two important points, previously implied, which are associated with the development of standards in the field of graduate medical education. The first is associated with the danger of inflexibility of interpretation and the consequent misuse of the application of standards in any given period or setting. Second, in the rapidly changing world today standards in a field such as education and training must, in addition to being subject to some flexibility of interpretation, also be subject to constant reevaluation and readjustment, if they are to represent the the currently desirable goal, grade of excellence, or measure of adequacy.

Means of Adjustment of Standards

Recent years have witnessed increasing interest on the part of medical faculties, specialty boards, organized medicine, hospital administrators, and licensing bodies in the field of graduate medical education. Except for a few outstanding situations, relatively little interest in this field of education was manifested during the first decade of this century by others than the leading clinical teachers and those young physicians seeking additional experience.

In response to an increasingly obvious need, the Council on Medical Education of the American Medical Association began about 45 years ago the annual listing of hospitals offering satisfactory internship opportunities.[6] Subsequently, in 1919, the Council took leadership in developing certain basic guides or standards which were presented as the "Essentials" or minimum requirements for internship training in hospitals seeking approval for such programs. These basic standards were developed in consultation with leading clinical teachers. They have been *subject to constant review and revision* in efforts to align them appropriately with current knowledge and trends of any given period. Since 1928 the American Medical Association has maintained a field staff to assist the Council in the evaluation of these programs in terms of the "Essentials" and to aid those concerned with this phase of medical education in developing and maintaining adequate programs.

As the trend toward specialization advanced, the American Medical Association, through its Council on Medical Education and Hospitals and in cooperation with representatives of the specialty fields and eventually the specialty boards, undertook the task of developing basic standards or "Essentials" for graduate education and training beyond the internship. These have been prepared as guides to assist those developing such programs as well as to furnish information to persons seeking such opportunities. The Council's field staff visits institutions which have applied for approval of residency training programs and at periodic intervals revisits institutions conducting programs previously approved. Reports of the findings during such visits are submitted by the field staff to the Council and specialty boards and constitute part of the evaluation process currently utilized in the approval and annual listing of programs in the field of graduate medical education.

In order to obviate unnecessary duplication of effort as well as dual concepts and interpretation of standards by the Council, which approves programs, and the specialty boards, which evaluate and certify individual physicians as meeting specialty qualifications, the Residency Review and Conference Committee[7] procedure was developed. These committees, representing both the Council and the specialty boards, have cooperatively reviewed and revised the "Essentials" in keeping with the changing scene. Furthermore, this cooperative function extends to the responsibility for approval of residency education and training programs, subsequently listed by the Council in the annual internship and residency issue of THE JOURNAL. One of the most important objectives of this liaison has been to foster opportunities in residency education and training for total programs in any given institution or through appropriate affiliations so that the resident may be assured of reasonable continuity and upgrading rather than undergo fragmented, isolated, and inadequate segments of experience.

The 1940 Report of the Commission on Graduate Medical Education[8] clearly indicated the objectives and basic principles underlying the internship, residency experience, and postgraduate education. The need for constant study and reappraisal, intelligent experimentation, and flexibility of thought and action is emphasized throughout this report, most of which, with minor modifications, is pertinent to the current setting.

Perspective in Specialization

Graduate medical education has not developed on the basis of careful study or projection of needs in specialty areas. To date, graduate medical education and training has developed in response to the interest of leaders in the various specialty areas. Clinicians as well as hospital administrators recognize the valuable service functions which accompany the educational aspects of intern and resident programs. Through the activities of the Council on Medical Education and Hospitals, the American College of Surgeons, the American College of Physicians, the specialty boards, the Association of American Medical Colleges, and other interested organizations, it has been possible to maintain some semblance of order in graduate medical education out of what might otherwise have resulted in chaos equivalent to or worse than that existing in medical schools at the turn of the century.

Today there are no absolutely clear-cut lines of division between the clinical clerkship of the final year in medical school, the internship, the residency, and even some aspects of postgraduate medical education. In many instances the same facilities and patients are being utilized and the same faculty personnel may be involved in all of these areas of medical education. Advances in knowledge have been of such magnitude that the medical school experience alone no longer qualifies a physician to enter practice but, rather, furnishes the initial plateau on which he erects the additional education and training essential to qualification for general practice or a specialty.

It is natural, in view of this rapidly changing panorama, that there has been aroused interest and concern on all sides regarding the various phases of medical education, particularly with its graduate aspect today. In the 40 years since the establishment of the standards suitable for qualification for the first of the approved American specialty boards, 18 other basic specialty boards have been approved. In addition, there are 6 areas of certification in subspecialties and 28 areas of special certification for a total of 53 different sets of standards and qualifications.[9] These constitute only those specialties, subspecialties, or areas of special certification which have met approval of the American Medical Association through the recommendations of the liaison mechanism established between the Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties.

The rapidly changing advances in therapy since the establishment of the 19 approved boards in the medical specialties have necessitated major alterations of requirements and standards for some of them in order to justify their continuance as identifiable entities. Natural history[10] furnishes many examples of the situation in which, as time goes on, the very qualities which initially insure success and constitute "fitness" may eventually prove a handicap to specialization. Where an area of interest is too narrowly specialized to a given set of conditions, the specialty has the potentiality of succumbing if the conditions justifying its original development disappear or become markedly altered. The warnings of natural history are worthy of serious thought today as the trends for narrow specialization continue, for, in the long run, excessive specialization or overrigidity in the application of standards may become distinctly disadvantageous and result not in survival but in extinction or stagnation.

In the course of this review, I have endeavored to portray first the early background efforts of the medical profession in the United States to develop standards for professional education. This early concern stemmed from the desire of medical leaders to make it necessary for persons entering the field of medicine to do so through having opportunities for education and training in keeping with the knowledge and needs of any given period and in the best interests of their future patients. It was apparent from the beginning of this effort that the development and maintenance of sound standards necessitates cooperative effort and cannot be achieved by a single state or organization. The philosophy underlying these early efforts to develop standards in medical education was based on dissatisfaction with existing situations and a desire to elevate the education of the profession to what it should be.

WORKSHOP CONFERENCE ON SPECIALISM IN MEDICINE

I. RESIDENCY PROGRAM

Wright Adams, M.D., Chicago
and
George A. Wolf Jr., M.D., Burlington, Vt.

The Workshop Conference group on Specialism in Medicine concerned with the residency program started with a kind of explosive force. The intense interest in the subject stemmed from the fact that the number of residency positions available rose from 7,666 in 1945 to 27,835 in 1956[1] and that four new American specialty boards were created in the same period of time.

To summarize the "talk" which occurred would consume much space, and to identify the emotions which darted about would require uncommon qualities in a scribe. In the first place, the panel was composed of experts; all members, as in local Parent-Teacher Associations, had been through the mill and knew all about it. The true experts (the young residents) spoke with a voice of good sense but, unfortunately, had not experienced the "good old days" and were thus automatically disqualified. It was agreed, however, that residents are underpaid, and note was made of the fact that some had to work out of hours for pay to support wife and family. Many residents, although presumably being educated, do not have time to read during their course of instruction. Finally, in some instances, the resident seemed to be more of a hospital employee than a true arm of the chief of service.

The ills of the residency program were blamed indiscriminately on the specialty boards, the American Medical Association, the Council on Medical

---

Professor and Chairman, Department of Medicine, University of Chicago School of Medicine (Dr. Adams), and Dean, University of Vermont College of Medicine (Dr. Wolf).

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

Education and Hospitals, the Advisory Board for Medical Specialties, the Joint Accreditation Commission, and the university teachers.

It was illuminating to realize that the American Medical Association, through the Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties, merely determines certain *minimum* standards for the establishment and recognition of specific specialty boards. The boards determine their own programs of training and give examinations. The Council on Medical Education and Hospitals inspects residencies to see if the rules laid down by the specialty boards are followed. The Joint Accreditation Commission concerns itself with the hospital as a service and not as a training institution. The university hospitals are inspected by both groups and do not set minimum standards, although we hope they might point to maximum ones.

We then pursued the objectives of a residency training program. In brief, everybody was against sin, and for a while it appeared as though research as part of a residency program was a sin. Research was variously defined all the way from that conducted by the bearded savant who frightened patients in his musty basement laboratory to that of the tippling dilettante whose scientific curiosity begins and ends with asking the question, "Where am I?"

Cooler heads prevailed, and it was finally conceded that few of us (residents included) are true academic career investigators but that many of us approach a clinical problem with a base of scientific information, accumulate data by careful observation, synthesize the data into a working diagnosis, and plan and execute controlled therapy.

We neglected to explore the educational process from the standpoint of the truism that teaching and research go hand in hand and that the teacher who is not constantly testing his knowledge, questioning its validity, and adding to his fund of proved information is not a teacher but, as one bright student said, "a person who is transmitting static ignorance from one generation to another."

There was no doubt that we all wanted to train a good physician, but at that point, as usual, we were unable to define a good physician. "Honest" and "qualified practice in the area of his interest and training" were mentioned. This was good until somebody said "private practice," and the fight was on. Almost in tears, one of our members predicted the demise of solo private practice, and the academicians immediately jumped to the conclusion that training for private practice was directed against academic medicine.

Eventually, it became clear that we all should encourage young people to go into academic medicine because of the shortage of teachers. It was agreed that undergraduate medical schools should not be loaded with too much specialty training and that the education during the undergraduate years should be basic. Nobody defined basic, however. Training in university teaching hospitals should provide opportunities for those interested in academic medicine as well as the practice of medicine in whatever form. Nonuniversity teaching hospitals have a job to do in preparing physicians for the practice of medicine but need not discourage interested residents from entering academic medicine.

The quality of the teacher came up for the usual discussion. Here, the all-or-none law prevailed—investigators were poor teachers, practitioners were poor teachers, and so forth. In stereophonic, however, it sounded as though the good teacher was a person with time to teach, with interest in teaching, and with adequate curiosity and energy to educate himself continually. He had the ability of delegating to residents the care of patients under supervision according to the stage of development of the individual resident. It was emphasized that medical student teaching by residents assists in the learning process of the latter. It was abundantly clear that the best residency program, according to the book,' and the best teaching hospital are no better than the teacher involved. A good teacher could guide a resident into doing some original investigative work, and this experience in itself was felt to be of some value to the training of the resident as a practitioner.

Residency training programs which are rigid and prevent the development of originality in a resident were scored. Rigidity and narrow experience might lead to the training of supertechnicians in certain fields, but general training as a physician was felt to be necessary. The point was made that a specialist in a restricted field must either have some general training enabling him to give full care to patients or else limit himself to consulting practice. Here it was not clear whether the basic training needed prior to the residency program was to improve the understanding of people and human pathophysiology or to prepare the specialist to take care of most of the diseases he would find in certain specific practice circumstances.

The spirited discussion raised several questions which need answers: What is basic to the education of all physicians prior to entering upon specialty training? Should this vary in the case of certain limited specialties? Can specialty boards establish minimum standards without imposing rigidity of program and preventing development of originality in the resident? Are there too many specialty and subspecialty boards? Can university medical education and hospital training for general or specialty practice be defined more clearly?

Miss Theresa E. Falaguerra, assistant project director, Bureau of Applied Research, Columbia University, assisted in preparation of this report.

WORKSHOP CONFERENCE ON SPECIALISM IN MEDICINE

2. THE SPECIALTY BOARD

John M. Mitchell, M.D., Philadelphia
and
Sam W. Banks, M.D., Chicago

The Workshop Conference on Specialism in Medicine from the standpoint of the specialty board was opened at 2:15 p. m. with a large attendance. The nature of the facilities precluded a satisfactory round-robin talk by the members of the workshop panel, and the chairman invited all guests to participate. There was a lively discussion from the floor throughout the proceedings.

As an introduction, the purposes and functions of a specialty board as described in the "Essentials" were elaborated on as follows: (1) to assist in improving the quality of graduate education in that field; (2) to establish minimum educational and training standards in the specialty in conformity with the general provisions of these "Essentials"; (3) to determine whether candidates have received adequate preparation as defined by the board; (4) to provide comprehensive examinations to determine the ability and fitness of such candidates; and (5) to certify the competence of those physicians who have satisfied the requirements of the board as a protection to the public and the profession.

After this, the history of the development of specialty boards was outlined. It was brought out that, in the early days of specialization in the United States, there was no mechanism by which a person might be identified as a specialist. Many men entered the field of specialization from general practice after having gradually developed their work in a single area. Other physicians entered specialty practice through residency training, but the residency training programs in those days were determined entirely by the chief of service and the facilities at his disposal. The duration of training was, in its turn, determined by the chief or by the whims of physicians undertaking training. Other physicians entered specialty practice through preceptorships, while still others, after a vacation period of indefinite length abroad in which they might or might not have really participated in training programs in one or another of the European capitals, returned and declared themselves as specialists. It was to meet this highly unsatisfactory situation that the first specialty boards came into being.

The belief was expressed that medical schools at this time were in no position in terms either of personnel or of finances to undertake the regulation of specialty training and the boards filled this gap. The belief that medical schools were not in a position to do this was not held by everyone, the opposing opinion essentially being that there was a lack of appreciation on the part of schools of what was happening.

The Training Program

The rapid growth of specialization and of residency training programs was indicated by the fact that at their inception in the first decade of the present century 2,000 residency appointments were in existence throughout the United States while today there are 25,000 physicians in residency training.

Some expressed the view that the boards should not enter in any way into the conduct of residency training programs and that they should not have requirements for a specified period of training prior to certification. It was postulated that the board's only function was to certify to the competence of the person to practice the specialty. The mechanism by which this competence was attained should not essentially be the concern of the board; it should depend entirely on an evaluation process to determine who should receive its certificate.

It was brought out, however, that no one could say with authority that any particular plan of training was necessarily the best or only acceptable plan and that every person required the same sort of training. The procedure thus outlined follows fairly closely the English system, in which full dependence is placed on the examination.

In rebuttal, it was noted that some 75% of candidates in Great Britain flunked the first examination because their training had been unsuitable, whereas in the United Sates, where training programs are prescribed, the failure rate is not nearly so great. Further, it was noted that although specialty boards set minimum standards many allow for flexibility within the stated program through one or another device. Further, in support of the system in the United States, it was brought out that many hospitals with relatively weak training programs had sought assistance of the boards and, with this aid,

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

had been able to improve their training, resulting in raising the level of residency training and of specialty practice.

The Examination to Determine Competence

The question was raised as to whether we can depend on an examination as the sole means of determining the competence for specialty practice. It was the general consensus that this could not be depended on and that consideration must be given to other factors, namely, the site of training, the duration of training, and the evaluation of the trainee by chief of service.

It was emphatically brought out that the board can only certify that the candidate has fulfilled the training requirements, that he has been recommended by his peers, and that he has passed the examination of the board. There seemed to be general agreement that this was as far as the board could go, and it was reiterated emphatically that the boards did not consider themselves to be licensing bodies but that the certificate was more in the nature of a degree—that is, it indicated a certain background of experience and the ability of the person to pass the examination at a given time.

Uses of the Certificate

It has not been the intent of the boards that the certificate be used to limit staff appointments to those who hold certificates, to give grounds for preferential treatment in terms of compensation for diplomates of boards on certain government services and hospitals, or to indicate that those who do not hold certificates are not competent and that they should be necessarily limited in their freedom to practice a specialty. However, it was brought out that other agencies than the boards themselves did use the certificate as a criterion for their own purposes and that this should be admitted. Several persons saw no objection to this. In any event, all agreed that there was nothing the boards could do about it.

What does specialty board certification mean to the profession and the public? This question was raised, but no one seemed to feel qualified to speak for the meaning of certification to the public. It was felt that its meaning to the profession had been covered in other discussions and needed no further clarification.

Residency Training in Approved Centers

No clear-cut statement with regard to a satisfactory substitute for board regulation of residency training programs was brought forward. It was suggested that a searching examination might be used for this purpose. The belief was stated by one member that this was possible in certain specialties, such as pathology. Nobody, however, was able to bring forth a satisfactory alternative plan, and, while the desirability of flexibility was expressed by many, in practical application it was felt that some evaluation and regulation of training programs was necessary, at this stage in our development, with many hospitals lying entirely outside regularly constituted teaching centers. Many of these hospitals conduct highly satisfactory training programs, but a high percentage need guidance and assistance and many turn to the boards for this help.

Questions were asked on the number of specialists to be trained and the anticipated needs for the future. No answer was forthcoming, but it was indicated that a balance between supply and demand was maintained by the mechanism whereby unoccupied residencies were dropped and, when new programs were created and not occupied, that they also were inactivated.

NEW OCCUPATIONAL DISEASES.—Every year some 200 disease entities are added to the total number of approximately 3,000 occupational diseases. This increment is more than the aggregate for all other medical specialties combined. It may be doubted that any professional distinction resides in this continually mounting lot of added affections, but the fact reveals the tempo of industrial medicine and the requirement for swift adjustment in meeting increased professional burdens. The majority of the additions represents precisely new entities springing from the appearance of a new chemical compound every 24 minutes throughout the year. Many of these chemicals never become important to production. Of those that do, the majority prove innocuous as to toxic properties. There remain those highly significant ones that possess harmful properties for sufficiently exposed workmen.

A second source of the yearly increase in occupational diseases is the fact that many pathological states, long regarded only as diseases common to ordinary life, under special circumstances become true occupational diseases. . . . An example is psittacosis. In the early days this disease was regarded foremost as a threat to the owners of pet psittacine birds. Soon it became apparent that dealers readily might be involved. Still no label of occupational disease was applied. Only in recent years has the proper category appeared after the high incidence of psittacosis in the fowl packing industry brought about the full acceptance of this disease as inescapably occupational under some circumstances.—Carey P. McCord, M.D., The Zooanthroponoses, *Industrial Medicine & Surgery*, April, 1959.

WORKSHOP CONFERENCE ON SPECIALISM IN MEDICINE

3. THE RESIDENT AND FELLOW

A. McGehee Harvey, M.D., Baltimore
and
George G. Reader, M.D., New York

The workshop was opened with an outline of the magnitude of the problem posed by the training of residents and fellows. The figures given by Dr. Ernest L. Stebbins were cited: 31,000 physicians studying in 5,000 programs in 1,200 different institutions. This is a far larger area of educational endeavor in medicine than the medical schools themselves provide. With the growth in population and research training predicted by the Bayne-Jones report, it may be expected that by 1970 a billion dollars a year will go into medical education and research. Since less than a third of that amount is now being spent, the rate of growth in the next decade will be logarithmic. It is going to take a great deal of intelligent thought to plan the new training programs and to deal with the competition that will inevitably occur among them.

Various members of the panel were then called on to discuss the problem from their respective points of view. Dr. Robert Glaser spoke as a medical school dean, drawing attention to the dilemma posed by the educational needs and service responsibilities of residents. He emphasized the need to keep residency and fellowship programs education-centered and pointed out that it is far too easy in residency programs for the house officer to become involved in service. If he does, he may develop his technical skills but there is the danger that he will not learn to continue his education in the broadest sense. All of us in medical education are concerned with three functions: education, research, and service. It takes an active effort to see that an appropriate balance between these is maintained for the resident or fellow. In this important phase of his education, service and even research activities must be controlled.

Hospital Problems

Dr. Russell Nelson, a university hospital administrator, referred to Dr. Herman E. Pearse's report on surgical training at Strong Memorial Hospital, Rochester, N. Y., for evidence that the service component of residency training is diminishing in university hospitals. He voiced some concern that the service load continues to be a serious problem in nonuniversity hospitals which have the majority of residency programs. In some of the smaller hospitals, it may actually be easier to build up residency programs to meet service needs than it is to attract interns.

Another problem for the hospital is meeting the resident's economic needs. In most instances his stipend comes out of the hospital's operating income and his economic requirements, therefore, compete with other powerful factors—inflation generally and the increasing complexity of the modern hospital —which are steadily forcing hospital costs upward. But young men and women in residencies should be looked on as graduate students, and their economic needs should be met from that point of view rather than from the point of view of their contributions to hospital service.

Dr. Henry Uhl spoke as director of medical education in a hospital not affiliated with a university. He raised a number of questions germane to this situation. One is the problem of organizing a group of practicing physicians into an effective teaching faculty. He pointed to the long-standing precedent of the full-time pathologist in the hospital serving as the mainstay of any teaching program. Full-time radiologists, anesthesiologists, and clinical department heads may be expected in the future also to form a nucleus for the teaching faculty required in a residency program.

Another problem in the nonuniversity hospital may be the characteristics of the residents themselves. Often these men have less academic ability than their classmates who have obtained appointments in university hospitals. They may therefore require greater efforts to motivate them to learn because their inclination is to occupy themselves merely with technical busy-work. Foreign graduates, too, are absorbed mainly by the nonuniversity hospitals. Their academic preparation in medicine is often less good than that of American graduates, and they may be oriented more to vocational than to educational goals.

The number of candidates who desire residencies may always be expected to exceed greatly the capacity of university hospitals to accommodate them. It is important, therefore, that nonuniversity hospitals achieve an educational atmosphere and continue to raise their standards.

Needs of Medical Trainees

Dr. John S. DeTar, of the American Academy of General Practice, then raised a question regarding the needs of medical trainees in the light of their ultimate role as practitioners. He pointed out that between 40 and 50% of the men graduating from American medical schools between 1940 and 1954 are now in general practice and that this percentage is rising rather than declining. Of those entering general practice since 1940, only 62%

Professor of Medicine and Director of the Department of Medicine, Johns Hopkins University School of Medicine (Dr. Harvey), and Professor of Medicine, Cornell University Medical College (Dr. Reader).

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

have had any residency training at all.[1] Most medical educators agree that a one-year rotating internship is inadequate preparation for practice. Two years is a minimum, and this experience should be especially designed for the man who will be a family practitioner. But, of the 25,000 filled residencies in the United States today, only 468 are in general practice and most of these are inadequate.

The American Medical Association's Committee on General Practice has been working on this problem for the past two years. This committee includes representatives from the Association of American Medical Colleges, the specialty boards, the A. M. A. Council on Medical Education and Hospitals, and the American Academy of General Practice.

Dr. DeTar stated that their present plan is to recommend a two-year program that would replace the internship and one year of residency training. It would consist of 18 months of adult and pediatric medicine and would include dermatology, office otolaryngology, and traumatic and minor surgery. The final six months would be spent in surgery, obstetrics, or a subspecialty of medicine, depending on the type of practice the physician anticipates. The Committee has defined a general practitioner as a doctor of medicine who assumes total continuing responsibility for the health of the individual and his family, and it is believed that the program outlined will serve as a proper basis of preparation for this role. It is expected that further training would be obtained, possibly with specialist preceptors on the hospital staff in the community where the young physician enters practice. Dr. DeTar commented that the Committee hoped the state boards of licensure would acknowledge the value of the program outlined by requiring it in place of the present one-year rotating internship.

Dr. Patricia Kendall, a sociologist on the staff of Columbia University's Bureau of Applied Social Research, then reported some findings from ongoing studies of the attitudes that medical students have toward their professional role.[2] Data are available from students of three schools over a number of years. These students are now being followed through internship and residency training.

The quality of teaching was by far the most important consideration that led them to choose a particular hospital for their internship. Salary ranked very low in their stated considerations, and it seems to be a factor only for persons who, because of family obligations, are under great financial pressure.

The degree of responsibility they expect to have is highly important to them, as are the medical reputation of the hospital and adequacy of patient material. They are wary of being exploited and of being required to do any considerable amount of scut work.

It is becoming evident from their responses that they look on their internships and residencies as progressive educational experiences. What may contribute to learning at one stage, therefore, may later be considered repetitious and trivial. In view of this, it may not be realistic to speak of service and education as a dichotomous dilemma. It may be more appropriate to determine the cut-off point at which certain activities cease to be educational for the resident.

Other Problems

After this, discussion among members of the panel became general. In this discussion and in questions raised from the floor, a number of topics were reviewed. Both residents on the panel, Dr. Albert Fish and Dr. Nahman Greenberg, emphasized the importance of the economic situation of the resident. They pointed out that, although salary was not usually the major inducement for choosing a particular residency, lack of adequate funds often requires the resident to make compromises in his career plans. These compromises frequently limit his potential development.

Others suggested the possibility that the financial advantages of fellowship stipends sometimes caused young physicians to accept fellowships for research training prematurely. By interruption of their residency training, their proper clinical development as physicians may have been handicapped or retarded.

The question of how to compensate for the decline in ward patients was also considered. Whether private patients can be used in residency training is a moot problem. Many felt that the difficulties are more likely to arise with the patient's physician than with the patient himself. If the private physician is sympathetic to the resident's needs, his patient is usually agreeable to being transferred temporarily to the care of the resident. The private physician then acts as preceptor and consultant. This, of course, is more difficult in surgery than elsewhere.

Finally, it was felt that the training of practicing physicians as teachers merits special attention. Hospitals must be so organized as to provide a framework within which the practicing physician can function as a teacher. For these purposes, it is essential to have supervisory relationships, such as those offered by a full-time chief, that serve to instruct the practitioner in his educational role.

525 E. 68th St. (21) (Dr. Reader).

WORKSHOP CONFERENCE ON SPECIALISM IN MEDICINE

4. THE HOSPITAL

Joseph C. Hinsey, Ph.D., New York
and
John F. Conlin, M.D., Boston

"What are the objectives of the hospital administration and the medical staff in establishing or maintaining graduate clinical training programs?"

It was felt that, in essence, graduate clinical training programs were an upward extension of medical education from the medical schools into the hospitals. About one-third of all internships and less than half the total number of residencies offered are located in hospitals making available outstanding educational experiences. Despite continued and concentrated effort, many hospital administrators, trustees, and hospital staff members have continued to place emphasis on the "service" aspects of house staff training.

It is admittedly difficult to render a precise definition of service. However, it was strongly felt that overemphasis of "service to institutions" or "service to staff" with considerably less emphasis on the basic requirement of furnishing an educational experience to the house staff members is undesirable. It was brought out that in many instances a busy service experience can be accompanied by a drive to read and to study and benefit by teaching and consultation opportunities, thus keeping abreast of the rapidly paced service march. Hospital administrators and hospital staffs usually aim at common ends but differ occasionally concerning the methods of obtaining them.

There was considerable discussion of unsatisfactory situations arising from overlapping areas of specialty jurisdictions. It is impossible, administratively, to follow rigid policies of area segregation of various subspecialty patients in general hospitals. There was strong support for administrative grouping of the surgical specialties, including obstetrics and gynecology, and of the medical specialties, including pediatrics.

There was, likewise, strong feeling that many present administrative problems of the hospitals arise from the rather haphazard growth and development of the many specialty and subspecialty boards. A parallel was drawn between widespread efforts to integrate undergraduate medical curriculums and the need to reevaluate and regroup supervision of services and training in the various specialties. The evils of overdepartmentalization, splintering, and fragmentation were repeatedly stressed. The chairman pointed out that two aspects of immortality were represented by the "bureau" in Washington and the "department" in a medical school or hospital.

There was complete agreement that the primary objective in establishing and maintaining graduate clinical training programs is the best service to the public and the best possible care of the patient. Size of the hospital and extent of its teaching program should result in no departure from this basic statement of objective. It was also pointed out that the different problems of teaching hospitals regarding the teaching of undergraduate medical students, interns, and residents, in any combination of these, will have an effect on graduate clinical training programs.

The objectives of graduate clinical training programs will be affected in varying degree by trends in medical care programs, various types of insurance programs, availability of private patients for teaching, and other factors. It was agreed that good teaching programs should not depend entirely on the availability of ward or service patients.

The hospital administration and the medical staff have a major objective in setting the highest possible level of performance of their teaching function, and from this should follow high-level patient care. There was general agreement that research and teaching are inseparable and that it almost invariably follows that where these are of a high level patient care of good quality should result.

One of the hospital's primary purposes is the attracting and holding of an able staff. There seems little question that the establishment and maintenance of a high type of graduate clinical training program is a means of attaining this end.

Compatibility of Objectives and Responsibilities

Question two was as follows: "Are these objectives always compatible with the medical service responsibilities of the hospital and the educational goals of the residents? If there are conflicts, what are their sources?"

This problem was posed in general terms as one of the areas of conflict between service responsibilities of hospitals and the responsibilities for furnishing proper training programs. Considerable discussion hinged around outpatient department services. It was admitted that these services could

---

Director, New York Hospital–Cornell Medical Center (Dr. Hinsey), and Medical Director, Boston City Hospital (Dr. Conlin).

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 8, 1959.

constitute a substantial drain on the time of house staffs. It was further admitted that an outpatient department, doing a proper service job, undoubtedly lessened admissions to the hospital by stepping up diagnostic, treatment, and rehabilitational procedures at the outpatient level. A corollary to this, however, was the increase in hospital admissions due to faster case finding at diagnostic clinic levels.

Attention was given to the aspect of increased reliance on house staff members by the visiting staff in the care of private patients. This function has, of course, elements of both service and education.

After considerable discussion there appeared to be agreement that, despite the advantages of performing and even repeating many low-level technical procedures as part of the learning process, caution must be exercised to avoid wasting of valuable time through undue prolongation of the apprentice period in senseless repetition of unnecessary tasks. The experience of the military forces in the increased use of technical assistants, as for operating room technicians, was cited as an example of a trend leading toward more efficient utilization of professional personnel services.

Where unmet service needs exist, there is a tendency to seek out and use any services available. Many institutions, in the absence of high-quality graduates, have had recourse to the services of low-qualifying foreign graduates, resulting in a lowering of the level of available patient care.

With the increasing complexity of hospital services there have been increasing demands on the services of radiologists and pathologists. This has frequently been interpreted as a local need for increasing the number of residents in these fields, but, in many instances, the local need was for another pathologist or another radiologist rather than for another specialty resident. Areas of conflict have arisen from the tendency to build empires within specialties. There has been a marked increase in the tendency to develop highly specialized services within broad specialty areas.

Residents trained in many highly specialized fields have difficulty meeting the requirements of the broader general specialty needs in the communities to which they go. Various hospital departments, including a wide diversity of highly specialized services, present problems of duplication, overlapping, and costly budgeting.

It was generally felt that it was not necessary to good teaching in good graduate clinical training programs that a department should be completely self-contained with its own radiology, biochemistry, and other specialty groups.

Discussion included the variation in the needs of community hospitals and large teaching hospitals. It was agreed that what happens in the teaching hospitals definitely has an impact on the community hospital, since the latter is a consumer of the professional practitioner services produced by the former. It was strongly stressed that the overspecialized worker, such as a radiologist whose major field of interest is in radioisotopes, may not meet the requirements of a community in urgent need of a well and broadly trained radiologist.

In general, there was agreement that the service responsibility of a hospital can be satisfactorily met outside the training program and without undue interference with the training program.

Provision for Needs of the Residency Program

Question three was "What are the responsibilities of the hospital administration, the medical staff, and the patient population in providing for the needs of residency programs, in terms of (1) teaching personnel and program, (2) research space and equipment, (3) library, and (4) clinical material?" In regard to the first portion of the question, it appears that, in many instances, approving authorities for residency programs are guided by the attitudes of persons in charge of specific programs. These persons are frequently of excellent ability and may be inspired and devoted teachers. It is possible for a teaching program to succeed because of the inspiration and leadership of one person, but it should be pointed out that more than a one-man preceptorship type of training is required; for a program to succeed, interest should extend considerably beyond a single teacher. Satisfactory individual departments and individual performance levels do not necessarily combine to an effective program. There must be a coordinating factor at work.

There was general agreement that teaching programs needed planning and continuing, preferably full-time, supervision. There is a dual responsibility of the hospital administration and of the medical staff to see that standards are set and maintained.

Comments on the second portion of the question, namely, research space and equipment, pointed out that area, cost, and amount of equipment would depend, to a great extent, on the size of the institution and the size of the program conducted. It was stressed that the spirit of research can be had wherever teaching is carried on and that this spirit can grow and develop within the means available to the hospital. It was noted that many institutions are being led into expenditures for research programs where competent persons to conduct the program are not available. There is danger in the concept of "research for the sake of research." There must be available sound planning, the exercise of sound discipline, and the specialized equipment to meet the needs of an available staff and its interests within the limits of the ability of a hospital to supply it.

There was agreement that it is valuable for a resident to be exposed to a research program. He should be encouraged to conduct a modest program of his own, under proper direction. Without this experience, he will lack a proper appreciation in evaluating the results and the reports of others. There is not always time for an extensive research program for residents. It was pointed out that undergraduate medical students, through various fellowships, summertime work, and similar programs, have markedly increased opportunities in recent years for exposure to research programs. It was felt that it was certainly not necessary for all hospitals to offer extensive research opportunities.

In regard to portion three, the library, it was agreed that research begins in the library and that adequate library services should be furnished by the hospital administration for at least the routine needs of residents in training.

Relative to portion four, provision of clinical material adequate in numbers and kind, available statistics show a trend on the part of candidates for graduate training of migration toward larger hospitals and away from smaller hospitals. It was felt that, as the number of graduates increases, some existing vacancies will be filled in order to meet their needs. Progress is being made toward the objective of making available for residency training all patients—private, semiprivate, and public. There are continuing difficulties in various places in making private patients available for teaching. It is felt that the greatest progress has been made in the use of private patients for teaching by groups. There is danger in the selection of the term "use" of the private patient. Actually, the private patient benefits by participation in a teaching program.

Compatibility of Service Demands and Educational Opportunities

The discussion then moved to question number four: "Are service demands and educational opportunities for the resident staff generally compatible?" It was generally agreed that these demands and opportunities are compatible. There are, however, notable exceptions and wide variations in various parts of the United States. The tendency to lengthen periods of residency training was deplored. The remarks made previously (concerning prolonged and senseless repetition of apprentice-type tasks) were felt to have pertinence in the discussion of this topic.

Remuneration for Residents

Question five asked, "What is an equitable financial remuneration for residents? How can it be determined, and what should be its source?"

It was felt by some that pay should be made for services rendered. It was pointed out that in the past decade more residents have married and that the presence of two and three children in their households is not unusual. Lengthy training periods present serious economic problems. It was felt that responsibility for payment for residents' services could be assigned (1) to the hospital, since residents care for patients; (2) to the university, since in teaching centers residents engage in teaching students; and (3) to the patient and especially to third-party sources of payment. It is perhaps forgotten that in one way or another the cost is ultimately passed on to the patient.

The perennial problem of whether members of the healthy community or those of the sick community should underwrite the cost of residency training was discussed, but time did not permit adequate consideration. It is regrettable that prolonged borrowing to finance a lengthy educational experience in some instances leads to concentrated effort to obtain a high level of earning as rapidly as possible in order to "get it back fast."

There is no doubt that many who wish to continue residency training are unable to do so because of financial handicaps and are unable to borrow. This has always been true to some extent. In balance, it must be remembered when considering resident stipends that much is received in return for the opportunity for the resident's educational experience and that this is not immediately measurable in dollar value.

The question was raised whether compensation of residents at a high level would help or hurt. There seems to be little experience to justify opinion in this area. There was some feeling that too-high levels of payment might lead to undue prolongation of periods of resident training.

The Hospital Director of Medical Education

The discussion then moved to question six: "What is the proper role of a hospital director of medical education? What should be his relationship to the hospital administration, medical staff, house staff, and patient population?"

The position of hospital director of medical education has evolved rapidly in the past few years. This responsibile position has been of great advantage in instances in which there has not been a continuing responsibility for a resident training program. In many hospitals service chiefs rotate at frequent intervals—in some instances more than once within the same year. Such lack of continuous direction and control obviously works against satisfactory educational programs. Many of these situations have been satisfactorily resolved by obtaining services of competent, well-trained young men with special interests and abilities.

Special problems concerning this relatively new area of responsibility have been discussed at various times and, as recently as within the past month, at a meeting of hospital directors of medical education conducted under the sponsorship of the American Hospital Association. Unfortunately, lack of time prohibited additional discussion of this topic at this workshop.

Related Comments

Lest the monotone of this report imply that the discussion was gentle and even desultory, your reporter begs leave to toss in these few random direct quotes:

"The house staff renders professional services. Why shouldn't the visiting staff contribute toward payment of their salaries?"

"Certainly we residents cannot ask for all we would be worth in practice."

"Many hospitals feel that the better the residency the lower should be the pay. Many prospective residents simply cannot afford to go on with this view."

"Much that is now regarded as education adds only to the length and not the quality of educational programs."

"Groups are fine but it will not be a good thing if we close-group all of our teaching centers."

"In my day, as resident, we felt we were lucky to get what we got. Our babies were our own responsibility and not that of the community. Residents should have enough to live but demands need not be met in toto."

525 E. 68th St. (21) (Dr. Hinsey).

THE ROLE OF MEDICAL EDUCATION IN CIVIL AND DEFENSE MOBILIZATION

John S. Patterson, B.S., Washington, D. C.

I am grateful for the opportunity to address this group, but let me assure you at the outset of these remarks that I do not speak as an expert on medical subjects. So, for the sake of the medical profession and my responsibility to the federal government, I should like very simply to express to you something of the urgent problem which each of us faces as we live in this age of continuing and accelerating changes.

Although I am not a medical man, I feel curiously at home in this gathering. Your concern with medical education and specialism parallels my concern over some of the major national security problems which we face today. That sounds like an enigma. Let me explain. The crux of your problem is the acceleration and proliferation of scientific knowledge and technological development. In the few years since 1940 we have made more scientific progress than in all man's history up to that time. When you write out a prescription today, the chances are 7 out of 10 that the medicine you call for did not exist 15 years ago.

Science is continuing to accelerate its onrush. If you are five years behind in your thinking now, you are more out of date than your fathers would have been if they had been 25 to 50 years behind in theirs. As you plan ahead to make medical education keep up with progress and to make physicians keep up with medical education, your problems multiply at a discouraging rate. You have to run faster and faster to stand still.

Consider, then, the broader problems of national security which we in the United States face and must learn to solve. Consider the significance of the growth in the power and range of missiles and in the number being produced. Consider the costs of providing adequate protection against fall-out throughout the United States. Consider our international problems: foreign aid and foreign bases, how to handle the Russians, and how to deal with the triple revolution in the underdeveloped areas—the revolution of rising economic expectations, of rising resentment at inequality, and of rising determination to be free and independent.

Our national security problems are formidable indeed. From the vantage point of my office the problem is one of learning to live in a new age—an age when we are under the constant threat of massive attack. And I say this irrespective of the current state of our relations with the Russians or of what their motivations may or may not be. As long as the arsenals of annihilation exist, so too does the threat exist.

We are living in the most perilous and dangerous period of man's history. We have learned how we can all die together, but we have not yet learned how we can all live together.

When you hear people criticize the inadequacy of civil defense preparedness, I hope you will draw the analogy with the problem of medical education. I hope you will remember that we, as a nation, have not really been able to keep up with the increases in the power of destruction during the last decade but we have come a long way from a standing start.

Deputy Director, Office of Civil and Defense Mobilization.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

Advances in Defense Preparedness

To illustrate some of the real progress we have made, let me summarize a few of the major developments in civil and defense mobilization readiness during the past year. I will tell you briefly about the creation of my new agency, about the National Plan for Civil and Defense Mobilization, the National Shelter Policy, and our radiologic defense program, and then I will comment on some of the recent developments of medical interest.

The most important action at the federal level was President Eisenhower's Reorganization Plan no. 1 of 1958. This merged the Federal Civil Defense Administration and the Office of Defense Mobilization and created the Office of Civil and Defense Mobilization in the Executive Office of the President.

It gave to the President directly the responsibility for all of the nation's nonmilitary defense. As commander-in-chief, he already had full military responsibility, and he now directs the total defense of the nation.

The President has delegated to the Office of Civil and Defense Mobilization those responsibilities that lie outside the military area. It eliminates duplication of effort and overlapping and conflict of interest and programs. It establishes unified federal guidance and direction. It has given new strength and stature, a proper standing in the federal government, to the critical mission assigned to us.

The most significant action which this new agency has taken to date was the issuance last October of the National Plan for Civil Defense and Defense Mobilization. This is the first time that an over-all plan for nonmilitary defense has ever been developed and circulated. Many months of effort and negotiation went into this plan, which will serve as a guide to the development of civil defense and defense mobilization programs at every level of government and in private organizations as well.

The plan, as issued, is only a beginning. It is just the skeleton and the central nervous system. The flesh and the organs are being developed now in the form of 40 annexes. Each will deal with a particular subject in more detail, describing goals, responsibilities, and jobs to be done. Several of these annexes will be of great interest to you, but particularly the National Medical and Health Plan.

Along with the work on these annexes, we are also readying new executive orders which will delegate specific planning and emergency responsibilities to other federal agencies. The Department of Health, Education, and Welfare, for example, will have the primary responsibility in the medical field.

Another great step forward last year was the adoption by the administration of a National Shelter Policy. This was based on a recognition that shelter from radioactive fall-out offers the greatest potential for saving lives in nuclear attack. The policy calls on citizens and directors of institutions of every sort to create shelter against the hazards of radioactive fall-out.

Each person is obligated to protect himself and his family from fall-out, just as he protects them from severe weather and from hunger. It lays upon federal, state, and local governments the requirement that they provide attack protection for their employees, and the same injunction extends to all institutions, schools, colleges, and hospitals.

The policy also contains the following provisions: (1) intensive education of every American on the possible effects of nuclear attack and the steps that he and his government can take to minimize them; (2) sampling surveys of existing structures to determine their shelter capabilities and what must be done to bring them to standard; (3) accelerated research to show how shelter may best be incorporated in both existing and new structures, to improve shelter design, and to reduce costs; (4) construction by the federal government of a limited number of prototype shelters for various geographical and climatic areas and for various types of construction, including schools and hospitals, insuring that they have practical peacetime uses as well; and (5) setting federal example by incorporating fall-out shelters in federal buildings hereafter designed, as an indispensable stimulation for state and local governments and private investment.

We have issued a general order to all federal departments and agencies to make the last provision effective. The other four require specific appropriations. Our request for funds to activate this policy last summer was caught in the merger of ODM and FCDA, and a tight congressional legislative program schedule. We are renewing our request to the new Congress because it is a sensible approach to a knotty problem and requires federal action.

The corollary of this policy is our program for building radiologic defense everywhere. In any attack, the immediate plotting of the wind and the location of nuclear bursts will give a general indication as to where to look for dangerous fall-out. Four times daily the weather bureau now provides OCDM and the state and local governments with observations of current wind directions and velocities.

Action to be taken by those under cover will be determined by the civil defense authorities in any locality after monitoring or measuring teams, using special radiologic instruments, locate the fall-out where it actually comes down and measure its radiation. A federal network of fixed monitor stations will use the facilities of all federal agencies. In 1959, the federal network will have available 900 fixed monitoring points over the nation, operating around the clock, and, in 1961, 3,000.

To provide for state and local monitoring, OCDM has bought 800,000 radiologic instruments, which are being distributed to state and local governments. Beginning in September, 1958, radiologic kits have been delivered to 6,000 high schools and colleges, with an additional 9,000 schools to receive them by June, 1959. Through the cooperation of the Department of Health, Education, and Welfare and the state education departments, science teachers in these schools are conducting instruction in the effects of radioactive fall-out, measurement, and monitoring. More than 1 million students will receive such instruction by June, 1959. Cities and states, within their police, fire, and health departments, are already conducting radiologic defense schools. More than 100,000 city and state employees will be instructed by June, 1959. I know that you will agree that these developments, present and projected, will enhance greatly our readiness as a nation to survive attack.

Program for the Medical Profession

Now let me turn to the specifically medical part of this job. I mentioned that we are preparing a delegation to the Department of Health, Education, and Welfare to take the leadership in this field. The proposal to make this comprehensive delegation was discussed fully by Governor Hoegh with the American Medical Association's Council on National Defense, and the A. M. A. heartily endorsed our action. The department will be responsible, through the Public Health Service, for planning and guiding emergency health and medical services, developing national medical casualty and preventive health services, developing a national emergency water supply plan, training emergency health and medical personnel, conducting research in medical and public health emergency measures, and continuously evaluating civilian health and medical resources and requirements.

The magnitude of the job for which the Public Health Service must plan is staggering. In the event of an attack, casualties in need of medical care could be measured in the tens of millions. Great numbers of people would be displaced with resultant increases in daily morbidity. Every able-bodied person would be working to the point of exhaustion. Those with chronic disease would be deprived of their usual attention in homes and clinics.

Premature births, miscarriages, and complications of delivery would increase. Accidental injuries would increase. With the disruption of utilities and the destruction of housing, extensive public health problems may be anticipated. Exposure to the elements and overcrowding in homes and mass-care shelters would intensify the threats of major epidemics of a wide variety of communicable diseases.

Chaos would be further increased by a lack of communications, transportation, and supplies. Finally, the widespread contamination by radioactive fall-out with effects lasting for days or weeks (combined with the delayed radioactive effects) completes a picture of great peril. In the face of this massive and terrifying problem, the health forces of the nation which must form the nucleus of the survivor care job are not now in a state of readiness from a civil defense standpoint for an emergency of these dimensions.

Under our delegation, the Public Health Service, working with the medical and nursing profession, medical educators, hospitals, and public health authorities, will give real impetus to our drive toward overcoming this lack of national health preparedness. The program will be based on the civil defense organization now in being. It will bring to bear the full resources of the Public Health Service in support of the medical profession and the health authorities. At the local level, the Public Health Service will utilize reserve corps to recruit and train physicians and other members of the health team in civil defense as it relates to medical care, preventive medicine, and special measures required in the defense against chemical warfare, biological warfare, and the problems of radioactive fall-out. Each trained person will provide the community with the competence to organize, plan, train, and rehearse its civil defense health personnel. These officers will work closely with state and local organizations already engaged in civil defense work. Thus, there will be a network of trained personnel to provide leadership, to give competent support to state and local organizations, and to coordinate community civil defense efforts.

Let me emphasize one point. Our ultimate limiting resource will be trained personnel. We can stockpile medical supplies and equipment, and we plan to. We cannot stockpile physicians. That is why strong programs of medical education are so vitally necessary.

OCDM, in the amount of $135,000, is backing the program of Medical Education for National Defense —the MEND program—on an equal basis with the Army, Navy, and Air Force, to acquaint instructors with medical problems anticipated in any national disaster so that graduates will be better prepared to assume the responsibilities of military or civil emergency medicine.

With the A. M. A., we have a $150,000 contract that is somewhat related to the MEND program and of great importance to the nation. The A. M. A. will study, develop, and recommend the planning, training, and operational organization needed for a national emergency care plan. We expect recommendations to cover (1) the use of professional and nonprofessional personnel of the medical and related professions before and immediately after attack; (2) the functions and responsibilities of the medical profession that may be delegated and performed by other health personnel; and (3) the training and education needed by health personnel, professional and nonprofessional, for wartime operational capability and the sorting of casualties.

Finally, we have given the National League for Nursing an $80,000 contract to develop a civil defense content for nursing education, both undergraduate and advanced. Massachusetts General Hospital, Skidmore College, Columbia University, and the University of Minnesota all are working on various phases of this 18-month undertaking.

I think the Association of American Medical Colleges is to be warmly commended because its members themselves recognize the need for developing simpler, faster ways of doing things. We stress the need for priorities of medical service and conservation of scarce skills in postattack planning, and the same principles must be applied in medical education as well as in other walks of life.

I also compliment the A. M. A. and the Association of American Medical Colleges for establishing the Liaison Committee on Medical Education for National Defense as a joint standing group for dealing with the medical education problems in a mobilization or a disaster situation. This should be of great service to us, as will your current joint program to send a questionnaire to all medical schools, to assist and encourage the schools to develop the information and do the planning necessary to preserve the faculty structure and function in a national emergency. The information this questionnaire will produce also will be most useful to OCDM in health manpower planning.

A very encouraging and constructive action to assure continuity of medical education has been put forward by the chief medical director of the Veterans Administration, Dr. William S. Middleton. He has stated that VA hospitals, particularly in nontarget areas, would be willing to plan with medical schools for the relocation of schools whose facilities are destroyed. A few schools, notably the University of Oklahoma, have made rather extensive plans with specific hospitals. We need more of this type of initiative.

All of these aspects of medical preparedness are important to our nation's emergency readiness. There are really only two basic elements to the kind of nonmilitary defense this nation must have: people, as individuals, and government, at all levels. Both need all of the help they can get, not only from the A. M. A., but from all other organized groups, professional or social.

We in government are doing our best for nonmilitary defense. We know that you—individually and collectively—will do likewise. No one could ask for anything more.

SPECIAL ARTICLE

NOMENCLATURE OF BLOOD CLOTTING FACTORS

FOUR FACTORS, THEIR CHARACTERIZATION AND INTERNATIONAL NUMBER

International Committee on Nomenclature of Blood Clotting Factors

Physicians often accuse basic scientists, chemists and physicists in particular, of using a strange language which no one outside their own subject can understand, but at least the majority of physicists or chemists can understand what others in their own field are talking about. The field of blood coagulation is one in which medical men and biological scientists have created such chaos that they do not even understand what other workers in the field are talking about, far less the clinician or the medical student.

To improve international communications is a worthy object at any time; to do so in the field of clotting factors has proved a task of major difficulty. To bring together the major workers not only from different countries but from the same country, hold them together, and persuade them of the importance of a simple understandable classification has been the problem for the chairman of the International Committee on Nomenclature of Blood Clotting Factors. This activity, of course, has much wider significance than just the field of blood clotting factors, and evidence for this wider significance has been the invitation by the National Advisory Heart Council of the United States to the members of this committee to or-

---

Members of the Committee are Drs. Irving S. Wright, New York Hospital (chairman); Prof. R. B. Hunter, Department of Pharmacology and Therapeutics, Queen's College, Dundee, Scotland (vice-chairman); T. Abe, Tokyo University Medical College; B. Alexander, Harvard Medical School, Boston; Tage Astrup, Biological Institute, Carlsberg Foundation, Copenhagen; Kenneth Brinkhous, University of North Carolina Medical School, Chapel Hill, N. C.; E. Deutsch, University of Austria Medical School, Vienna; P. Fantl, Baker Medical Institute, Alfred Hospital, Melbourne; H. Hartert, Medizinische Universitatsklinik (Ludolf-Krehl Klinik), Heidelberg, Germany; L. B. Jaques, Department of Physiology, University of Saskatchewan, Saskatoon, Canada; H. Jensen, U. S. Army Medical Research Laboratory, Fort Knox, Ky.; Prof. E. Jorpes, Karolinska Institute, Stockholm; F. Koller, Chefarzt der Medizinischen Abteilung der Krankenanstalt, Neumunster, Zurich, Switzerland; K. Lenggenhager, Direktor der Chirurgische Universitatsklinik, Bern, Switzerland; R. G. Macfarlane, Radcliffe Infirmary, Oxford, England; Willy Merz, University Clinic of Obstetrics and Gynecology of Lausanne, Lausanne, Switzerland; Pietro de Nicola, Pavia, Italy; Prof. P. A. Owren, Overlege, Rikshospitalet Medisinsk, Oslo; Alfredo Pavlovski, Buenos Aires; Armand Quick, Marquette University School of Medicine, Milwaukee; Laszlo Roka, Institute for Vegetativi Physiologie der Universitat, Frankfurt/Main Sud, Germany; Walter Seegers, Wayne University College of Medicine, Detroit; Pierre Soulier, Paris; and Marc Verstraete, Laboratoire de Physiopathologie, Louvain, Belgium (secretary).

ganize a series of international conferences within this field and to invite to these conferences young workers of exceptional promise so that they may listen to the discussion and benefit from the contact with their older colleagues from different countries in the world. The committee, therefore, is making a major contribution to international communications in medicine, and it is hoped that this type of activity will be seen more frequently as the world grows smaller and nations more fully accept the necessity for living and working together.

Work of the Committee

The story of this committee's work began at the first International Congress on Thrombosis and Embolism held in Basel in 1954, when the multiple names for identical substances emphasized that the problem of international communication was a serious one in this field. The International Committee for the Standardization of the Nomenclature of Blood Clotting Factors was established. Twenty-two members from 15 different countries were initially appointed. The list included the leading workers in the field, and most of the factors recently recognized had been discovered by these men. The first meeting brought into the open the fact that they had to a considerable extent created the problem, and they recognized that they had a moral and scientific responsibility to unravel it. It became clear that, though they had a paternal pride in the names of their choice, without their cooperation and compromise no progress could possibly be made. The efforts made by the members of the committee to yield their own strong positions for the common good have been noteworthy.

One of the first decisions made by the committee was that, whatever system of nomenclature was proposed, names should be avoided which implied an action by any factor. The reason for this had become clear when factors which previously had been given names implying function later were proved to have not that function but a different one. It was agreed that symbols should be used to designate blood coagulation factors until ultimately they were defined and identified in physical and chemical terms. However, certain essential physical and chemical data would have to be presented in support of the identity of any factor before the committee would give it an international symbol.

With further study and negotiation over a three-year period, it became evident that only a numerical system fully met these qualifications, and since some factors had already received Roman numerals in addition to their names it seemed logical to consider whether Roman numerals would be suitable as the international symbolic code, allowing the author freedom to use whichever synonym he wished. Thus, one would write factor V (proaccelerin), or factor V (labile factor). The Roman numeral would be intelligible in all languages, including the Oriental. The first four factors are widely known by their names and some identified chemically, and Roman numerals are perhaps less necessary. They are factor I, fibrinogen; factor II, prothrombin; factor III, thromboplastin (tissue); and factor IV, calcium. It seems likely that these names will continue in common usage, and in fact very few other names have been used for these factors.

One of the great problems facing the committee was to decide when sufficient evidence was available to justify any factor or activity being assigned a number. The following points were agreed on: 1. The minimal requirements for characterization of a clotting factor in whole blood, plasma, or serum shall be valid data on the reproducible effect on storage, adsorbability, inactivation by heating, and effect of pH. Additional chemical data are considered highly desirable if available. 2. A clinically identifiable state associated with an abnormality in the clotting mechanism shall be regarded as supporting the evidence for the lack or excess of a factor. 3. Methods of assay of physiological properties shall be listed. An appropriate selection of these methods will be considered as minimal for presentation of a factor before the criterion committee. In the case of previously undescribed factors the mechanism used for identification shall be clearly described by the author for study and possible acceptance by the committee.

Summary of Factors V, VII, VIII, and IX

The committee proposes to publish in detail elsewhere the criteria on which they have based their recommendation that four further blood coagulation factors should be recognized and assigned international symbols, namely, factor V, factor VII, factor VIII, and factor IX. A brief summary, however, is presented here.

Factor V.—Synonyms for factor V (Owren) include proaccelerin (Owren), labile factor (Quick), plasma ac-globulin (Ware and Seegers), thrombogene (Nolf), prothrombinase (Owren), prothrombokinase (Milstone), PPCF—plasmin prothrimbins—conversion factor (Stefanini), component A of prothrombin (Quick), prothrombin accelerator (Fantl and Nance), and cofactor of thromboplastin (Honorato).

Deficiency of this factor results in a hemorrhagic diathesis which is probably inherited and has been described as a parahemophilia or hypoproaccelerinemia. The first cause was recognized and described by Owren[1] in a beautiful study carried on under the most adverse conditions during the Nazi occupation of Norway, while Owren was at the same time an active member of the underground resistance. Several additional cases have since been described. This factor seems necessary for the formation of the prothrombin converting substance in the blood and in tissue extracts. Other interesting properties are fully described in the literature.[2]

Factor VII.—Synonyms for factor VII (Koller) include proconvertin (Owren), SPCA—serum prothrombin conversion accelerator (deVries, Alexander), stabile factor (Stefanini), cofactor V (Owren), serozym (Bordet), kappa factor (Sorbye and Dam), prothrombinogen (Quick), cothromboplastin (Mann and Hurn), serum accelerator (Jacox), prothrombin conversion factor (Owren), and prothrombin converting factor (Jacox).

Factor VII plays a part in the production of at least three groups of abnormal states: 1. A congenital deficiency may produce hemorrhagic phenomena with purpura and bleeding from the mucous membranes. Many such cases have been described. 2. Acquired deficiency may occur in liver disease, in vitamin K deficiency, in the immediate neonatal period, and after the administration of prothrombinopenic agents, such as the coumarin derivatives used in anticoagulant therapy. 3. Excesses of factor VII have been found in certain states associated with a high incidence of thromboembolism, such as the third trimester of pregnancy. The level of this substance in the blood is species specific. Deficiency results in a quantitative prolongation of the one-stage prothrombin time test. Factor VII accelerates the conversion of prothrombin to thrombin in the presence of tissue thromboplastin, factor V, and calcium (Ca^{++}). It does not accelerate the interaction of platelet factor 3 and factors VIII and IX. It cannot rectify retarded coagulation due to factor V deficiency. It is not essential for thromboplastin generation in the coagulation of blood. Other interesting properties are fully described in the literature.[3]

Factor VIII.—Synonyms for factor VIII (Koller) include antihemophilic globulin (Patek and Taylor), antihemophilic globulin A (Cramer), AHF—antihemophilic factor (Brinkhous), PTF—plasma thromboplastic factor (Ratnoff), plasma thromboplastic factor A (Aggeler), TPC—thromboplastic plasma component (Shinowara), facteur antihemophilique A (Soulier), thromboplastinogen (Quick), prothrombokinase (Feissly), platelet cofactor (Johnson), plasmokinin (Laki), and thrombokatilysin (Leggenhager).

Factor VIII deficiency represents the classic hemophilia A, well known as the hereditary hemorrhagic disease which occurs almost exclusively in males but which is female sex-linked. The degree of factor VIII deficiency varies from patient to patient. Hemorrhage occurs in any tissue after minor injuries and is frequently serious. Factor VIII enters into the early stages of coagulation with factor IX and calcium ions to produce an intermediate product which reacts with platelet factor 3. The result of this reaction in the presence of factor V is an active agent in prothrombin conversion. It is essential in the formation of blood thromboplastin. A deficiency (1) prolongs the clotting time, (2) diminishes the thromboplastin formed, and (3) diminishes the prothrombin conversion.[4]

Factor IX.—Synonyms for factor IX (Koller) include Christmas factor (Biggs and Macfarlane), PTC—plasma thromboplastic component (Aggeler), antihemophilic globulin B (Cramer), plasma thromboplastic factor B (Aggeler), plasma factor X (Shulman), and facteur antihemophilique B (Soulier).

Factor IX deficiency produces hemophilia B or Christmas disease, named after the now-famous patient of Biggs and Macfarlane. This is usually a severe hemorrhagic disorder resembling hemophilia A and inherited in the same way. Studies of this disorder led to the discovery of factor IX. Factor IX, like factor VIII, is essential for the formation of intrinsic blood thromboplastin. It probably enters into reactions leading to the formation of this thromboplastin with calcium ions and factor VIII, an intermediate product which then reacts with platelet factor 3 and factor V. It influences primarily the amount of thromboplastin formed and not the rate of its generation.[5]

New Factors Under Consideration

A number of additional plasma and serum factors have been described by various workers who believe they have established that they play a role in physiological clotting of blood. These factors are now under study by the committee, and if the evidence indicates that the claims are valid they will be assigned a Roman numeral.

The ultimate contribution of this committee to medical understanding and education will depend on the willingness of educators, editors, and authors to adopt this system in their day-to-day efforts to create the medical thinking and literature of the future.

DIAGNOSTIC PROBLEMS

PROGRESSIVE PULMONARY INSUFFICIENCY IN A 57-YEAR-OLD WOMAN

Clinical Pathological Conference (PM 1346-58), Oct. 9, 1958, from the Department of Pathology and the Hektoen Institute for Medical Research of Cook County Hospital, Chicago, presented for publication by Daniel S. Kushner, M.D., and Paul B. Szanto, M.D.

Clinical Data

A 57-year-old woman was admitted to Cook County Hospital on June 27, 1958, with complaints of profuse night sweats, intermittent high fever, and weakness of three weeks' duration. She also complained of headache, exertional dyspnea, and slight orthopnea, but no edema. She had had bronchial asthma for 32 years with intermittent symptoms, well controlled with ephedrine and proprietary drugs. History revealed measles, mumps, chicken pox, and whooping cough in childhood; several hospitalizations between 1928 and 1937 for bronchial asthma; and an admission for "bronchial pneumonia." She had been told she had a fibroid uterus, but she had refused an operation. Menarche occurred at the age of 9; menses had been regular, and her last menstrual period had occurred 12 years previously. She had been pregnant once but aborted. The patient had been born in Mississippi and had lived in Chicago for 26 years. She had worked for four years (about 1929) running machines in a dusty factory "making glue for paper work."

Physical examination disclosed an extremely obese, dyspneic, middle-aged woman with a relentless, violent, nonproductive cough. Her skin was dry and sallow. She was cyanotic, but had no clubbing of the digits. Her blood pressure was 106/70 mm.Hg., pulse 120 per minute, respirations 40 per minute, and temperature 102 F (39 C). Her scalp hair was "dry and falling out." Her facial features were masculine and hirsute. Funduscopic examination was negative. Diffuse rales and wheezes were heard throughout both lung fields. The heart was not enlarged; apical and radial rates were 120 per minute and regular, and no murmurs were heard. Her abdomen was obese, and no organs or masses were palpated. The extremities were normal; neurological examination and pelvic and rectal examinations gave negative results. A stool benzidine reaction was negative.

Urinalysis was normal. The hemoglobin level was 12.8 Gm. per 100 cc. (82%); the leukocyte count was 9,400 per cubic millimeter, with platelets adequate; the differential count revealed 44% neutrophils, 3% band forms, 10% eosinophils, 1% basophils, 32% lymphocytes, 7% monocytes, 1% myelocytes, and 2% metamyelocytes; 1+ anisocytosis, polychromatophilia, and 2+ toxicity were noted. A subsequent hemogram, on July 28, 1958, revealed a hemoglobin level of 16.1 Gm. (103%); leukocyte count 15,200 per cubic millimeter, with a differential count of 87% neutrophils, 1% eosinophils, 9% lymphocytes, and 3% monocytes; 1+ anisocytosis and toxicity. The hematocrit reading was 58% and 56% on two occasions. L. E. cell preparation was negative. Prothrombin time was 16 seconds (control 12 seconds). The blood Kahn reaction was negative. The blood urea nitrogen level was 12 mg. per 100 ml., total protein 6.7 Gm. per 100 ml., gamma globulin 1.32 Gm. per 100 ml., calcium 11.4 mg. per 100 ml., and cholesterol 148 mg. per 100 ml.; the sodium level was 142 mEq. per liter, potassium 7.3 mEq. per liter, and chloride 98 mEq. per liter; the icterus index was 8, cephalin flocculation 0, thymol turbidity 2.4 units, and carbon dioxide–combining power 32 ml. per 100 ml. Serum electrophoresis revealed only a slight increase in alpha$_2$ globulin.

Dr. Kushner is Associate Director of Medical Education, Cook County Hospital, and Instructor in Medicine, Northwestern University Medical School; Dr. Szanto is Director, Department of Pathology, Cook County ital, and Professor of Patholgy, Chicago Medical School.

strong is Director of Medical Education, Cook County Hos- ssor of Medicine, University of Illinois.

Electrocardiograms showed a semivertical electrical axis with clockwise rotation and prominent broad P waves, especially in leads 2 and AVF.

Roentgenogram of the chest revealed that the heart size was normal. The pulmonary artery segment was enlarged. Many miliary-sized nodules were scattered uniformly throughout both lungs. In addition to the small nodular densities, a homogeneous density in the left lung spared the left apex and left base. On July 7, the small nodular lesions appeared less discrete. On July 21, the small nodular lesions appeared slightly larger. On July 30, the homogeneous density in the left lung appeared denser. On Aug. 22, there was confluence of the nodular lesions in the right lung. The homogeneous density in the left lung appeared still denser.

Smears and cultures of bronchial secretion and sputum on three different occasions gave negative results for acid-fast bacilli. Mycologic culture of the sputum was negative. A tuberculin skin test gave positive results (1:10,000); skin tests with histoplasmin, blastomyces vaccine, and coccidioidin gave negative results. Arm-to-tongue circulation time (with use of sodium dehydrocholate [Decholin sodium]) was 8 to 10 seconds.

Bronchoscopy was negative. Pulmonary function studies on July 17 (see table) indicated marked arterial unsaturation and hyperventilation. Attempts to measure oxygen diffusing capacity were unsuccessful. Cardiac catheterization revealed pulmonary and right ventricular hypertension and elevated cardiac output but no evidence of heart failure. Further pulmonary function studies were not completed because of the patient's respiratory distress. Examination of a right scalene lymph node removed by biopsy revealed chronic lymphadenitis.

After an initial slight improvement, the hospital course was one of inexorable progression of dyspnea, cyanosis, and paroxysmal cough, productive of greenish sputum in small amounts, vague chest pain, increasing weakness, fatigue, anorexia, nausea, mental confusion, and faintness. The patient was generally afebrile, with occasional temperatures recorded at 100 F (37.8 C) and a single elevation to 101.2 F (38.5). She was treated with penicillin, streptomycin, isoniazid, para-aminosalicylic acid, pyridoxine, intermittent positive-pressure oxygen inhalation, ephedrine, epinephrine, aminophylline, codeine, potassium iodide, promazine, and aluminum hydroxide. Steroid therapy was instituted on July 26 with corticotropin and hydrocortisone and was subsequently maintained with cortisone. Considerable euphoria was its only apparent effect.

The patient was digitalized on Aug. 15. Her respiratory rate remained above 40 per minute, with forced, prolonged expirations, somewhat relieved symptomatically by aminophylline. There was tachycardia (pulse rate 140 per minute), tachypnea (respirations 46 per minute), and increased cyanosis. The patient died on Aug. 29, 1958, after a duration of illness of 11 weeks.

Clinical Discussion

Dr. S. Howard Armstrong Jr.: We have to consider the problem of a 57-year-old woman with an acute illness, characterized by chills, fever, and night sweats, suggesting an acute infection superimposed on at least 30 years of chronic respiratory disease.

She was born in one of the southern states and, at the time she is said to have acquired bronchial asthma, she had had a four-year exposure to a dusty factory where she worked making glue. What relationship does the paper industry bear to chronic pulmonary disease? The cellulose fiber itself has not been incriminated in the development of pneumoconiosis. A chronic pneumonitis is associated with both the sugar cane cellulose fiber and the cotton cellulose fiber. Bronchial asthma has been rarely associated with prolonged exposure to cotton cellulose. However, paper is made from wood, and wood is very sporadic in its capacity to produce allergy. This varies with wood species, and cabinet-makers do occasionally develop allergic symptoms. On the other hand, exposure to the fine sawdust of most woods results in nothing more than sneezing and coughing. Red cedar wood has produced allergic *manifestations but is not often used in paper.*

Physiological Data Obtained by Right Heart Catheterization

	Observed	Normal
Arterial blood		
Oxygen saturation, %	62	96-98
Carbon dioxide content, vol. %	45	45-50
Pressures, systolic/diastolic, mm. Hg		
Right atrium	12/0	0 to 3/0 to —3
Right ventricle	73/2	18 to 30/4 to 5
Pulmonary artery	73/27	18 to 30/6 to 12
Flow, cardiac output, liters/min.	8.05	5.3-7.0
Ventilation		
Oxygen uptake, ml./min.	361	225-300
Ventilation, *liters/min.*	11.2	5.6-7.5
Ventilatory equivalent	3.1	2.5

With regard to glue, the older varieties were made from gelatin, which is not an allergenic substance and, more recently, casein and urea resins. Only more recently have other allergenic materials come into the glue industry. These are the synthetic epoxyresins which require an activator and which do cause apparent allergic reactions in the skin and respiratory tract. Finally, in paper factories, the processing of fibers is usually a wet process, and the dust content is not high.

Historically, the patient was said to have had uterine fibroids, suggesting the remote possibilit *multiple pulmonary abscesses from necr* were infected degenerated fibroids. The pa lining t in some ar and hirsutism at least raise the question of adrenal cortical hyperfunction (Cushing's syndrome). Although she had 12% eosinophils, the hypereosinophilia of polyarteritis nodosa and of allergic disease cannot be as readily eliminated by the administration of corticosteroids as can the normal eosinophilia. Therefore, while one cannot use the eosinophilia to exclude a state of hyperadrenal corticism, it is quite possible that the obesity and hirsutism are on the more common hereditary or familial basis. I wonder about the character of her respirations.

Dr. George River: Her respirations were shallow and rapid. There was no evidence of supraclavicular retraction.

Dr. Armstrong: Then she probably did not have bronchiolar obstruction. Apart from an initial temperature of 102 F (38.9 C), her course was quite afebrile. Her heart was apparently of normal size, and she had little roentgenographic evidence of cor pulmonale. Bacteriologically, despite the fact that she had a constant, unrelenting, hacking cough, smears and cultures of both sputum and bronchial secretion revealed neither tubercle bacilli nor fungi. She did not expectorate material suggesting chronic bronchiectasis, lung abscess, or necrotic carcinoma. Skin tests gave negative results, except for the tuberculin test, which informed us that she had at one time responded immunologically to a tuberculous exposure. Some patients with generalized sarcoidosis (Boeck's sarcoid) have been known to develop a terminal miliary tuberculosis with a positive tuberculin skin reaction, and, therefore, one cannot exclude sarcoidosis on the basis of a positive Mantoux reaction. But this would be most peculiar miliary tuberculosis in a patient who had two months of specific antimicrobial therapy, with not only no change but actual progression of the roentgenographically defined pulmonary lesions.

With regard to the cardiopulmonary physiological evaluations, the first simple test gave a circulation time of eight seconds. This is unusually rapid and, together with the desaturation of the arterial blood (62% oxygen saturation) in this patient, forces consideration of the differential diagnosis between a pulmonary diffusion barrier with right heart failure and the possibility of a shunt. The remainder of the data showed a cardiac output of 8 liters, which, expressed in terms of cardiac index, would probably be just above the upper limits of normal. The right ventricular and pulmonary arterial pressure were elevated.

Among obstructive diseases of the pulmonary arteries, one must consider multiple pulmonary emboli, for which there is no evidence here. In sum, the physiological data, interpreted in the light of clinical findings, suggest that the arterial oxygen [illegible] and pulmonary hypertension are the result of a diffuse parenchymal pulmonary process, offering some barrier to both gaseous diffusion and blood flow.

With the etiology undefined, after the course of various therapeutic trials, the pulmonary lesions tended to become larger and more confluent. The adrenal corticoids were probably given for the remote possibility of polyarteritis of the lung, with eosinophilia. Many unrelated types of pulmonary parenchymal disease of undefined etiology, including berylliosis, sarcoidosis, and the Hamman-Rich syndrome,[1] do respond somewhat to corticosteroid therapy, especially if treated early. The commonest lesion for a patient, even a woman in her 50's, with this history and findings, is carcinoma of the lung. Carcinoma of the lung may be silent while infection occurs behind it, resulting in night sweats, chills, and fever. A single or multiple abscesses may become walled off. Antibiotics result in only temporary remission; then the process progresses. Carcinoma of the lung does not necessarily produce a hematogenous spread; it may undergo miliary lymphatic spread, producing the type of lesions described roentgenographically in the patient.

In summary, this patient is an old asthmatic who has had some degree of pulmonary hypertension and a moderate amount of pulmonary arteriosclerosis. She more recently acquired carcinoma of the lung and developed lymphatic dissemination, which is much more likely to accentuate asthmatic symptoms than hematogenous dissemination with big nodules of metastatic tissue.

Dr. William Meszaros: The roentgenographic findings suggested diffuse miliary lung lesions with progressive confluence; miliary tuberculosis or carcinomatosis would produce this appearance. The homogeneous infiltration in the left lung is compatible with either chronic pneumonitis or neoplastic disease. From the roentgenologic point of view, an analysis of nodular pulmonary lesions includes consideration of inflammatory infections of bacterial, viral, or fungus etiologies. As far as neoplastic diseases are concerned, miliary metastases are quite common. The large lesion in the left lung would be hard to reconcile with metastasis. The absence of pleural effusion and the patient's rapid deterioration speak against inflammatory lesions, including tuberculosis. I would think the most likely possibility is bronchogenic carcinoma.

Dr. Louis Feldman: Within one month, this patient developed polycythemia. This again raises the question of a pulmonary diffusion barrier versus a cardiac shunt.

Dr. William Buckingham: Unfortunately, attempts to do a diffusion study using the Riley technique were unsuccessful because of the poor condition of the patient.

Dr. Earl Zaus: From the point of view of the radiologic changes, tuberculosis would not be the first thing to consider. Outstanding considerations would be (1) pulmonary adenomatous carcinoma, (2) lesions that belong to the interstitial fibrosing group, (3) fungus infection, and (4) the collagen diseases. This type of picture is not common in collagen disease. In 111 reported cases of polyarteritis nodosa, 14 of the patients had characteristic pulmonary findings of granulomatous lesions, not resembling those seen here. The same 14 also had a characteristic clinical picture.

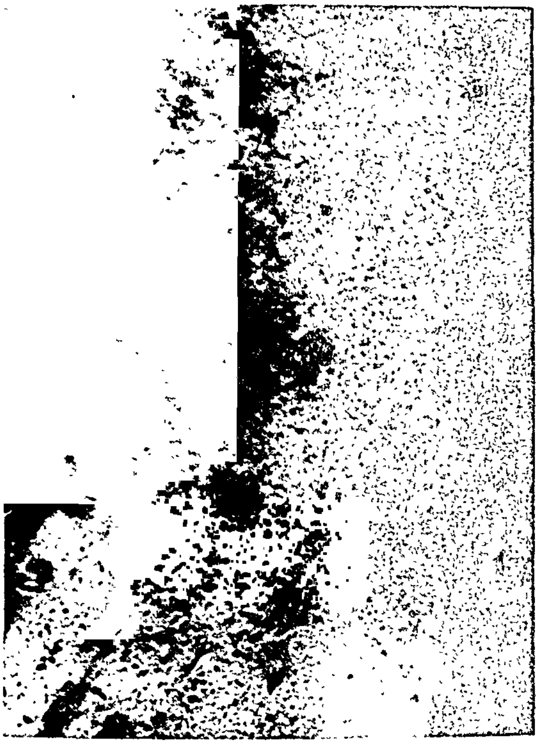

Fig. 1.—Extensive consolidation of lung seen on cut surface. Honeycombed appearance is due to emphysema.

Question: Why wasn't biopsy of the lung done, as the easiest way to confirm a diagnosis?

Dr. River: We had planned to do a lung biopsy, but the patient initially refused, and subsequently her condition rapidly deteriorated.

Clinical Diagnosis.—The clinical diagnosis was bronchogenic carcinoma with diffuse lymphangitic spread, superimposed on chronic bronchial asthma with pulmonary hypertension and pulmonary arteriosclerosis.

Pathologist's Report

Dr. Paul B. Szanto: At autopsy the heart was moderately enlarged (380 Gm.), due to moderate hypertrophy of the right ventricle. Histologically, the epicardium showed some lymphocytic infiltration. The liver (1,200 Gm.) and spleen (125 Gm.) showed passive congestion. The uterus was enlarged with fibroids. The adrenals were normal.

The lungs were heavy (1,200 Gm.). The pleura was smooth and shiny. The mucosa of the bronchial tree was injected; no endobronchial lesion was present. The consistency of the lungs was uniformly firm due to diffuse consolidation, and the cut section of both lungs showed a brown-pinkish-tan color (fig. 1). Large sections taken from the various segments of all lobes of both lungs revealed a fairly uniform involvement (fig. 2 and 3) of the emphysematous lungs. Only scattered small foci of distended air-containing alveoli remained uninvolved.

The lining epithelium of the bronchi was everywhere well preserved. The basement membrane of the bronchi was thickened, as seen in instances of long-standing bronchial asthma. The muscular layer was also thickened and infiltrated by lymphocytes as evidence of chronic bronchitis. Some pulmonary arteries showed intimal thickening with extreme narrowing of the lumen. The lumen of one medium-sized pulmonary artery was almost occluded by an organized thrombus.

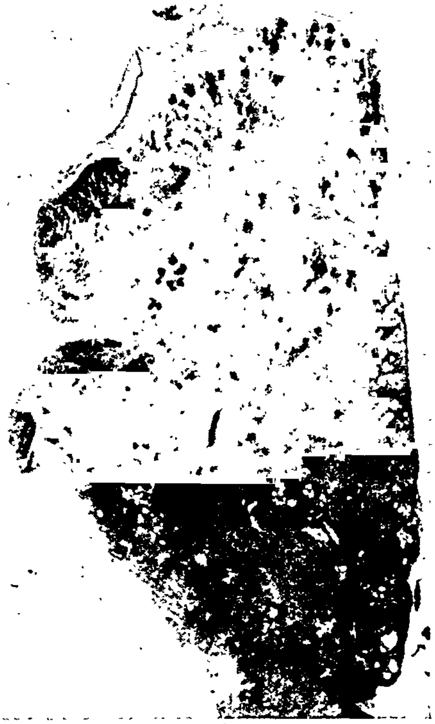

Fig. 2.—Section through apical segment, showing uniform infiltration of alveoli. A few dilated alveoli appear in periphery of section.

The bronchi of the third order showed clus[illegible] of tumor cells invading their walls but not invol[illegible] the mucosa proper. All the alveoli were unifor[illegible] involved and were lined by columnar epithel[illegible] cells of variegated appearance, with pleomor[illegible] and hyperchromatic nuclei. Occasionally, there were papillary projections of the tumor cells lining t[illegible] alveoli (fig. 4). The alveolar septums in some ar were delicate, whereas others showed fibrous thickening. It should be pointed out that the slender connective tissue septums do not necessarily represent alveolar septums; septate stroma has been observed also in lymph node metastases of carcinomas of this type. The lumen of the bronchioles contained numerous desquamated columnar epithelial cells, *intermingled with pleomorphic tumor cells.*

On the basis of these findings, this is an alveolar cell tumor or, more properly, bronchiolar cell carcinoma, since it originates not from the alveolar but from the bronchiolar lining cells. Distant metastasis of this type of tumor is not frequent. In this case, the bronchial lymph nodes were not involved, but the left paratracheal lymph nodes were moderately enlarged due to replacement by tumor tissue.

We have recently observed in another case a circumscribed, nodular, and histologically better differentiated type of bronchiolar cell carcinoma in a 77-year-old woman. The apical segment of the left lower lobe revealed an indistinctly outlined gray-white gelatinous tumor measuring 2 by 2 cm. Microscopically, the alveoli in the area of the tumor were lined by high columnar epithelial cells, uniform in appearance, with the nuclei at the base of the cells (fig. 5 and 6).

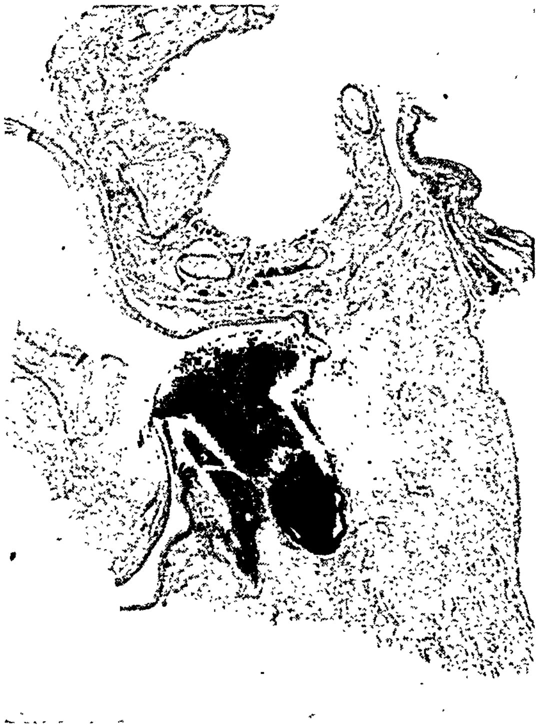

Fig. 3.—Uninvolved bronchus with uniform infiltration of adjacent alveoli.

The Pathological Diagnosis.—The pathological diag-[illegible] was bilateral diffuse bronchiolar (alveolar [illegible]inoma; secondary diffuse pulmonary fibro-[illegible]trophy of the right ventricle; metastasis to the tracheobronchial lymph nodes; passive congestion of liver and spleen; obesity; and uterine fibromyomas.

Comment

Dr. Szanto: Malignant tumors of the lung are classified as (1) primary epithelial tumors, including bronchial adenoma (carcinoid and cylindroma), bronchogenic carcinoma (epidermoid carcinoma adenocarcinoma, undifferentiated large cell carcinoma, and undifferentiated small [oat cell] carcinoma), and bronchiolar carcinoma; (2) sarcoma including undifferentiated (pleomorphic) sarcoma differentiated fibrosarcoma, leiomyosarcoma and chondrosarcoma; (3) carcinosarcoma; (4) mesothelioma; (5) lymphoma (lymphocytic lymphosarcoma and Hodgkin's disease); and (6) metastatic carcinoma and sarcoma. (Bronchial adenomas are histologically benign tumors. The cylindrical type of adenoma has a tendency toward invasion of the wall. Bronchial adenomas may metastasize to the regional lymph nodes.)

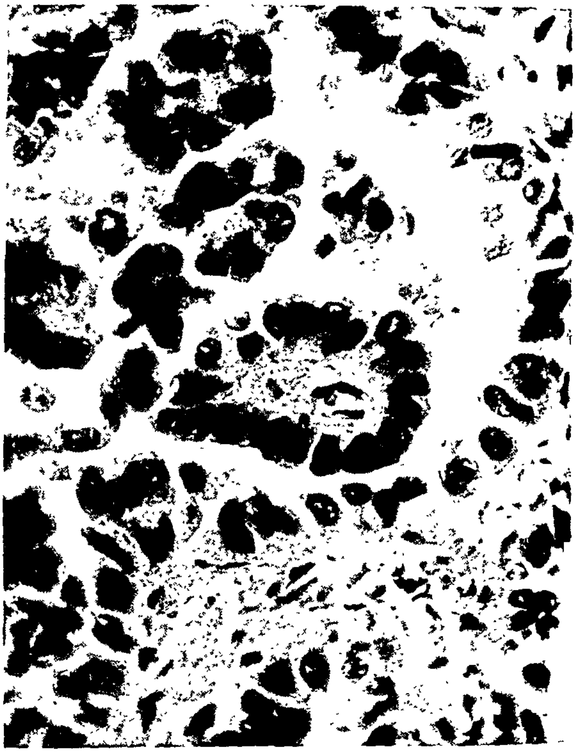

Fig. 4.—Lining of alveoli by columnar epithelium with large pleomorphic, hyperchromatic nuclei.

Adenocarcinoma of the bronchus may possibly originate from large bronchi or from smaller segmented bronchi in the periphery of the lung; then the differential diagnosis between peripheral adenocarcinoma and bronchiolar carcinoma may become difficult. I would stress, however, three points of importance: 1. Adenocarcinoma of the bronchi metastasizes early and widely by the hematogenous route; distant metastasis from bronchiolar carcinoma is rare, as pointed out before. 2. Bronchiolar carcinoma is usually better differentiated than adenocarcinoma. 3. Bronchiolar carcinoma fails to show necrotic changes.

The term bronchiolar adenoma, one of the many synonyms of bronchiolar carcinoma (primary multiple alveolar cell tumor, pulmonary alveolar adenomatosis, alveolar cell carcinoma, diffuse lung carcinoma, diffuse primary alveolar carcinoma, multicentric alveolar cell carcinoma, papillary gelatinous alveolar carcinoma, and bronchiolar carcinoma), has been used [2] because of the relatively benign histological appearance of the tumor, but I would stress that despite their benign histological appearance, these tumors are always malignant. The etiology of alveolar cell carcinoma is intriguing because a similar type of pulmonary lesion has been observed in sheep as a rapidly progressive process, endemic to South Africa, interpreted as a viral infection. It is known as jagziekte, and it results in death of the affected animal two to eight months after onset. It is stated that bronchiolar carcinoma makes up about 5% of all lung tumors in men, and in our own material it approximates this incidence.

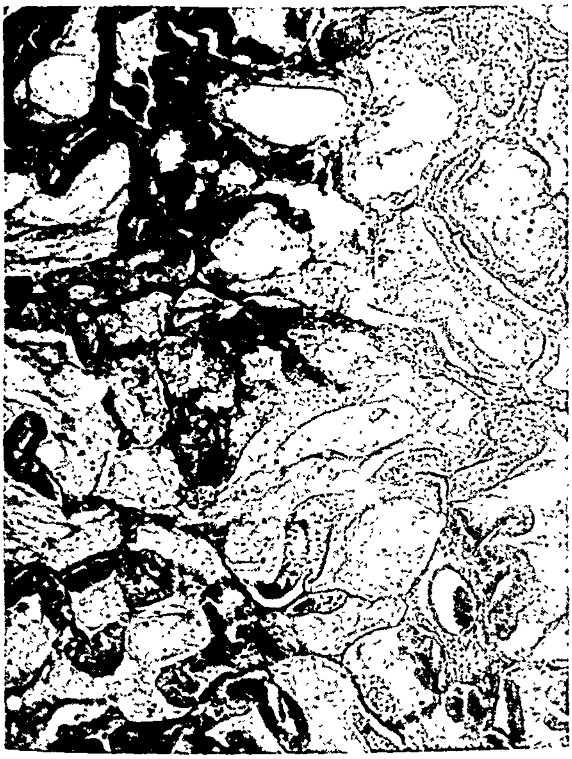

Fig. 5.—Lining of alveoli by high columnar cells with uniform nuclei, pale cytoplasm, and mucinous material in alveolar lumens.

Bronchiolar cell carcinoma presents a pathological, anatomic, and clinical entity, occurring with equal frequency in males and females. The clinical symptomatology is dominated by the expectoration of large amounts of mucoid sputum (daily, 100 cc. or more with admixture of streaks of blood), stubborn irritating cough, dyspnea, cyanosis, and night sweats. In the expectorated material, frequently one has the opportunity to demonstrate malignant cells. In this case, the characteristic expectoration of odorless, watery mucus was absent.

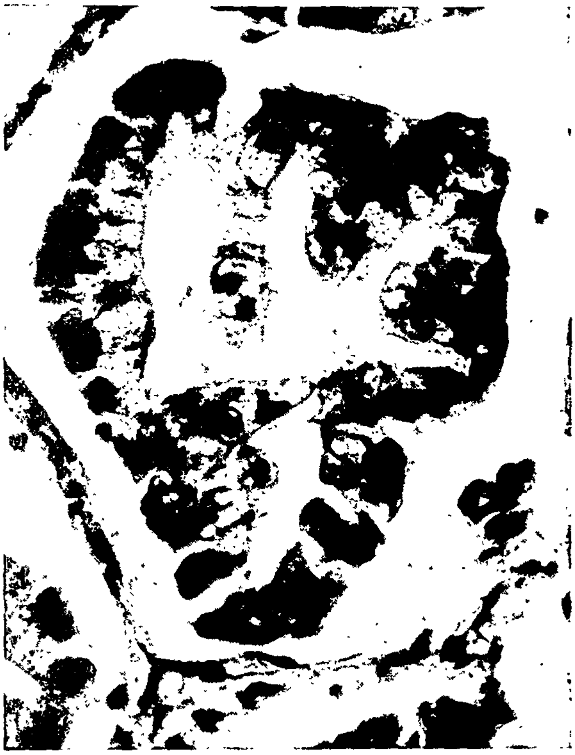

Fig. 6.—High-power view of lining of alveoli by high columnar epithelial cells with uniform nuclei, pale cytoplasm, and mucinous material in alveolar lumens.

Grossly, the tumor may be segmental (circumscribed) or diffuse, involving a large part of one or both lungs. The diffuse type of bronchiolar carcinoma (as in the case under discussion) may be of multicentric origin, or it may rapidly spread from a single focus by both bronchogenic and lymphogenic dissemination. The question of unicentric versus multicentric origin has important therapeutic implications. Doubtless, the importance of multicentric origin of this tumor has been overemphasized in the past. In all probability, bilateral involvement of the lung usually results from bronchogenic and lymphogenic spread from a rapidly metastasizing carcinoma of unicentric origin.

STRENGTHENING THE SINEWS OF UNDERSTANDING

IN THIS issue (page 280) is published the address of the President of the American Medical Association, Dr. Gunnar Gundersen, delivered before the recent annual meeting of the Federation of State Medical Boards.

Dr. Gundersen has been widely quoted in the press as advocating that steps be taken in the immediate future to insure that physicians keep abreast of medical advances by requiring them to be reexamined periodically in order to retain their licenses to practice. A large response to the news references has come from physicians.

Dr. Gundersen was not certain which method was best to stimulate physicians to continue their education. He said: "This is a matter for careful study by all concerned." Dr. Gundersen's suggestion is not without precedent. In 1937, then A. M. A. President J. H. J. Upham said to the House of Delegates, "There is already a trend toward compulsory evidence of postgraduate improvement. . . . In several states there are laws requiring annual registration of physicians. . . . There is the possibility that the next step might be as a requirement for renewal of licensure evidence of familiarity with the developments in medicine by five or ten year periodic examinations."[1]

The American Medical Association was founded [illegible] 1847 because of the concern of leaders in the [illegible]fession with the low standards of medical education and of medical practice at that time. The Association ever since has steadfastly initiated and continued activities whose goal has been the elevation of standards of medical education at all levels to assure the highest attainable quality of medical care.

The profession has supported increasing programs of research—programs that have harvested an abundantly rich yield of new knowledge. Millions of dollars and the skills of thousands of physicians and other scientists pour into the research effort to develop new knowledge applicable in medicine to disease prevention and to the better diagnosis and therapeusis of disease.

Research is the means of producing new knowledge, but education is the means of its distribution. It is entirely appropriate that the medical profession be concerned with the distribution of new knowledge as thoroughly and as broadly as possible. Until advances in medicine are applied by physicians in patient care, they are ineffectual.

The use of the more significant advances requires a new synthesis of knowledge and a deepened understanding of disturbed biochemical and metabolic relationships. Such discoveries can be two-edged tools—capable of inflicting harm when used with insufficient understanding or of producing great benefit when used appropriately. Often the most significant advances are new insights into the basic processes of normal and disturbed body function, thus making medicine more rational and less empirical. Such discoveries must be fitted into the fabric of other related knowledge in each physician's mental armamentarium. Obviously initial education and training, no matter how excellent, is only a beginning of medical education, *not the end.*

The problem is how to maintain, in the light of ever-increasing knowledge, the superior competence with which doctors enter the profession. For the sake of the public it serves, how can the medical profession in active practice best be assisted to remain close to the summit of knowledge available?

As the profession long ago took the initiative in elevating the standards of education and fitness required to enter practice, now it is coming to grips with new challenges, among which is that of closing the gap between research and its application in practice. As the tempo of research accelerates, its effective dissemination becomes more urgent.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. Include the address label clipped from your latest copy of The Journal, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

ORGANIZATION SECTION

TELEVISION SERIES FOR THE ATLANTIC CITY MEETING

A series of four half-hour television programs summarizing top scientific events will be a feature of the American Medical Association's 108th Annual Meeting in Atlantic City. Originating at 5:30 p. m. Monday through Thursday from a special studio in Convention Hall, the American Medical Association's "Bulletin of the Air" will be seen in the Philadelphia–Atlantic City area over WFIL-TV, channel 6. On each telecast, meeting participants who made scientific "news" during the day will present capsule reports to the television audience. The programs—featuring Philadelphia newscaster Taylor Grant—will be designed to keep physicians informed of newsworthy events and at the same time show the general public what goes on at an A. M. A. meeting. Film recordings made of the "live" telecasts will be edited into motion picture "Highlights of the 108th Annual Session" for fall distribution to medical meetings throughout the country. Both the television programs and the filmed "Highlights" will be presented by the American Medical Association in cooperation with Merck, Sharp & Dohme. Serving as consultant in selection of program material is Dr. Stanley P. Reimann, Philadelphia, Chairman of the A. M. A.'s Council on Scientific Assembly.

GOLF TOURNAMENT DURING ATLANTIC CITY MEETING

The 43rd Annual Tournament of the American Medical Golfing Association will be held at the Seaview Country Club, Absecon, N. J., on June 8, 1959. The hours of teeing off are from 8 a. m. to 2 p. m. All male members of the A. M. A. are eligible for membership. The tournament fee of $25 will include green fees, luncheon, banquet, and prizes. New fellows pay an enrollment fee of $3 for lifetime membership. Private cars or taxis from Atlantic City are recommended as the best means of transportation. Arrangements may be made to pick up groups at their hotels in Atlantic City. Reservations and checks may be sent to Dr. Mario A. Castallo, 1621 Spruce St., Philadelphia 3.

GOVERNMENT SERVICES

ARMY

New Surgeon General.—Major Gen. Leonard D. Heaton has been named surgeon general to succeed Major Gen. Silas B. Hays whose term expired on April 30. General Heaton, who was commanding general of Walter Reed Army Medical Center, operated on the President for ileitis in 1956.

VETERANS ADMINISTRATION

Cord Injury Center.—One of the most complete hospital facilities ever designed for care of patients with spinal cord injuries is now in operation at the Veterans Administration hospital at Long Beach, Calif. This spinal cord injury center cares for 205 patients in the hospital and for 980 outpatients, and it has a separate section to handle visits of former patients who are working at various jobs in the area. The facilities for paraplegic and quadriplegic patients occupy the first floor and lower level of a new 296,000-sq. ft. expansion of the hospital, which replaced 20 temporary buildings on the site. The upper floors of the four-level expansion are used for general hospital activities.

Doctors' and other specialists' offices are located on one side of the first floor corridor of the central core, with treatment facilities and consultation rooms directly across the hall from each office. Patients' rooms and ward areas are located in the five wings of the first floor. Medical and vocational rehabilitation areas are in the lower level. The center has an exercise clinic, a cystoscopy clinic, a central bath area, a therapeutic pool, and specially designed brine tanks.

PUBLIC HEALTH SERVICE

Division of Water Pollution Control.—The Secretary of Health, Education, and Welfare has created a Division of Water Pollution Control. In the past two years, water pollution control activities have been carried out in the Water Supply and Water Pollution Control Branch of the Division of Sanitary Engineering Services. The new division will be in a better position to conduct the broad program of research, to accumulate necessary data on water supplies, conduct training, and administer enforcement activities and construction grants under the Water Pollution Control Act of 1956. Gordon E. McCallum, who is chief of the Water Supply and Water Pollution Control Branch, will be in charge of the new division.

MEDICAL NEWS

ALABAMA

Surgical Meeting in Huntsville.—The International College of Surgeons, Alabama Surgical Section, will meet May 21-22 at the Russel Erskine Hotel, Huntsville. Four panel discussions are planned with the following titles and moderators:

Obstetrics, Dr. Julian Hardy, Birmingham.
Orthopedic Surgery (Whiplash Injuries), Dr. Paul Shannon, Birmingham.
Gynecology, Dr. Gilbert F. Douglas Sr., Birmingham.
Abdominal Surgery, Dr. Claude J. Hunt, Kansas City, Mo.

At the banquet, May 21, 7:30 p. m., Dr. E. V. Caldwell, Executive first vice-president of the Alabama Section, will preside, and guest speaker will be Senator Lister Hill. For information, write Dr. E. V. Caldwell, 2515 Memorial Parkway, Huntsville, Ala.

ALASKA

New Journal for Alaska Physicians.—The first issue of *Alaska Medicine* was published for March. The new publication was accepted as the official journal of the Alaska State Medical Association at its annual meeting March 20. The journal will be published quarterly, in March, June, September, and December. As explained in the first volume editorial, although Alaska has scarcely 100 practicing physicians "there is a pressing need for communication among physicians in Alaska." The first issue is being distributed free of charge to all physicians in the state and to all medical school libraries and state medical societies in the United States. Suggestions and contributions are invited. Proposed for future issues are a clinicopathological conference, a column devoted to news and current activities, review articles, a section devoted to the history of medicine in Alaska, and a "Letters to the Editor" column. Dr. William O. Maddock, 423 D St., Anchorage, is the editor of the journal, and Dr. William J. Mills Jr., is the editor-in-chief.

ARKANSAS

Dr. Krantz Goes to Kansas.—Dr. Kermit E. Krantz, assistant professor of obstetrics and gynecology, University of Arkansas Medical Center, Little Rock, resigned to become professor and chairman of the department of obstetrics and gynecology, University of Kansas Medical Center, Kansas City. His new appointment is effective July 1. Dr. Krantz is the first University of Arkansas man to receive the Markle Foundation award "given to young educators and researchers who show unusual promise in the field of medical science." In 1950, he joined the University of Vermont faculty, where he was promoted to assistant professor in obstetrics and gynecology.

COLORADO

Dr. Altemeier Gives Clagett Lecture.—Dr. William A. Altemeier, chairman, department of surgery, University of Cincinnati, delivered the annual Clagett Lecture at the University of Colorado Medical Center, Denver, April 10, on "Studies in Septic Shock."

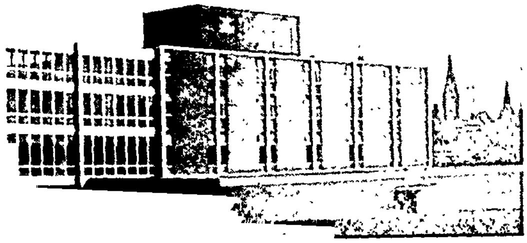
Establish Raymond R. Lanier Lectureship.—A lectureship in memory of the late Dr. Raymond R. Lanier of the faculty of the University of Colorado School of Medicine, Denver, was announced by Dean Robert J. Glaser. The first Lanier Lecture was given April 22 at the Medical Center by Dr. Louis H. Hempelmann, professor of experimental radiology, University of Rochester (N. Y.) School of Medicine, on "Malignant Disease in Irradiated Human Populations Exposed to Ionizing Radiation." Dr. Lanier was fatally injured last Nov. 24 near Holyoke when struck by a car during a hunting trip. He joined the university faculty in 1950 as head of the department of radiology, coming to Denver from the University of Chicago Clinics.

Nuclear Society Meeting.—On May 20 the Colorado Chapter of The Nuclear Society, a national organization of physicians, is holding its second annual regional meeting at the Denver Veterans Administration Hospital, sponsored by the University of Colorado. The meeting will occupy the entire day and will close with the annual dinner in the evening, when Col. Benjamin P. Blasingame, professor of astronautics at the Air Force Academy, will address the society on "Space Travel, Sense or Nonsense." The program will be presented by experts in nuclear medicine, recruited from the university, the Army, the Air Force, and from members of the local faculty of the Medical School and the V. A. staff. For information write Dr. Thad P. Sears, chief of Medical Service, Veterans Administration Hospital, 1055 Clermont St., Denver 20.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

DISTRICT OF COLUMBIA

Building Dedications Mark Convocation.—The Georgetown University Medical Center was highlighted in ceremonies of the university's Spring Convocation March 19. In a morning ceremony two new buildings were dedicated—the 3-million-dollar Lawrence C. Gorman Diagnostic and Research Building and the $1,227,000 Kober-Cogan Dormitory for medical and dental students. Construction was begun on the Gorman Building in September, 1957. Constructed of brick, aluminum, and glass, the edifice has four stories and a basement. It is a memorial to the late Lawrence C. Gorman, S.J., president of Georgetown University from 1942 to 1949, under whose administration the University Hospital was erected. Dentistry and Nursing, as well as medicine, will be provided for in the new building. The 375-seat auditorium will include a projection booth with several interpreters' booths. Some of the departments to be established in the building are physical medicine, radioisotope unit, obstetrics and gynecology, outpatient department, psychiatry, pediatrics, practical nursing, dentistry, hematology and pathology laboratories, urology research laboratory, and surgical research metabolic laboratory. The Kober-Cogan Dormitory for medical and dental students stands in the university's Medical Center Area, to the east of the new Gorman Diagnostic and Research Building. Air-conditioned throughout, the dormitory houses 200 students in double rooms, has six stories and a basement, and honors the memory of Dr. George M. Kober, dean of the Georgetown School of Medicine from 1900 to 1929, and Dr. William N. Cogan, first dean of the School of Dentistry. Other activities of the convocation included the conferring of honorary doctor of science degrees on Clemens V. Rault, D.D.S., dean of the School of Dentistry; Dr. Alfred Blalock, Johns Hopkins University surgeon; and Dr. Fred R. Sanderson; professor emeritus of surgery at Georgetown. President Sean T. O'Kelley, of the Republic of Ireland, was presented a citation, and the Gorman Building ceremonies were closed with an address, "The Challenge of Medical Education Today," by Dr. Hugh H. Hussey, dean of the School of Medicine.



The Laurence C. Gorman Diagnostic and Research Building, Georgetown University Medical Center, Washington, D. C.

FLORIDA

Plan Alumni Organization.—First steps toward formation of an alumni association of the University of Miami School of Medicine were taken at a meeting held at the school in Coral Gables April 6. Representatives of the three classes already graduated by the school, together with members of the class of 1959, voted to set up organizational machinery as quickly as possible. Dr. Arthur Radin was named chairman pro tem for the new association. A committee was appointed to work with him in drafting by-laws, outlining a program, and setting up a schedule for future meetings.

Society News.—The newly elected officers of the North Florida Radiological Society for 1959 are Dr. Marvin H. Johnson, Jacksonville, president, and Dr. Paul A. Mori, 800 Miami Road, Jacksonville, secretary. The North Florida Radiological Society is composed of radiologists from North Florida and South Georgia. Meetings are held quarterly in Jacksonville.——The election of new officers by the Greater Miami Radiological Society, held Jan. 21, was as follows: president, Dr. Richard D. Shapiro, Miami Beach; vice-president, Dr. Andre S. Capi, Hollywood; and secretary-treasurer, Dr. George P. Daurelle, Jackson Memorial Hospital, Miami. The meetings are held on the third Wednesday of each month at 8 p. m. at Jackson Memorial Hospital.

County Society Combats Tetanus.—Dade County Medical Association learned through the county health department that tetanus occurs seven times more frequently in Dade County than in the rest of the country and kills over half its victims. Association members had already conducted a successful poliomyelitis inoculation drive. To avoid misunderstandings and assure cooperation, Dade County sent each doctor a letter explaining why and when the antitetanus drive was to begin and suggesting he keep Friday afternoons and Saturday mornings free for vaccinating working people without appointments. A cardboard plaque was enclosed to post in the reception room as a reminder to patients. Doctors were urged to participate regardless of specialty. Next, a news release was sent to all papers with a fact sheet containing information on tetanus for background stories. Seven spot announcements were furnished to radio and TV stations. Six talks were given over radio and five TV shows arranged by the association's PR Committee. Announcements were displayed on post office bulletin boards and sent to 278 clubs throughout the county. Thirty-one thousand shots were given during the month-long campaign, according to Executive Secretary John Hanni.

ILLINOIS

Meeting of Anesthesiologists.—On May 17 the Illinois Society of Anesthesiologists will hold its annual meeting at the Sherman Hotel, Chicago. The morning will be devoted to a panel discussion, "Fluothane," moderated by Dr. Richard E. Lyons, Chicago, and including the following speakers: Drs. John Abajian, Burlington, Vt., Charles B. Pittinger, Iowa City, C. R. Stephen, Durham, N. C., and Harold L. Harris, Evanston. The afternoon speaker will be Dr. Henry K. Beecher, Boston, who will discuss "Pain." For information write Dr. Clifford A. Baldwin Jr., 522 Maple Ave., Wilmette, Secretary-Treasurer.

Organize Ileostomy Group.—Under the guidance of Dr. Joseph B. Kirsner, department of medicine of the University of Chicago, an organization known as the Ileoptomists of Chicago has been organized for the purpose of helping patients in the proper care and adjustment to their ileostomies. Meetings are held regularly on the last Monday of each month at 6:30 p. m. at the Fabric Salesman's Club, 222 W. Adams St. The organization has announced that they welcome new members and are eager to cooperate with all who may wish to avail themselves of the help provided by this group. Any patient with an ileostomy interested in joining the organization may contact the secretary, Mrs. Lee Vance of 330 Ridge Road, Barrington, Ill. (telephone: DU 1-1496). The president is Mr. Mat Martel. His address is 27 S. Elm. St., Northlake, Ill. (telephone: FI 3-9041). Physicians interested in attending meetings and in the general purpose of the Ileoptomists should contact Dr. Kirsner at MU 4-6100, Ext. 5563.

Chicago

Dr. Breinin to Give Memorial Lecture.—The Edward Lorenzo Holmes Memorial Lecture, "Contributions of Electromyography to Strabismus," will be given by Dr. Goodwin M. Breinin, professor of research ophthalmology, New York University–Bellevue Medical Center, New York City, the evening of May 18 at a joint meeting of the Chicago Ophthalmological Society and the Institute of Medicine of Chicago at the Palmer House.

Dr. Dawson Wins Surgical Prize.—The 1959 Chicago Surgical Prize for Surgical Research has been awarded to Dr. Donald Dawson, working at the University of Chicago, for his paper, "Plasma Sterilization—An Experimental and Clinical Study on Selective Destruction of Bacterial Nucleoproteins Without Plasma Denaturation." This year's prize check of $500 was donated by Dr. Edwin M. Miller. Dr. Dawson's paper was presented at the meeting of the Chicago Surgical Society May 1.

LOUISIANA

Dr. Farber Awarded Cancer Grant.—A grant creating another American Cancer Society professorship in cancer research was made to Tulane University School of Medicine, New Orleans, to support the lifetime cancer research of Dr. Emmanuel Farber. Dr. Farber has been working in pathology and biochemistry since 1947, when he received an American Cancer Society research fellowship at the University of California. Later he received a society research fellowship at Hektoen Institute for Medical Research in Chicago. From 1951 to 1955, he was an American Cancer Society scholar in research at Tulane. Dr. Farber's is the seventh lifetime cancer research professorship established by the society. In creating Dr. Farber's research professorship, the society established a $100,000 trust fund as a guarantee and will pay the scientist's annual salary out of funds raised each year until the trust and accrued interest are sufficient to pay the remaining years of the grant. In the event cancer is brought under control and the society disbands, the $100,000 trust fund goes to the institution for continued medical research. If for some reason, Dr. Farber is unable to carry on his research work, the trust fund reverts to the society.

MASSACHUSETTS

Annual Meeting in Boston.—The 178th anniversary meeting of the Massachusetts Medical Society will be held May 19-21 at the Statler Hilton Hotel, Boston, under the presidency of Dr. Charles C. Lund. Three films will be shown: "Cineradiography as a Routine Diagnostic Study," "Open Heart Surgery," and "Recognition and Management of Respiratory Acidosis." The annual discourse will be given by Dr. Henry F. Howe, Cohasset, on "Procedures in Consultation and Referral." A mock trial on "A Motor Vehicle Liability Case with Attendant Medical Problems for Trial Before a Jury" is planned for May 19, 3:30 p. m., with Dr. James F. Kenney, as chairman. The Shattuck Lecture will be given by Dr. Robert E. Gross on "Open Heart Surgery." Section meetings and luncheons are planned, and the following panel discussions and moderators are arranged:

The Selective Use of Whole Blood, Blood Components and the Complications of Transfusion Therapy, Dr. Mark F. Lesses, Boston.

Surgical Sepsis, Dr. Carl W. Walter, Boston.

Medical Fees for the Insured Patient, Dr. David W. Wallwork, North Andover.

Guest speaker at the annual banquet May 20, 7 p. m., will be Gen. Alfred M. Gruenther, president, American National Red Cross. Scientific exhibits are arranged. The annual golf tournament will be held May 19 and an exhibition of works of art by society members, May 21. For informaton write Dr. Robert W. Buck, 22 The Fenway, Boston, Secretary.

MICHIGAN

Dr. Ruedemann Honored.—For his "noteworthy contributions to ophthalmology," Dr. Albert D. Ruedemann, chairman, department of ophthalmology, Wayne State University College of Medicine, Detroit, received the Lucien Howe award from the University of Buffalo April 9. The Howe award is given annually "to an outstanding ophthalmologist." Dr. Ruedemann is director of Kresge Eye Institute and also heads the departments of ophthalmology at Detroit Receiving and Harper hospitals. He organized and headed the department of ophthalmology at Cleveland Clinic for 23 years.

MINNESOTA

Annual Meeting in Duluth.—The Minnesota State Medical Association will hold its annual meeting May 25-27 at the Hotel Duluth, Duluth. Panel discussions and moderators will include the following: "*What's New in Cardiovascular Disease*," Dr. F. J. Hirschboeck, Duluth, and "Management of Strokes," Dr. Ina A. Brown, St. Paul. Special lectures are scheduled as follows:

Russell D. Carman Memorial Lecture, "Breakthroughs in the Solution of the Stroke Problem," Dr. James E. Lofstrom, Detroit.

Minnesota Academy of Ophthalmology and Otolaryngology Lecture, "Use of Steroids in Ocular Disease," Dr. John E. Harris, Minneapolis.

Arthur H. Sanford Lecture in Clinical Pathology, "A Clinical and Pathological Comparison of Chronic Glomerulonephritis and Malignant Hypertension," Dr. Elexious T. Bell, Minneapolis.

Minnesota Medical Foundation Lecture, "Streptococcal Infections and Their Complications," Dr. Lewis W. Wannamaker, Minneapolis.

Northwestern Pediatric Society Lecture, "Nutritional Requirements of the Neonate," Dr. Theodore C. Panos, Little Rock, Ark.

Symposiums will be held on breast cancer, massive gastrointestinal bleeding, urological problems, and staphylococcus infections. Round-table luncheons and technical exhibits are planned. A gold tournament, skeet and trap events, and boat trips are arranged. The annual banquet ($6) will be held May 26, 7 p. m., with Dr. E. W. Ziebarth, dean, summer session, University of Minnesota, speaking on "Russia Today." For information, write Mr. Harold W. Brunn, 496 Lowry Medical Arts Building, St. Paul 2, Executive-Secretary.

MISSOURI

Open Division of Child Psychiatry.—Washington University's new William Greenleaf Eliot division of child psychiatry was opened officially at an open house at the former Mission Free School, 369 N. Taylor Ave., St. Louis, April 12. The new division, housed in the three-story Mission Free School Building, will be directed by Dr. E. James Anthony, Blanche F. Ittleson professor of child psychiatry at the university. The new division was named for Dr. Eliot, who founded the Mission Free School in 1840. He later was a founder of Washington University and its first chancellor. The Eliot division of child psychiatry will be composed of two units: the Child Evaluation Clinic, for diagnosis and treatment of mentally retarded children, and the Community Child Guidance Clinic, for emotionally disturbed children.

MONTANA

Dr. Harris Named Secretary-Treasurer.—At the 12th interim session of the Montana Medical Association, April 3-4, the House of Delegates elected Dr. William E. S. Harris, Livingston, to the office of secretary-treasurer to succeed the late Dr. T. R. Vye. Dr. Harris has served as assistant secretary-treasurer from September, 1957, until the death of Dr. Vye, when he became acting secretary-treasurer. Dr. Jesse T. Schwidde, 1231 N. 29th St., Billings, was elected assistant secretary-treasurer. Dr. Schwidde and Dr. Harris will hold office until the next regular election, held during the annual meeting in September.

NEW YORK

Foreign Lecturer.—Sir Howard W. Florey, professor of pathology, Sir William Dunn School of Pathology, University of Oxford, England, presented a lecture, "The Properties of Endothelium," April 24 at the University of Buffalo School of Medicine.

Personal.—On Feb. 5, Dr. Harold A. Abramson, chief of the psychobiology section, Biological Laboratory, Cold Spring Harbor, at the invitation and under the auspices of the National Research Council of Canada, gave a public lecture in Ottawa on "Explorations in the Chemistry of Mental Processes."—Dr. Joseph F. Rudman has been appointed Health Commissioner for the Clinton County Department of Health, effective Feb. 1.

Allergy Meeting.—The New York Allergy Society will hold a meeting May 20 at the Beekman Tower Hotel, First Avenue and 49th Street, New York City. The scientific session will be: "Studies on Gamma Globulins: Clinical Significance for the Allergist," by Dr. Paul A. M. Gross, research fellow in pediatrics, Harvard Medical School, research fellow in medicine, Children's Hospital, Boston. The scientific session at 8:30 p. m. is to be preceded by a dinner at 7:15. For information, write Dr. Sheppard Siegal, Secretary, The New York Allergy Society, 2 E. 84th St., New York 23.

Meeting of Surgical Section.—The International College of Surgeons, New York Surgical Section, will meet May 28-31 at the Concord Hotel, Kiamesha Lake, N. Y. The chairman of the scientific program committee is Dr. Henry P. Leis Jr. A motion picture program is planned and the scientific program will have the following panel titles:

Newer Concepts in the Surgical Treatment of Peptic Ulcer.
The Treatment of Thyroid Disease.
Therapy of Advanced Breast Cancer.
Problems in Obstetrics and Gynecology.
The Management of Patients with Multiple Injuries.
Problems in Proctology.
Reconstructive Surgery.
Therapy of Intractable Pain.
Cardiopulmonary Emergencies of Interest to the General Surgeon.
Bioatomic Medicine and Civil Defense.

New York City

Dr. Wechsler Honored.—The Hebrew University of Jerusalem honored Dr. Israel S. Wechsler by establishing the Israel Wechsler Chair of Neurology at the Hebrew University–Hadassah Medical School.

Annual Lecture.—The 25th annual Edwin A. Jarecki Memorial Lecture was delivered at the Northern Division of the Albert Einstein Medical Center April 29 by Dr. Ludwik Gross, chief, Cancer Research Unit, Veterans Administration Hospital, Bronx, and associate scientist, Sloan–Kettering Institute, Memorial Center. His topic was "Viral Etiology of Mouse Leukemia; Its Possible Implications for the Problem of Cancer in General."

Dr. Rawson Receives Goiter Award.—The American Goiter Association presented its "Long and Meritorious Service Award for those of its members who had contributed significantly to the scientific and business affairs of the Association" to Dr. Rulon W. Rawson, professor of medicine, Sloan–Kettering Division, Cornell University Medical College, May 1. Dr. Rawson has served on the council of the association, has been chairman of many of its committees, and was president in 1955-1956. He worked in the Thyroid Clinic of the Massachusetts General Hospital, Boston, and served on the faculty of Harvard University. He directs the Division of Clinical Investigation of the Sloan–Kettering Institute.

Summer Course on Pharmaceutical Librarianship.—The Columbia University School of Library Service announced that during the 1959 summer session a special course on Pharmaceutical Literature and Librarianship will again be offered. The instructor will be Miss Winifred Sewell, librarian, Squibb Institute, New Brunswick, N. J. The course will provide a survey and evaluation of library materials in the field of pharmacy. Designed as advanced training for professional librarians now in service, the course has been scheduled to meet two hours daily from Monday through Friday for the first three weeks of the Summer Session, July 6-24, 7-8:40 p. m. Classes will meet at the College of Physicians and Surgeons at the Columbia University Medical Center. The fee for the course is $111, plus a registration fee of $10. Admission requires a bachelor's degree. Applications for admission, and information about related courses may be obtained from the School of Library Service, Columbia University, New York 27.

OREGON

Goiter Essay Award to Researcher.—The Van Meter prize of the American Goiter Association ($300), for the best work on the subject of goiter was awarded to Dr. Takashi Yamada for his "Studies on the Mechanism of Hypothalamic Control of Thyrotropin Secretion in the Rat." Dr. Takashi Yamada, a native of Japan, has M.D. and Ph.D. degrees from Gunma University. Since September, 1957, he has been a research fellow in the Division of Endocrinology at the University of Oregon Medical School, Portland, where he works under the direction of Dr. Monte A. Greer.

PENNSYLVANIA

Philadelphia

Annual Hospital Banquet.—The annual banquet of the Ex-Interne and Resident Association of the Hospital of the University of Pennsylvania will be held on Friday, June 12, at the Warwick Hotel, Philadelphia, beginning at 6 p. m. For information, write Dr. John W. Greene Jr., 104-6 Dulles Building, University Hospital, 3400 Spruce St., Philadelphia 4, Secretary.

Neurosurgical Meeting.—The first meeting of the newly organized Philadelphia Neurosurgical Society was held at the Jefferson Medical College May 15. Active members in this organization include all neurological surgeons from the State of Pennsylvania. Invited guests for this meeting were present from the District of Columbia, Maryland, Delaware, and New Jersey. Counselors and organizers of the society are Drs. Robert A. Groff, J. Rudolph Jaeger, Axel K. Olsen, and Michael Scott. Elected to officiate at this first meeting were president, Dr. Francis C. Grant; vice-president, Dr. Temple S. Fay; and secretary-treasurer, Dr. Frederick Murtagh.

Dr. Koelle to Head Pharmacology Department.—Dr. George B. Koelle, dean of the University of Pennsylvania Graduate School of Medicine, and chairman of the department of physiology and pharmacology of the Graduate School of Medicine, was elected chairman of the department of pharmacology of the university's School of Medicine, effective July 1. Dr. Koelle will succeed Dr. Carl F. Schmidt, who will retire from his departmental administrative duties after 28 years as professor and chairman. He will continue temporarily to serve

Cl. No. 2327
Date of Acc.

as dean of the Graduate School of Medicine and will retain responsibility for teaching of pharmacology there while in his new Medical School position.

TENNESSEE

Dr. Rogers Receives Pathology Award.—Dr. Stanfield Rogers, director of Memorial Research Center, University of Tennessee, Knoxville, received the third annual award of the American Society for Experimental Pathology and a $1,000 honorarium contributed by Parke–Davis Co. in "recognition of his basic research on how tumors and cancers behave and grow." Dr. Rogers previously was professor of pathology at Duke University, assuming his present position early last year. He won the award for research done at Duke and the Rockefeller Institute for Medical Research, New York City.

WISCONSIN

Alumni Dinner in Atlantic City.—The University of Wisconsin Medical Alumni dinner will be held June 10, 6 p. m., in the Crystal Dining Room of the Sheraton–Ritz Hotel, Atlantic City. Since the alumni association is in the formative stages, all alumni are urged to attend.

GENERAL

Dr. Bishop Named World Medical Association Officer.—Dr. John M. Bishop, Bellevue, Wash., has been named deputy secretary-general of the World Medical Association. Dr. Bishop will assist Dr. Louis Bauer, World Medical Association secretary-general. Dr. J. Renaud Lemieux, Quebec, Canada, has been elected to fill a casual vacancy as president-elect.

Meeting on Mental Deficiency.—The American Association on Mental Deficiency will hold its 83rd annual meeting at the Hotel Schroeder, Milwaukee, May 19-23, under the presidency of Dr. George Tarjan. A symposium "Status of the A. A. M. D. Project—Past, Present and Future" will be held the morning of May 20. Section meetings will be held under the following titles: administration, education, medicine, social work, psychology, and rehabilitation. A joint education and psychology symposium is planned for the morning of May 22. Tours will be conducted the afternoon of May 21. A joint session with Wisconsin's ninth annual Institute on the Slow Learner is planned. Registration fee is $1 for members and $2 for nonmembers. Exhibits are scheduled.

History of Medicine Meeting in Cleveland.—The 32nd annual meeting of the American Association for the History of Medicine will be held May 21-23 in Cleveland with headquarters at the Cleveland Medical Library. A symposium on the heart will be moderated by Dr. Chauncey D. Leake, President, Ohio Academy of Medical History, May 22. The Garrison Lecture, "A View of Nineteenth Century Medical Historiography in the U. S. A.," will be given by Walton B. McDaniel II, Philadelphia. At the annual dinner, May 22, 7:30 p. m., with Dr. Owsei Temkin, Baltimore, president of the association, presiding. Dr. Saul Jarcho, New York City, will give "Hoaxes in Medical Literature." A roundtable discussion commemorating the centenary of Charles Darwin's "Origin of Species" will be moderated by Dr. Bruno Gebhard the morning of May 23. For information, write Dr. John B. Blake, c/o Smithsonian Institution, Washington 25, D. C.

Meeting of Gynecologists.—The American Gynecological Society will hold its 82nd annual session May 21-23 at The Homestead, Hot Springs, Va. The presidential address will be given at noon, May 22, by Dr. Lewis C. Scheffey, Philadelphia. Of the 14 papers scheduled for presentation, the following include invited authors:

Rupture of the Marginal Sinus and Abruption: Some Relationships, Dr. James H. Ferguson and Dr. Robert L. Hatton, Miami, Fla.
Demonstration of Trophoblast in the Circulating Blood During Pregnancy, Dr. Gordon W. Douglas, New York City.
The Relationship of the Squamo-Columnar Junction and the Endocervical Glands to the Site of Origin of Carcinoma of the Cervix, Dr. W. Norman Thornton Jr., Charlottesville, Va.
Radical Vulvectomy with Inguinal, Femoral and Iliac Node Dissection, Dr. Howard Ulfelder, Boston.

The annual dinner will be held the evening of May 22. For information, write Dr. Andrew A. Marchetti, Georgetown Hospital, Washington 7, D. C., Secretary.

Telecast on Hypertension.—A symposium on hypertension will be televised from the Cleveland Clinic on May 27 to 25 closed-circuit locations throughout the country at 9 p. m. EDT that evening. Physicians are invited to be present. The following will participate: Drs. Harriet P. Dustan, Cleveland Clinic; Edward D. Freis, Georgetown University School of Medicine; Irvine H. Page, Cleveland Clinic; Samuel Proger (moderator), Tufts University School of Medicine; Robert W. Wilkins, Boston University School of Medicine. They will consider the problems of several patients who will be presented to them. The problems will illustrate practical aspects of hypertension which the physician is likely to encounter in his day to day practice. This program is sponsored by the CIBA Pharmaceutical Products, Inc., under the title "CIBA TV Clinical Symposia." Cities where the symposium will be televised include: Albany, Atlanta, Baltimore, Boston, Brooklyn, Chicago, Cleveland, Denver, Detroit, Garden City, Kansas City, Los Angeles, Memphis, Miami, Newark, New York, Philadelphia, Pittsburgh, Portland, St. Louis, Salt Lake City, San Francisco, Seattle, Syracuse, and Washington, D. C. For information, write the Medical Radio and Television Institute, 130 E. 59th St., New York 22.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

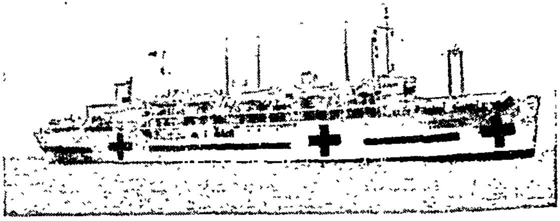
Hospital Ship for Overseas Health Aid.—Project HOPE is the principal activity carried out by the People-to-People Health Foundation, Inc., and involves chartering the fully equipped Navy hospital ship, Consolation, and using it as a privately supported, privately operated medical and medical training center in friendly nations overseas. The HOPE Project (HOPE stands for Health Opportunity for People Everywhere) will depend on donations from individuals, corporations, and foundations. The American Medical Association and several drug manufacturers have made contributions in advance of any public request for funds in order to get the project organized. In addition, the drug manufacturers have indicated that they will supply the drug needs of the project. President Eisenhower announced that the Navy will release the ship for charter as soon as financial arrangements for operations are completed. The scheduled sailing date is Sept. 15, from San Francisco. During the first year of operation, the ship will visit countries in Southeast Asia. It will be operated for the foundation by the American President Lines at cost to them and without any fee. The HOPE project will go where it is invited by the medical profession of a country. The Consolation has about 800 beds but will be used primarily for teaching. A permanent party of 20 doctors, including two dentists, and 15 nurses in addition to required technical personnel is planned. The People-to-People Health Foundation, Inc., is a private, independent nonprofit corporation originally sponsored by President Eisenhower. Its program is organized of 41 different committees of private citizens with the objective of including as many phases of our life and culture as would be meaningful. There are committees in fine arts, sports, and the medical and health professions. The committees have taken action to incorporate to give permanency to their work and tax-deductible status to the gifts they receive. Dr. William B. Walsh is the president of Project HOPE, and the address of the project is P. O. Box 9808, Washingto 15, D. C.



The USS Consolation (Official United States Navy Photograph).

CORRECTION

Meeting on Sterility in Atlantic City.—Under this title in Medical News in THE JOURNAL, March 28, page 1494, the item should have stated that Dr. Edward C. Reifenstein Jr., New Brunswick, N. J. (listed as 1959 president), was chairman of the program committee with Dr. Sheldon Payne, Los Angeles, as 1959 president; the presidential address (given as "Nolle Nodere") should have been "Nolle Nocere"; and the Simmons Memorial addressee (given as Dr. Alan N. B. Grant) should read Dr. Alan Grant, Sydney, Australia.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing applications is June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written*. Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Reciprocity*. Phoenix, July 15-17. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity*. Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

California: *Written*. San Francisco, June 15-18; Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral*. San Francisco, Juune 13; Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical*. San Francisco, June 14; Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Colorado:* *Examination*. Denver, June 9-10. *Reciprocity*. Denver, July 14. Sec., Dr. John B. Farley, 712 Republic Bldg., Denver 2.

Connecticut:* *Homeopathic Board. Reciprocity*. Derby, June 9. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby. *Regular Board. Examination*. Hartford, July 14-16. Sec., Dr. Staley B. Weld, 160 St. Ronan St., New Haven.

Delaware: *Examination*. Dover, July 14-16. *Endorsement*. Dover, July 23. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:* *Written*. Washington, June 8-9. Final date for filing application is May 1. Sec., Dr. Daniel Leo Finucane, 1740 Massachusetts Ave., N. W., Washington.

Florida:* *Examination*. Miami Beach, June 21-23. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity*. Atlanta, June 10-11. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call*. Act. Sec., Dr. F. L. Conklin, Agana.

Hawaii: *Written*. Honolulu, July 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: *Examination and Endorsement*. Boise, July 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination*. Chicago, July 7-10. *Reciprocity*. Chicago, July 10. Supt. of Registration, Mr. Frederic B. Selcke, Capitol Building, Springfield.

*Basic Science Certificate required.

DEATHS

Akers, Waller C. Ⓜ Stuart, Va.; University College of Medicine, Richmond, 1912; served as president of the Patrick County Medical Society; formerly mayor of the town of Stuart; president of the Patrick County Bank; past-president of the Stuart Rotary Club, of which he was a charter member; served on the medical examiners board during World War I and was awarded a selective service medal for his medical service during World War II; owner of the Stuart Hospital; died Feb. 27, aged 75.

Alford, Warren Grady Ⓜ Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1914; served in France during World War I; died in the Kennedy General Hospital March 1, aged 69.

Allen, Charles F., Middleton, Wis.; Milwaukee Medical College, 1900; served two terms as village president; since 1915 president of the Bank of Middleton; died in St. Mary's Hospital, Madison, Feb. 17, aged 85.

Anderson, Joel Ⓜ North Platte, Neb.; John A. Creighton Medical College, Omaha, 1915; served as county physician and member of the city council; past-president of the Kiwanis Club; on the staff of the St. Mary and North Platte Memorial hospitals; died Feb. 18, aged 74.

Archambault, Joseph Arthur, Fall River, Mass.; School of Medicine and Surgery of Montreal, Que., Canada, 1901; died in Notre Dame de l'Esperance Hospital, Montreal, Que., Feb. 2, aged 83.

Barrett, Gilbert Michael Ⓜ San Francisco; born in Elizabeth, Ill., in 1869; Bellevue Hospital Medical College, New York City, 1895; fellow of the American College of Surgeons; veteran of World War I; in 1918 became chief surgeon for the shipbuilding division of Bethlehem Steel Company and was with them in this capacity until 1954; medical director for the San Francisco District, General Electric Company, for the period from 1917 to 1956; associated with St. Francis Memorial Hospital and the St. Luke's Hospital, where in December, 1956, he was honored and placed on the emeritus staff; died in St. Luke's Hospital Jan. 10, aged 89.

Beckary, Albert M. Ⓜ Indian Lake, N. Y.; Cornell University Medical College, New York City, 1905; died Jan. 21, aged 81.

Berry, John William Ⓜ Albuquerque, N. M.; University of Colorado School of Medicine, Denver, 1939; veteran of World War II; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Trudeau Society; at one time on the faculty of his alma mater; chief of chest service, Veterans Administration Hospital; associate editor, section on pulmonary diseases, "Cyclopedia of Medicine, Surgery, and the Specialties"; died Feb. 23, aged 44.

Blechman, Abram Joel Ⓜ Baltimore; Medical College of Virginia, Richmond, 1926; member of the American Academy of General Practice; associated with the Sinai Hospital; died Nov. 8, aged 58.

Blickenstaff, Augustus J. Ⓜ Peoria, Ill.; State College of Physicians and Surgeons, Indianapolis, 1907; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of the Proctor Hospital; died in St. Petersburg, Fla., Feb. 11, aged 86.

Bousfield, Cyril Eustace, Woolwich, Maine; Pennsylvania Medical School (Medical Department of St. John's University) Shanghai, China, 1931; served as a medical missionary in China; died March 1, aged 88.

Bower, Lester Edward Ⓜ Chicago; Northwestern University Medical School, Chicago, 1914; clinical assistant professor emeritus of pediatrics at the University of Illinois College of Medicine; specialist certified by the American Board of Pediatrics; past-president of the staffs of the Illinois Masonic and Martha Washington hospitals; served on the staffs of the Cook County and Lutheran Deaconess hospitals; died in the Alexian Brothers Hospital March 3, aged 70.

Bowman, William Frederick, Canton, Mo.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1900; veteran of World War I; died Feb. 8, aged 89.

Boyd, Clarence Elbert Ⓜ Lakeland, Fla.; Hospital College of Medicine, Louisville, 1902; veteran of World War I; died in the Morrell Hospital Feb. 2, aged 79.

Boyle, Jeremiah Joseph, Cambridge, Mass.; Harvard Medical School, Boston, 1905; died in the Cambridge City Hospital Feb. 11, aged 81.

Britton, Harry Albert Ⓜ Ithaca, N. Y.; Medico-Chirurgical College of Philadelphia, 1913; served on the faculty of Cornell University; died in the Tompkins County Hospital Feb. 17, aged 77.

Ⓜ Indicates Member of the American Medical Association.

Brown, Greenberry Bedford Ⓜ Georgetown, Ky.; Johns Hopkins University School of Medicine, Baltimore, 1917; veteran of World War I; honorary member of staffs of St. Joseph's and Good Samaritan hospitals in Lexington, and the John Graves Ford Memorial Hospital; died in St. Louis Feb. 18, aged 66.

Brown, Wayne Ebert Ⓜ Clyde, Ohio; Western Reserve University School of Medicine, Cleveland, 1932; veteran of World War II; served as county coroner; on the staff of the Bellevue (Ohio) Hospital, where he died Feb. 20, aged 53.

Burgeson, Samuel D. Jr., Los Angeles; College of Medical Evangelists, Loma Linda and Los Angeles, 1929; at one time police and fire department surgeon; on the staff of the Lincoln Hospital; died Feb. 24, aged 58.

Chaimson, Harry, Boston; St. Louis College of Physicians and Surgeons, 1921; died in Milton, Mass., Jan. 4, aged 66.

Clements, William R., Woodbury, N. J.; Medical College of Virginia, Richmond, 1894; died in Trenton Dec. 31, aged 86.

Coffee, Percy Elmos, Davenport, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1903; president and founder of the Elmo Company; died in St. Luke's Hospital Feb. 6, aged 77.

Collins, Thomas F. Ⓜ Adamsville, Pa.; Eclectic Medical Institute, Cincinnati, 1904; died in the Meadville (Pa.) City Hospital Feb. 13, aged 80.

Combes, Abbott Carson Jr., Sheffield, Mass.; Columbia University College of Physicians and Surgeons, New York City, 1911; veteran of World War I; served as a member of his local draft board for the duration of World War II, and also as examining physician, New York City; division surgeon for the Long Island Railroad; on the staff of the Flushing (N. Y.) Hospital; at one time president of the Combes' Sanitarium in Corona; died in the Charlotte Hungerford Hospital, Torrington, Conn., Feb. 27, aged 74.

Dickson, George LeGrande, Manning, S. C.; Medical College of South Carolina, Charleston, 1895; also a druggist; died in the Clarendon Memorial Hospital Feb. 19, aged 90.

Dorr, Addison Michael, Wauwatosa, Wis.; Northwestern University Medical School, Chicago, 1912; past-president of the Milwaukee Roentgen Ray Society; served on the staffs of the Veterans Administration Center in Wood, Evangelical Deaconess Hospital in Milwaukee, St. Joseph's Hospital, Beaver Dam, and St. Mary's Hospital in Columbus; died in St. Joseph's Hospital in Milwaukee Feb. 24, aged 72.

Douglas, Edmund Turner Ⓜ Hillsboro, Ill.; St. Louis University School of Medicine, 1912; on the staff of Hillsboro Hospital; president of the Montgomery County National Bank; died in St. Luke's Hospital, St. Louis, Feb. 9, aged 69.

Dowd, Thomas Francis Ⓜ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1935; past-president of the Philadelphia Academy of General Practice; on the staff of the St. Mary's Hospital, Nazareth, and St. Joseph's hospitals; director of the Pennsylvania Blue Shield; veteran of World War II; team physician for the Philadelphia Eagles of the National Football League; in 1939-1940 team physician for the Chicago Cubs; died Feb. 23, aged 53.

Drummond, Alvin Cash Ⓜ New York City; born in Grant, Mich., Feb. 27, 1903; Columbia University College of Physicians and Surgeons, New York City, 1932; specialist certified by the American Board of Urology; certified by the National Board of Medical Examiners; member of the American Urological Association; fellow of the American College of Surgeons, American Academy of Compensation Medicine, International College of Surgeons, and the American Geriatrics Society; member of the New York Academy of Medicine; assistant clinical professor of urology, New York University College of Medicine; associated with University Hospital (New York University–Bellevue Medical Center), Gouverneur Hospital, and Doctors Hospital, where he died Dec. 22, aged 55.

Fenton, Kevin Joseph Ⓜ Lieut., U. S. Navy, Akron, Ohio; Western Reserve University School of Medicine, Cleveland, 1956; interned at the Children's Medical Center in Boston; stationed at the U. S. Naval Radiological Defense Laboratory in San Francisco; died in San Francisco Feb. 26, aged 28.

Fibush, Arthur, Oakland, Calif.; Oakland College of Medicine and Surgery, 1916; from 1920 to 1925 health officer of the city of Piedmont; during World War II served as a medical examiner for an induction board; died in the Samuel Merritt Hospital, Feb. 22, aged 68.

Flesche, Bernard Alton Ⓜ Lake City, Minn.; born in Walnut Grove, July 17, 1904; University of Minnesota Medical School, Minneapolis, 1934; member of the American Academy of General Practice; past-president and secretary-treasurer of the Wabasha County Medical Society; past-president of the Southeastern Minnesota Academy of General Practice; from 1956 to 1958 member of the executive board of the Minnesota Academy of General Practice and in 1954 received its award for "Top Flight General Practitioner"; member of the Minnesota Public Health Conference, World Health Organization, Association of Military Surgeons of the United States, Minnesota Medical Foundation, and Phi Rho Sigma fraternity; past-president of Lake City Chamber of Commerce; treasurer of the Wabasha County Historical Society; veteran of World War II; a veteran Boy Scout leader and received the Silver Beaver Award for "long and distinguished service to boyhood" in 1954; died in St. Mary's Hospital, Rochester, Minn., Feb. 12, aged 54.

Floyd, George Matthew Ⓜ Hawthorne, Fla.; Atlanta College of Physicians and Surgeons, 1909; died in the Alachua General Hospital, Gainesville, Feb. 17, aged 77.

Fraley, Hugh B., Ashland, Ky.; Louisville (Ky.) Medical College, 1895; died Feb. 20, aged 93.

Friday, Clarence Claude Bausella Ⓜ Seguin, Texas; Howard University College of Medicine, Washington, D. C., 1926; served as president twice and as secretary for 23 years for the Southwest Texas District Medical, Dental, and Pharmaceutical Association, which presented him a plaque for "25 years of faithful and distinguished service"; formerly president and executive secretary of the Lone Star State Medical Association; on the staff of the Seguin Hospital; died Dec. 26, aged 62.

Gethner, Max Peter Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1911; specialist certified by the American Board of Internal Medicine; served on the faculty of Rush Medical College; associated with Lutheran Deaconess Home and Hospital, Norwegian American Hospital, Walther Memorial Hospital, and Columbus Hospital; staff physician for the International Ladies Garment Workers Union; on the courtesy staff of Michael Reese Hospital, where he died March 4, aged 71.

Glanville, William Earl, Southampton, N. Y.; Cornell University Medical College, New York City, 1911; served in the U. S. Public Health Service and the U. S. Navy; attending physician for the public schools; for many years on the staff of the Southampton Hospital, where he died Jan. 13, aged 70.

Green, Lafayette, East St. Louis, Ill.; St. Louis College of Physicians and Surgeons, 1910; chief deputy St. Clair County coroner from 1920 to 1928; died in Washington Park Jan. 22, aged 70.

Harris, Claib Bosworth Ⓜ Garnett, Kan.; University Medical College of Kansas City, Mo., 1906; served as county health officer, county coroner, and for a time as city health officer in Garnett; associated with the Anderson County Hospital in Garnett and the Trinity Lutheran Hospital in Kansas City, Mo., where he died Feb. 4, aged 82.

Hart, James Finlay, New York City; Syracuse University College of Medicine, 1911; past-president of the Bronx County Medical Society and the New York Diabetes Association; a life member of the New York Academy of Medicine; served as adjunct professor of medicine at the New York Polyclinic Medical School and Hospital and associate clincal professor of medicine at the New York Medical College, Flower and Fifth Avenue Hospitals; associated with the Midtown Hospital; died in the New York Polyclinic Medical School and Hospital Feb. 24, aged 73.

Hopkins, Frank Ⓜ Hot Springs, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; died Feb. 28, aged 86.

Hudnall, Harry Gilman Ⓜ Roanoke, Va.; University of Virginia Department of Medicine, Charlottesville, 1931; veteran of World War II; associated with the Veterans Administration Hospital; past-president of the Alleghany, Bath Counties Medical Society; died in the Jefferson Hospital Feb. 20, aged 52.

Lemus, Leopoldo, San Antonio, Texas; Escuela Médico Militar, México, D. F., 1923; died in St. Benedict Hospital Feb. 9, aged 60.

Leonard, Edwin Jr., North Bergen, N. J.; Harvard Medical School, Boston, 1898; died in the Christ Hospital, Jersey City, Dec. 11, aged 87.

Llewellyn, John Rees, Salt Lake City, Utah; Rush Medical College, Chicago, 1916; served as a member of the city board of health; during World War II served on the draft appeal board; associated with the Latter Day Saints Hospital; died Feb. 7, aged 72.

Lyman, Alexander Victor, New York City; Columbia University College of Physicians and Surgeons, New York City, 1926; certified by the National Board of Medical Examiners; served overseas during World War I; on the staff of the Roosevelt Hospital; died Feb. 27, aged 62.

McCarthy, Edwin Eugene Ⓜ Sarasota, Fla.; Syracuse University College of Medicine, 1937; formerly practiced in Auburn, N. Y., where he was on the staffs of the Mercy and Auburn Memorial hospitals, and the Auburn State Prison; died Feb. 16, aged 47.

McFaddin, James Thomas Ⓜ Johnson City, Tenn.; Loyola University School of Medicine, Chicago, 1916; member of the American Society of Anesthesiologists and the American Academy of General Practice; served as city commissioner and city physician and was deputy coroner of Washington County; on the staff of the Memorial Hospital; died Feb. 3, aged 66.

McNary, Wilbert Francis Ⓜ East St. Louis, Ill.; Barnes Medical College, St. Louis, 1909; past-president of the St. Clair County Medical Society; veteran of World War I; on the staff of St. Mary's Hospital, where he died Feb. 1, aged 77.

Mann, Henry L., Holliston, Mass.; Boston University School of Medicine, 1903; served during World War I; assistant medical director for the Equitable Life Assurance Society of America; died in the Framingham (Mass.) Union Hospital Feb. 15, aged 81.

Martinez-Carranza, Enrique, Brownsville, Texas; Loyola University School of Medicine, Chicago, 1917; died in Monterrey, M. L., Mexico, Dec. 4, aged 66.

Mathews, Robert William Ⓜ Greensboro, N. C.; Emory University School of Medicine, Atlanta, 1932; associated with the Moses H. Cone Memorial Hospital and the Wesley Long Community Hospital; died Feb. 6, aged 50.

Mead, Chester Ira Ⓜ Bakersfield, Calif.; State University of Iowa College of Medicine, Iowa City, 1931; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; past-president of the Kern County Medical Society; on the staff of the Mercy Hospital; past-president of the Bakersfield Rotary Club; died Feb. 11, aged 58.

Middleton, Daniel Spencer Ⓜ Rising Fawn, Ga.; Medical Department of Grant University, Chattanooga, Tenn., 1894; physician for the Alabama Great Southern Railway; served in both the Georgia House and Senate; died Feb. 8, aged 88.

Miller, Benjamin Ⓜ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1924; member of the American Academy of General Practice; died Dec. 24, aged 58.

Miller, Nora Rice, Denver; University of Colorado School of Medicine, Denver, 1908; died Feb. 9, aged 90.

Muncie, Henry L. Ⓜ Brazil, Ind.; Medical College of Indiana, Indianapolis, 1905; died Feb. 14, aged 79.

Muniz, Rafael Rufino Ⓜ New York City; Medical College of Virginia, Richmond, 1932; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; on the staff of the University Hospital; died Dec. 1, aged, 55.

Nattrass, Robert B., Bloomfield, W. Va., New York Homeopathic Medical College and Hospital, New York City, 1905; died Feb. 3, aged 76.

Nelson, Aaron Archer, Allendale, N. J.; University and Bellevue Hospital Medical College, New York City, 1899; veteran of World War I; formerly on the staff of St. Francis Hospital in Jersey City; died in the Valley Hospital, Ridgewood, Feb. 1, aged 80.

Newell, John Oliver, Franklinton, N. C.; College of Physicians and Surgeons, Baltimore, 1910; past-president of the Franklin County Medical Society; died Feb. 18, aged 82.

Nova, Jules Mark Ⓜ Freeport, N. Y.; Long Island College Hospital, Brooklyn, 1902; specialist certified by the American Board of Ophthalmology; on the staff of the Brooklyn Eye and Ear Hospital; died in the Nassau Hospital in Mineola Dec. 12, aged 79.

Orlick, Abraham P., Miami Beach, Fla.; Long Island College Hospital, Brooklyn, 1922; formerly practiced in Brooklyn, where he was on the staffs of the Unity, Crown Heights, and Brooklyn Women's hospitals; died in the Miami Heart Institute Feb. 13, aged 70.

Peberdy, Wilfred Montague Ⓜ Captain, U. S. Navy, retired, Orange, Conn.; Yale University School of Medicine, New Haven, 1917; entered the U. S. Navy in 1917 and retired Dec. 1, 1946; veteran of World Wars I and II; died in the Veterans Administration Hospital in West Haven Feb. 13, aged 67.

Piggott, John Burr Ⓜ Washington, D. C.; University of Maryland School of Medicine, Baltimore, 1907; veteran of World War I; associated with the Eastern Dispensary and Casualty Hospital and the Central Dispensary and Emergency Hospital; at one time on the teaching staff of the George Washington University School of Medicine; died in Florence, S. C., Feb. 10, aged 82.

Rawleigh, George Nelson, Paducah, Ky., St. Louis University School of Medicine, 1924; also a graduate in pharmacy; died in the Western Baptist Hospital Feb. 13, aged 68.

Rice, Ollie Walker Ⓜ McAlester, Okla.; Rush Medical College, Chicago, 1897; served as city councilman and school board member; surgeon for the Rock Island Railroad; on the staffs of the McAlester General Hospital and St. Mary's Hospital, where he died Feb. 3, aged 87.

Ross, Samuel Herman Ⓜ Waco, Texas; Wayne University College of Medicine, 1935; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; veteran of World War II; associated with the Veterans Administration Center; died Feb. 13, aged 52.

Rothwell, John Joseph, Flushing, N. Y.; Bellevue Hospital Medical College, New York City, 1893; formerly on the staffs of the New York Foundling and Bellevue hospitals in New York City; died Feb. 15, aged 87.

Scheffel, Alfred Garland Ⓜ Beverly Hills, Calif.; Northwestern University Medical School, Chicago, 1937; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the International College of Surgeons and the American College of Surgeons; veteran of World War II; instructor in surgery (orthopedic) at the University of Southern California School of Medicine; on the staffs of the California Babies' and Children's Hospital, Los Angeles County Hospital, and the California Hospital; formerly orthopedic surgeon for the police and fire departments; died in Santa Monica (Calif.) Hospital Feb. 13, aged 45.

Schwer, Carl Ⓜ Calhan, Colo.; Kansas City (Mo.) University of Physicians and Surgeons, 1927; recently appointed county physician; died Feb. 16, aged 75.

Shattuck, Martha Isabel Boger Ⓜ New Castle, N. H.; Boston University School of Medicine, 1915; veteran of World War I; on the staff of the Portsmouth (N. H.) Hospital; died Feb. 7, aged 66.

Sheaffer, Clinton Paul Ⓜ Haddonfield, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1919; died Dec. 7, aged 66.

Shelton, Samuel Wayne Ⓜ Tuscaloosa, Ala.; University of Arkansas School of Medicine, Little Rock, 1928; member of the American Psychiatric Association; veteran of World War II; formerly health officer of Winston County; served on the staff of the Hastings (Neb.) State Hospital; on the staff of the Veterans Administration Hospital; died in the University Hospital, Birmingham, Feb. 8, aged 54.

Stewart, Chauncey Calvin Ⓜ Youngstown, Ohio; University of Wooster Medical Department, Cleveland, 1907; on the honorary staff of the Youngstown Hospital Association; died in the North Side Unit of the Youngstown Hospital Feb. 15, aged 81.

Stoney, George Franklin Ⓜ Erie, Pa.; Jefferson Medical College of Philadelphia, 1910; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; member of The Endocrine Society; fellow of the American College of Physicians; past-president of the Erie County Medical Society; associated with the Erie County Tuberculosis Hospital, Hamot Hospital, and St. Vincent's Hospital; died in the Hamot Hospital Feb. 1, aged 72.

Sullivan, Michael H. Ⓜ Newport, R. I.; born in 1877; Harvard Medical School, Boston, 1900; for many years a member of the board of health, of which he served as vice-president and president; past-president of the Rhode Island Medical Society; in 1953 was cited by the society as the "Practitioner of the Year"; lauded by the General Assembly and the city council of his own city; in 1955 the Newport School Committee named its new elementary school after him; Newport Hospital, where he served as chief obstetrician for many years and as chief of the medical staff, dedicated a special bronze plaque to him in 1953, and in the same year he was the recipient of an honorary doctor of science degree from the Rhode Island College of Pharmacy and Allied Sciences; president of the Aquidneck Realty Company and director of the Newport Oil Company; died in the Newport Hospital Feb. 19, aged 81.

Sycamore, Leland Schofield Ⓜ Ogden, Utah; University of Tennessee College of Medicine, Memphis, 1943; veteran of World War II; on the staff of St. Benedict Hospital and Dee Hospital, where he died Feb. 17, aged 44.

Tatum, William Edgar Ⓜ *Gatesville*, Texas; Memphis (Tenn.) Hospital Medical College, 1899; died Feb. 3, aged 85.

Thornbury, Richard Henry Ⓜ North Collins, N. Y.; University of Michigan Medical School, Ann Arbor, 1924; affiliated with the Bertrand Chaffee Hospital in Springville, and Our Lady of Victory Hospital in Lackawanna; member of the board of directors of the Tri-County Memorial Hospital in Gowanda, where he was on the staff; school physician; died Jan. 7, aged 59.

Vinyard, George Thomas Ⓜ Amarillo, Texas; Barnes Medical College, St. Louis, 1894; twice president of the Potter County Medical Society; served as president of the Panhandle District Medical Society; formerly served on the city board of health and as city health officer; fellow of the American College of Surgeons; on the staffs of the Northwest Texas Hospital and St. Anthony's Hospital; died in the Underwood Clinic Hospital Feb. 11, aged 89.

Watson, Wilfred Murray Ⓜ Northboro, Mass.; Tufts College Medical School, Boston, 1937; member of the American Academy of General Practice; veteran of World War II; member of the medical staff of the Marlborough Hospital in Marlboro, where he died Feb. 12, aged 46.

Wegmann, Norbert John Ⓜ Milwaukee; Marquette University School of Medicine, Milwaukee, 1927; fellow of the American College of Surgeons; member of the Industrial Medical Association; past-president of the Medical Society of Milwaukee County; served on the faculty of his alma mater; associated with Misericordia and Deaconess hospitals; died in Fort Lauderdale, Fla., Feb. 2, aged 58.

Woodward, Clayton E. Ⓜ Decatur, Ill.; Northwestern University Medical School, Chicago, 1906; past-president of the Macon County Tuberculosis and Visiting Nurses Association; on the Selective Service Examining boards during World Wars I and II; member and past-president of the staff of Decatur and Macon County Hospital; affiliated with St. Mary's Hospital; died Feb. 13, aged 75.

FOREIGN LETTERS

CANADA

Council on Hospital Accreditation.—The program of the newly formed Canadian Council on Hospital Accreditation was formally inaugurated in Toronto in January at a ceremony with the Honorable J. Waldo Monteith, Minister of National Health and Welfare, as principal speaker. Noting that previous accreditation programs had been a joint United States-Canadian effort and that all accreditation in Canada would now be dealt with by Canadians, Mr. Monteith stressed the fact that, although the program's achievements were important, the way in which they were obtained was even more important. The program had not been imposed from above by government or any other authority, and in spite of the introduction of hospital insurance the government had no desire to become involved in accreditation, realizing that this work was best done independently by those furnishing the services designed for improvement. On the very day on which the accreditation program began the government hospital insurance plan went into effect in a 6th and a 7th of the 10 provinces. The two undertakings were related, in view of the government's stress on improving standards of performance in hospitals. The government does not regard the insurance plan as merely a fiscal project but rather as a service program, and the resources available from government sources should encourage hospitals to meet accreditation standards.

Nutritional Deficiencies in Mental Patients.—It has been asserted that vitamin deficiencies are important contributory factors in certain organic psychoses associated with alcoholism and senility. It has also been suggested that secondary nutritional deficiencies are common in patients with certain psychiatric disorders. There is, however, little factual data on the nature and extent of nutritional deficiencies among mentally ill patients. Gregory and Paul (*Canad. M. A. J.* 80:186, 1959) attempted to compare the incidence of various nutritional deficiencies in certain groups of psychiatric patients at the time of admission to a mental hospital, before being placed on a standard diet. They studied 312 mental hospital patients and compared the results with those in 71 hospital employees. Analyses were made for deficiencies in the vitamin B group, ascorbic acid, vitamin A, carotene, and protein. When the patients were classified in such diagnostic groups as schizophrenia, affective psychoses, organic psychoses of senility, psychoneuroses, and alcoholism no statistically significant variations in the incidence of deficiencies were found. Although lower rates of relative deficiencies in certain vitamins were noted among hospital employees, these findings were related to marked and significant fluctuations in incidences of deficiencies recorded through the progress of the investigation.

Surgical Results of Mitral Valvotomy.—A series of 103 consecutive cases of mitral stenosis were operated on by the same surgeon in Montreal, and 95 of these were followed up by the associated cardiologist who has reviewed the results (*Canad. M. A. J.* 80:168, 1959). Patients were selected for operation according to currently accepted criteria. The follow-up study suggested that the absence of an opening snap or rather a sound heard in diastole in the mitral area, if combined with heavy calcification of the leaflets, was a poor prognostic sign, probably contraindicating operation. As regards mitral regurgitation, increasing importance was attached to the apical systolic murmur, and the correct diagnosis was made in 25 of 29 patients who had mitral stenosis with insufficiency. A positive diagnosis of tricuspid regurgitation may be made if Carvallo's sign is positive, the apical systolic murmur diminishes on treatment, and cardiac catheterization reveals diagnostic pressure curves in the right auricle. The operative risk was small (less than 2%) and could be reduced further if patients were operated on before the late stages of cardiac enlargement, immobile mitral valves, or incompletely controlled heart failure was reached. The results were worth while, even in those with mitral regurgitation, provided there was sufficient stenosis to relieve and the valve leaflets were mobile.

District Care for Mental Patients.—The Health Minister for Ontario reviewed plans for a radically new program in the treatment of mental illness. His plans will make treatment available at the community level, involve segregation of 12,000 hopelessly ill mental patients, and allow for diagnostic and treatment centers in larger cities with a sufficient staff to carry on outpatient day care, night care, and short-term inpatient treatment. The family physician will be able to refer his patients to the local mental health center just as he would to other specialized centers, and commitment papers will no longer be necessary for admission. Mental hospitals will be divided into units of 250 to 300 beds, each with its own staff, and research will be

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

arranged not only for short-term but also for long-term patients, because the major problem in psychiatry is the cause and cure of schizophrenia and most long-term patients are schizophrenic.

Spinal Traction.—One of the advantages of spinal traction in painful back and neck conditions has allegedly been vertebral separation. Lawson and Godfrey (*M. Services J. Canada* 14:762, 1958) therefore examined radiologically a group of 22 patients before and during cervical or lumbar traction at Sunnybrook Hospital, Toronto. For cervical traction they used an overhead suspension with a head sling, and for lumbar traction they used a Scott traction frame. They found that spinal traction with weights up to 100 lb. on the cervical area or 150 lb. on the lumbar region for varying periods resulted in no significant separation of the vertebrae, although cervical traction resulted in a slight temporary increase in height.

DENMARK

Hypofibrinogenemic Hemorrhage in Pregnancy.—Ejby-Poulsen and Brandt-Nielsen (*Acta obst. et gynec. scandinav.* 37:472-481, 1958) treated five patients who had hypofibrinogenemic hemorrhage by means of fibrinogen infusion. These included three who had premature separation of the placenta, one in whom it occurred during cesarean section where the possibility of intravascular escape of the amniotic fluid was present, and one who had a manual removal of the placenta and in whom plasminogen activator was demonstrated in the blood. The mode of origin in this last patient was thought to be that plasminogen activator from the uterine muscle entered the blood stream after trauma from the uterine muscle at intrauterine operation. All five patients were treated with fibrinogen made from human plasma at the State Serum Institute, Copenhagen, with subsequent rapid reestablishment of the clotting ability of the blood. No severe complications that could reasonably be attributed to fibrinogen infusion were seen.

FINLAND

Tuberculous Laryngitis.—Indirect minor laryngoscopy of 350 tuberculous patients was made at Satakunta Sanatorium by Palva and Huhti (*Acta tuberc. scandinav.* 36:125-132, 1958). Active tuberculous lesions were found in 3.5% and inactive and old fibrotic lesions in 2.5%. Active, long-standing tuberculous laryngitis was associated with far-advanced pulmonary disease of long duration and resistant to treatment. Antituberculous medication in these patients generally removed the pain, whereas the laryngeal changes remained stationary. These resistant infections represented about 25% of the total of the laryngeal lesions, while 75% healed well with streptomycin, PAS, and isoniazid combined. The authors concluded that routine examination of sanatorium patients by the laryngologist was not necessary, but that all patients presenting laryngeal trouble, even in the form of slight hoarseness, should be carefully examined.

17-Hydroxycorticosteroid Levels After Electroshock.—The effect of electroshock and electrostimulation and of emotional factors on the content of free 17-hydroxycorticosteroids in plasma were studied in 12 patients after electroshock therapy, in 5 after electrostimulation, and in 6 controls by Kallio and Tala (*Acta endocrinol.* 30:99-108, 1959). The control level of free 17-hydroxycorticosteroids in the plasma before the electroshock was 19.6 mcg. per 100 ml. The electroshock caused an increase of 9.8 mcg. per 100 ml. in the mean content of free 17-hydroxycorticosteroids in the plasma after 15 minutes. The rise was of short duration. Even after three hours the mean level was lower than before the electroshock. The wide individual variations were thought to be due to the fact that electroshock does not cause maximal stimulation of the adrenal cortex and its metabolic factors. The control level of free 17-hydroxycorticosteroids in the plasma before electrostimulation was 16.9 mcg. per 100 ml. After a slight electrostimulation with no convulsions there was an increase of 5.9 mcg. per 100 ml. in the mean level of free 17-hydroxycorticosteroids in the plasma. In the control subjects no significant changes in the mean content of free hydroxycorticosteroids were observed. The authors concluded that emotional factors had no or little influence on the rise of free 17-hydroxycorticosteroids in the plasma observed after electroshock and electrostimulation and that electroshock and electrostimulation cause a rapid but transient activation of the adrenal cortex.

Psychic Disturbances After Thyroidectomy.—A series of 53 patients who within five years prior to the examination had undergone thyroidectomy were reported on by Henrik Carpelan (*Finska läk.-sällsk. handl.* 101:60-67, 1958). Of the 46 women in the series 16 had preoperatively suffered from exophthalmic goiter or toxic adenoma, whereas 21 were nontoxic and with 9 the diagnosis remained uncertain. Only two of the seven men had been toxic prior to the operation. Eight of the patients were psychotic. Among the formerly toxic patients depressive and neurasthenic features dominated. In the nontoxic patients the main blame was laid to the faulty preoperative diagnosis, but different psychodynamic factors in connection with the operation and the organ involved were contributory. In the toxic patients the psychopathological sequelae were due mainly to psychic factors inherent in the psychogenesis and psychodynamics of thyrotoxicosis. The author stressed the importance of the doctor-patient relationship for the outcome of the operation on the basis of comparison with 28 patients who postoperatively had not needed psychiatric care.

Gastroscopy.—The roentgenographic and gastroscopic findings were correlated in 71 patients in whom the diagnosis was established at operation or at autopsy by Marcus Sundberg (*Finska läk-sällsk. handl.* 101:38-47, 1958). Of 29 patients with ulcer the x-ray diagnosis was found correct in 72.4% and the gastroscopic diagnosis in 55.2%. Of 28 with carcinoma, the x-ray diagnosis was conclusive in 53.6% and the gastroscopic in 75%. Of five patients with polyposis, the x-ray diagnosis was correct in 60% and the gastroscopic in 80%. In nine additional patients, the operation did not reveal any lesions in the stomach. The gastroscopic diagnosis was correct in all these patients, whereas the x-ray examination was conclusive in only 22.2%. The author commented that gastroscopy was of value as a complementary diagnostic procedure. This value was elucidated by the fact that of 28 patients with carcinoma 4 were detected only by gastroscopy and that in 2 additional patients with carcinoma and 3 with ulcer gastroscopy confirmed an uncertain x-ray diagnosis.

Reticulocyte Reaction in Hypoxia.—Krister Nordström (*Finska läk.-sällsk. handl.* 101:48-59, 1958) reported that 143 volunteers were subjected to hypoxia, the inhaled air containing varying amounts of oxygen. The tests aimed at revealing the sensitivity of the bone marrow to oxygen fluctuations as indicated by the reticulocyte reaction. Lowering of the oxygen saturation of the blood to 82% or less by breathing 13.5, 12, 11, 10, and 9% oxygen resulted in one or more relative reticulocyte counts exceeding the higher of the two control values. Five blood samples were taken within two hours after the test, and the reticulocytes were counted in the same period. The magnitude of increase was 20%. The error of the method in the control series was 12%. Lowering of the oxygen saturation of the blood to 93 and 85% by breathing 18, 16.5, and 15% oxygen and in some instances 13.5 and 11% resulted in a 16% increase in the reticulocyte count of half the subjects. In the others within the same saturation area, decreased values of the same magnitude occurred. This division was not due to the dispersion of the method, as true increases and decreases were recorded. In the phase of increase, the reticulocyte reaction was often associated with a shift to the left, followed by rapid reversion to the normal distribution of cells of the various groups of maturity or by a negative phase combined with a shift to the right. The negative and the positive phases were frequently of equal magnitude. The negative reaction was often combined with a shift to the right. The course of the reticulocyte reaction, as seen from the variation in total figures and as a shift in the distribution of cells in the different groups of maturity, favored the assumption of there being an adjusted accelerated speed of maturation in connection with oxygen deficiency. No definite conclusions were reached by the author as to the effect of hypoxia of short duration on the reaction of the erythrocytes.

FRANCE

Hospital Teaching Reforms.—On Sept. 17, 1956, an interministerial board under the presidency of Prof. R. Debré, president of the National Academy of Medicine, was created to study hospital teaching. This committee ascertained that the number of professors had not increased in proportion to the number of students and that university teaching was too theoretical and was lacking in clinical application. The board proposed to modernize teaching by dividing it into three phases. The first three years of medicine would be dedicated to basic sciences and to elementary clinical work. In the next three years students would spend their entire time in the hospital and university clinics. The third phase would be limited to future researchers. The project proposed to reduce the competition for the externships and to unify hospital and university functions and careers in such a manner that the medical care of patients, teaching, and research would be the responsibility of the same faculty members. Their recruiting would be carried out by national competition among the interns. Faculty positions would be on a full-time basis.

Congress of Allergists.—At the Third Congress of Allergists in Paris, in October, Sidi and co-workers reported that they treated 15 patients who had eczema by placing 20 to 50 mg. of heparin under the tongue daily for one to three months. Of these 11 showed marked improvement.

ICELAND

Leprosy.—Gudmund Benediktsson (*Laeknabladid* 42:71-80, 1958) stated that the incidence of leprosy had decreased in Iceland. In 1901 there were 169 lepers; in 1920 there were 67; in 1940 there were 22; and in 1958 there were 8. A new case was reported in 1957 in a 60-year-old woman. From the ages of 6 to 18 years the patient had lived with her aunt, who suffered from leprosy, but since then she had not been in contact with any person known to be suffering from the disease.

INDIA

Oxytocics in the Third Stage of Labor.—M. D. Adatia (*Journal of the Indian Medical Profession,* vol. 5, December, 1958) studied the comparative merits of methylergonovine and a combination of ergotamine and ergonovine in the management of the third stage of labor. Of 100 consecutive patients, 46 received methylergonovine and 54 received the mixture. These two drugs are now commonly used in the third stage of labor and the former is claimed to possess oxytocic properties superior to those of ergonovine as regards speed and duration of action. Ergonovine combined with ergotamine is supposed to have a more lasting oxytocic effect than ergonovine alone. Thirty patients were given 1 cc. (2 mg.) of methylergonovine intramuscularly and 16 were given the same dose intravenously. The dosage of the mixture was 1 cc. (2.5 mg.) of ergotamine tartrate and 0.125 mg. of ergonovine tartrate. It was given intramuscularly to all except 18, who received it intravenously. The average amount of blood loss after methylergonovine was about half of that lost after the use of the mixture. The oxytocics had a more pronounced action in multiparous women in controlling the blood loss. Methylergonovine also caused a greater reduction in the duration of the third stage of labor. This capacity had no relation to parity.

The fundal height immediately after expulsion of the placenta did not vary significantly in the two series. Thus the action on uterine contraction of the two preparations was about the same. Daily palpation of the fundus to evaluate involution revealed an equally satisfactory involution in the two series. Estimation of blood pressure showed a significant elevation of blood pressure after the administration of the mixture as compared to the other group, where it was hardly affected. No complications such as retention of the placenta were met with in either group. On the whole, methylergonovine was found to be a more efficient oxytocic than the combination of ergonovine and ergotamine, both as regards control of blood loss and duration of the third stage of labor. The absence of serious side-effects and lack of pressor action were further advantages.

Self-sufficiency in Medical Supplies.—India will soon achieve self-sufficiency in the matter of her requirements of drugs and x-ray equipment. The Soviet delegation which toured the country in the first week of October, 1958, investigated the possibility of setting up four plants for the manufacture of certain drugs that have not hitherto been manufactured in India. In 1957, India imported about 27 million dollars worth of drugs from foreign countries in spite of the great progress she had made in the last 10 years in this direction. The Soviet-Indian Commission will finance and work five different projects according to the report they presented to the Ministry of Industries. These are the manufacture of synthetic drugs, alkaloids from Indian medicinal herbs, surgical equipment, antibiotics, and hormones. For these projects, the Soviet Union has offered credit facilities as well as technical assistance.

Planned Parenthood.—In a paper read before the International Conference on Planned Parenthood in New Delhi in February, S. Chandrasekhar described the work carried out by a rural clinic established by the Indian Institute for Population Studies in Madras. The experience gained at this clinic gives cause for hope that a program to limit the expansion of population can succeed in rural India. It shows that by and large the traditional conservative attitude has disappeared and that there is a healthy desire for knowledge. This clinic was established by the institute three years ago. The institute conducted a census in the village and nine adjacent hamlets in January, 1956. It was found that the total number of married women between the ages of 15 and 45 was 673. In course of time the staff of the clinic contacted all those women. Of them, 632 were persuaded to visit the clinic. They were convinced of the need to limit the size of their families either because they could not afford another baby or because their health was poor.

During the period of observation, ranging from 2 to 20 months, 192 of these women conceived because they did not use contraceptives. Though the remaining 440 women have not conceived, the success of the experiment has not been established beyond doubt. The birth rate at the end of five years must be calculated before a conclusion can be reached. The village in question is representative of the country in every sense. An attitude survey showed that 72% of the couples did not want more children; 55% of the husbands and 58% of the wives were in favor of family planning through the use of contraceptives. Discussion with the villagers revealed a profound ignorance of the subject. Under the present socioeconomic and cultural conditions prevailing in Indian villages, the easiest and most effective way to solve the problem seems to be either vasectomy or salpingectomy. Of these two surgical methods of permanent conception control, vasectomy should be given the widest publicity, according to the author.

At the sixth meeting of the Central Family Planning Board in New Delhi in February, the Health Minister said that the day was fast approaching when the government would have to provide family planning facilities on a universal scale at almost every place where medical and public health centers existed. The urgency of the population problem for India was underlined by Sir Julian Huxley who said that India's failure to solve the problem would mean political and social disaster for the country. India's population, at its present rate of increase, would double itself in the next 45 years. This explosive increase must be checked, if India is to develop economically. From a purely economic point of view, expenditure on population control measures would be one of the most profitable forms of investment for India.

Spinal Arachnoiditis.—A. Singh and co-workers (*Journal of the Association of Physicians of India,* vol. 7, January, 1959) observed several cases of paraplegia of a type which was formerly labeled as "obscure paraplegia" but which was actually spinal arachnoiditis. Thus of 100 patients with paraplegia who were investigated fully, spinal arachnoiditis was detected in 10. In four the diagnosis was confirmed by laminectomy while in the rest it was based on clinical findings and investigations such as myelography. Most of the patients were farmers between 15 and 50 years of age who had been leading an active life. All complained of progressive weakness starting in one lower limb and spreading quickly to the other limb or starting simultaneously in both. Five had root pains. Sphincters were involved in later stages in all but one, starting with hesitancy of micturition and going on to urinary retention with overflow. Six patients gave a definite history of trauma, which was also evident radiologically in five.

The higher cerebral functions and cranial nerves were unaffected while almost all showed the classical signs of spastic paraplegia. Three patients also showed evidence of upper motor neurone lesions in the upper limbs. Five had sensory disturbances. In three the paralysis had reached the stage of paraplegia in flexion and in seven it was still in the stage of paraplegia in extension. Roentgenograms of the spine showed either evidence of old injury in the form of wedging of one vertebra, narrowing of an intervertebral space, or localized osteoarthritis in all but one. Spinal manometry showed the presence of complete block in the subarachnoid space in five. The cerebrospinal fluid showed marked increase in proteins in six. Myelography was performed in nine and showed a complete blocking of the dye in two and a delay in its transit in two others. Laminectomy was performed on four patients. One of these became worse after operation and the other three showed slight improvement but none of them made a complete recovery.

Operations on the Rheumatic Heart.—R. H. Betts and co-workers (*Journal of the Indian Medical Association,* vol. 32, Jan. 16, 1959) stated that rheumatic heart disease is almost as common in India as in the Western countries. They have not operated for aortic stenosis but four patients with aortic regurgitation were operated on and Hufnagel valves inserted in the descending aorta. All four patients were improved after operation and the improvement has been maintained. The authors believed that operation on the mitral valve for any reason but the relief of symptoms is not justified. They strongly recommend that all patients suffering from rheumatic heart disease be referred to a cardiologist for assessment of the possibility of surgical relief as soon as symptoms develop, instead of being offered a long course of medical therapy. The best results from mitral valvulotomy were obtained in patients with pure mitral stenosis.

Operative treatment should be offered at any stage of the disease provided mitral stenosis is the predominant lesion and the patient can withstand the operation. The ages of the patients in the authors' series varied from 9 to 40 years. Patients under 20 with symptoms are commonly seen in India. Operation should be avoided in the presence of clinically demonstrable rheumatic activity as long as improvement continues. The presence of slight to moderate mitral regurgitation does not necessarily mean that a good result will not be obtained, although it is less certain in such patients. Auscultation alone is unreliable in evaluating the patients with prominent apical systolic murmurs. The presence of an apical systolic murmur, even though loud, in a patient with mitral stenosis does not always mean that the patient will not be benefited by a valvulotomy. If the associated diastolic murmur is not definite, the lesion is usually purely regurgitative.

Cardiac catheterization helps in recognizing significant degrees of mitral insufficiency. Forty patients were subjected to cardiac catheterization. Several of them who had loud systolic murmurs but no evidence of regurgitation were benefited by operation. The presence of auricular fibrillation is not a contraindication to operation. Such patients do well if the ventricular rate is controlled by digitalis. Some patients with a cardiothoracic ratio of 60 to 70% have had excellent functional postoperative results. Moderate cardiac enlargement does not preclude surgical treatment. A series of 123 patients with mitral stenosis were operated on. Most of them were improved after operation; 18 died.

Pulmonary Amebiasis.—G. Victor (*Antiseptic,* vol. 55, December, 1958) reported a series of 15 patients with pulmonary amebiasis, the youngest being 16 years old and the oldest 62. Cough with expectoration and pain over the right lower portion of the chest were the common presenting symptoms, others being fever, abdominal pain, nausea, anorexia, dyspnea, and swelling in the abdomen and right side of chest. One patient raised blood-stained sputum. Only four patients gave a history of dysentery, the minimum interval between the occurrence of intestinal amebiasis and onset of pulmonary symptoms being 1 month and the maximum 12 months. Clinically, there was dulness to percussion over the base of the right lung, diminished respiratory movements, and presence of rales and rhonchi in most patients. The liver was palpable and tender in 13. The total leukocyte count varied between 5,200 and 16,800, the polymorphonuclear cells being predominant in 10 patients while the lymphocytes were increased in 5. One patient had an eosinophilia of 22%.

The sedimentation rate ranged between 5 and 120 mm. Stools contained cysts of Entameba histolytica in two patients only, two others showing Ancylostoma and whipworm ova. Only one patient had chocolate colored sputum containing trophic forms of E. histolytica, two others showed staphylococci and streptococci, and two others showed only pus cells. Sigmoidoscopic examination revealed a granular mucosa, with mucus and blood, in only one patient. Radiologically all the patients showed involvement of the right side of the chest. Treatment consisted of such drugs as emetine, diiodohydroxyquin, and chiniofon enemas. Both clinical and radiologic response was observed with medical treatment in all but one patient and he left the hospital against medical advice.

Peculiar Jaundice.—The recent outbreak of jaundice in Malda, West Bengal, was found to be viral in origin. Two physicians from the Calcutta School of Tropical Medicine, after studying the disease on the spot, brought specimens of blood and stools of some of the persons attacked for examination. The virus was suspected to have been carried from Nepal by a group of laborers. The disease started spreading within a short time and attacked about 90 persons in one village. It did not, however, spread to other villages and there were no deaths. Unlike the common type of infectious jaundice, this variety was very infectious and very acute.

Brucellosis in Children.—T. N. Mathur stated that brucellosis in children is not so rare as is usually supposed. In addition to the 11 cases reported earlier, he has reported another 13 cases in the *Indian Journal of Child Health* (vol. 8, January, 1959). These patients were first given a diagnosis of chronic tonsillitis, typhoid, malaria, amebic hepatitis, secondary syphilis, pulmonary tuberculosis, tuberculosis of the hip, and sciatica. Typhoid was the most common erroneous diagnosis and, as chloramphenicol brings about cure of both diseases, often no further investigations were made. Only 6 of the 13 patients complained of pain in the joints. Joint pains are thus not an important feature of the disease in children. All the patients but two showed a significant titer of agglutination for Brucella antigen. Two showed blood cultures positive for Brucella melitensis. Of the 13 patients, 2 came from rural areas, 3 had contact with cattle, 2 had drunk unboiled milk, and 4 denied having done so. Brucellosis should be looked for in all children with unexplained fever, even if there is no definite history of contact with cattle, sheep, or goats.

Chloramphenicol Therapy in Children.—P. N. Taneja and co-workers (*Indian Journal of Child Health,* vol. 8, January, 1959) described the toxic effects of chloramphenicol noted during short-term therapy with this drug in children. A series of 748 children suffering from different diseases were treated with chloramphenicol. Total and differential leukocyte counts were made twice a week or more often if necessary. Of the total number 91, or 12%, developed complications due to the drug. These included hematological complications (granulocytopenia, pancytopenia) in 31, stomatitis in 35, diarrhea in 20, vomiting in 3, and allergic rash in 2. The average dose of the antibiotic used in this series was 50 mg. per kilogram of body weight per day. The duration of treatment varied from less than a week to three weeks.

Most of the complications developed in the first two weeks of treatment. Thus granulocytopenia was noted in 27, more often by routine blood examination than by clinical manifestations. Of the 27 patients 23 showed no clinical manifestations. Granulocytopenia appeared at the earliest on the 3rd day and the maximum interval was 10 days. Four patients developed this complication while still receiving cortisone or ACTH along with the antibiotic. Some patients reacted promptly to withdrawal of chloramphenicol but others had not recovered when last seen. Pancytopenia occurred in one 7-month-old child who had received the drug for seven days. He was brought to hospital for a sudden pallor of one day's duration and was afebrile at the time. He recovered with blood transfusion and penicillin therapy. A fall in hemoglobin level occurred in one patient on the fifth day of treatment. Methemoglobinemia was noted in one patient who was also receiving cortisone. Stomatitis, varying in intensity from mild to severe, occurred in 35 patients, in 2 of whom the drug had to be withdrawn because of the severity of this complication. This complication occurred after varying periods of treatment, the shortest being 1 and the longest 12 days.

Twenty patients who developed diarrhea showed a marked improvement on changing over to parenteral therapy. Parenteral therapy was also resorted to with favorable results in the three who developed vomiting. The allergic rash disappeared in one patient on withdrawal of chloramphenicol and administration of antihistaminics while the other patient with this complication died of aspiration pneumonia. The age of these patients varied from less than 1 year to 12 years and the largest percentage of complications occurred in those between 3 and 6 years old. Cortisone and ACTH did not prevent the occurrence of hematological complications. The incidence and severity of complications were independent of the dosage used, marked granulocytopenia having been noted even when only 25 mg. per kilogram of body weight per day was given. The degree of depression in the leukocyte count had no prognostic value as regards the speed of recovery, although the earlier the complication was detected the better the prognosis.

Patients showed variable response to withdrawal of the drug. Those with granulocytopenia or pancytopenia without any clinical manifestations had a better prognosis than those with manifest complications. Of the 5 who had clinical manifestations of hematological complications, 3 died in the hospital and 1 left in a poor condition, but the 26 with nonmanifest hematological complications all survived. All those with stomatitis were already receiving multivitamin and vitamin B complex preparations. Thus probably some other factors were responsible for this complication. Vomiting and diarrhea were possibly due to the local irritating effect on the mucosa and patients with these conditions responded on changing the route of administration to parenteral.

Encephalitis.—Patel and Tandon (*Current Medical Practice*, vol. 3, January, 1959) treated 11 patients who had encephalitis. Besides symptomatic treatment and maintenance of fluid and electrolyte balance, these patients were given tetracyclines and steroids. The antibiotics were given parenterally at first and later orally as the general condition improved. In severe cases the drug was given in a dosage of 100 to 250 mg. by slow intravenous infusion every eight hours, and in mild cases 100 mg. was given every eight hours till the fever came down. This was continued for three or four days after the temperature reached normal and remained so. The steroids used were ACTH, corticotropin gel, and prednisolone. A slow intravenous infusion of 25 units of ACTH per day spread over six to eight hours was given. The gel was given in a dose of 40 units per day intramuscularly, and the dose of prednisolone was 10 mg. every eight hours, the dose being gradually reduced as the condition improved.

The slow intravenous infusion of ACTH was the treatment of choice as it gave a prolonged action with a minimal amount of the drug. Seven of the 11 patients recovered. In five of these fever came down within 48 hours of starting therapy with the antibiotics and steroids. Headache persisted in most patients for about a month after the fever came down. The spinal fluid sugar level came down to normal with clinical recovery while the cells and proteins also showed a fall. The average stay in hospital was 10 to 15 days. Sequelae were noticed in only one patient in the form of a slight mental imbalance. On the whole the results were encouraging with the combined use of broad-spectrum antibiotics and steroids.

ISRAEL

Uptake of Radioiodine by the Infarcted Heart.—At a meeting of the Israel Medical Association in Jerusalem, F. Dreyfuss and co-workers reported on the results obtained when radioiodine (I^{131}) was given to four patients with a recent anterior wall myocardial infarction, six with posterior wall infarction, and nine controls. They were given 100 to 200 μc of carrier-free I^{131} by mouth. The patients with infarction were usually examined within three weeks after coronary occlusion. Readings were made by exploring the precordium with a scintillation counter. Readings were taken at 30-minute intervals for the first six hours, followed by daily readings for one to three weeks.

A definite difference was found in the counts in patients with myocardial infarcts and the controls. In the first six hours after the administration of I^{131} absolute counts of 10,000 to 40,000 per minute were obtained over the precordium in all patients. One day later counts of 1,600 to 4,500 were observed in the controls, but the counts in the patients with infarcts on the corresponding day were higher and ranged between 6,350 and 9,000 for anterior wall infarcts and between 3,000 and 5,500 for posterior wall infarcts. They continued to be higher in the patient group 48 hours and six or seven days, respectively, after the ingestion of I^{131}. For the first few hours higher readings were obtained over the heart than over the right side of the chest in all subjects. This phenomenon was explained by the initially high level of circulating I^{131} before it was cleared by the thyroid, kidneys, and liver. The difference observed after 24 to 48 hours and six to seven days must be caused by a significant uptake of I^{131} by the infarcted heart.

One of the patients with posterior wall infarction died seven days after the administration of I^{131} as a consequence of his severe cardiac lesion. At autopsy on the following day two infarcted areas were found. In both of these areas the concentration of I^{131} was about 50% higher than in the intact heart muscle. Tissue samples taken from the intact areas were tested for radioactivity. The homogenized material from the infarcted areas had concentrations of I^{131} 50 and 70% higher, respectively, than the intact myocardium. Necrotic heart muscle apparently takes up more I^{131} than heart muscle not so affected.

NORWAY

Dissecting Aneurysm.—In a series of about 700 cerebral angiographies by means of the usual percutaneous technique, three deaths were reported by Kjell Liverud (*J. Oslo City Hosp.* 8:209-241 [Nov.-Dec.] 1958). In these three cases an obliterating dissecting aneurysm developed on the injection of the contrast medium at the site of puncture of the common carotid artery. Death was attributed to obliteration of the carotid artery. The investigations were made by three investigators, which makes it unlikely that it was due to an individual mistake in technique. The accident was caused by the sharp tip of the needle in the vessel wall during injection. In order to prevent further accidents of this kind the author considered it essential to alter the technique and the sharp needle in the vessel was replaced by a flexible polyethylene catheter introduced percutaneously.

This procedure has the advantages of safe intraluminal injection; freer choice of projections; choice of internal, external, or common carotid angiography in the same investigation; easier diagnosis of carotid thrombosis; and better bilateral filling of the cerebral vessels during contralateral carotid compression. The patient is in a comfortable position between injections which may be made at longer intervals to reduce the action of the contrast medium on the cerebral vessels. The investigation may be performed by one man and take place in a quiet atmosphere as a routine procedure. By lengthening the catheter the exposure of the investigator to x-rays can be reduced. In rapid serial angiography the catheter may be connected with an automatic pressure syringe, and it is then not necessary for the investigator to stay in the radiography room for the numerous exposures. The procedure has been used as routine in about 1,000 cases without fatal complications.

Pyrazinoic Acid Amide and Cycloserine for Tuberculosis.—Birkeland and Nissen-Meyer (*Acta tuberc. scandinav.* 34:98-109, 1958) sudied a series of 30 patients with far advanced pulmonary tuberculosis and bacillary resistance to at least two of the principal antituberculous drugs; 13 were selected at random for treatment with pyrazinoic acid amide and 17 received this drug plus a small dose of cycloserine. The bacteriological and radiologic results of three months' treatment were on the whole modest in both groups; complete disappearance of cavities was not seen in any patients and sputum conversion in only a few. In the evaluation of these results, the type of case must, however, be considered. All patients had widespread cavitary disease of long duration and with extensive fibrotic changes. This type of patient generally responds poorly to medical treatment, and even without drug-resistant tubercle bacilli outstanding results could not have been expected from the best combination of our three principal drugs.

The results obtained with pyrazinoic acid amide and with this drug combined with cycloserine could not be compared with certainty because of the small number of patients in each group. The bacteriological and radiologic findings, however, suggested that pyrazinoic acid amide plus a small dose of cycloserine was more effective than pyrazinoic acid amide alone. The toxic effects of the drugs observed in the present series were all reversible. They were, however, so severe and unpleasant that the use of these drugs should be reserved for patients who cannot be treated with a combination of the principal drugs, either because of intolerance or because of bacillary resistance. If one of the principal drugs cannot be used, it should be tried in combination with one of the new drugs. Controlled trials have already shown that the effect of pyrazinoic acid amide combined with either streptomycin or isoniazid was comparable to any combination of the three principal drugs.

In patients in whom none of the principal drugs can be used successfully, treatment with pyrazinoic acid amide plus a small dose of cycloserine may be worth a trial, particularly if a successful medical treatment can make the patient fit for additional surgical treatment. Unfortunately, most patients with bacillary resistance to the principal drugs, like most of those in the present series, have processes which respond poorly to chemotherapy and a respiratory function which excludes surgical treatment. In such patients, the advantage of a moderate and perhaps temporary effect of the drugs must be weighed against the risk of possible toxic complications. A definite indication for pyrazinoic acid amide plus cycloserine will, however, be present in patients in whom surgical treatment of an old cavity in one lung is contraindicated by an acute spread to the other lung, which, because of drug-resistant tubercle bacilli, cannot be expected to respond to treatment with the principal antituberculous drugs.

PORTUGAL

Physiotherapy of Periarthritis. — Albano Ramos (*O Medico*, no. 365, 1958) stated that calcified periarthritis of the shoulder has an obscure etiology. Among the various causes suggested the most likely is direct or indirect trauma. A similar lesion appears rarely in the hip, elbow, or knee. The fibrous form of periarthritis lends itself to erroneous interpretation, as the roentgenogram does not define the diagnosis. This is not true of calcified periarthritis. Treatment includes drugs for the pain and muscular rigidity, adrenocortical hormones, surgical ablation of the calcarious deposits, physiotherapy (mobilization, galvanization, faradization, diathermy, and ultrasound). The author concentrated on radiotherapy. With this method he observed almost 85% of cures with an almost constant regression of calcification. The best means to fight this disease is, however, to prevent it. Immediately after an articular trauma the region should be irradiated, even through the plaster cast, for the earlier the radiation the greater the chances of nonformation of calcareous deposits. Their accumulation, forming large calcifications, reduces or delays the patient's chances of cure.

Spinal Amyotrophy.—Diogo Furtado (*Arquivo de Patologia* 30:522-532, 1958) stated that the fatal prognosis in patients with hereditary muscular atrophy, which was part of the classical conception of this disease, is being contested by several observers. The author observed a typical case of this disease, with biopsy and electromyographic confirmation of the diagnosis, which started when the patient was 2 years of age, progressed until he was 14, and then underwent remission. The prognosis is not therefore so grave as it was originally thought to be.

Cryptorchism.—M. Fernandez e Fernandes (*Gazeta Medica Portuguesa*, vol. 11, no. 3, 1958) reserved the term cryptorchism for irreducible or permanent absence of a testis within the scrotum, due to its detention in the physiological tract from the abdominal wall to the scrotum. Examination for cryptorchism should be performed repeatedly and with the patient in various positions. In cryptorchism the testis is never of normal size. The presence of the cremasteric reflex in a doubtful case indicates a probable pseudocryptorchism. Surgical correction should not be attempted before the age of 9 years, because a spontaneous descent of the testis may occur. This limit should, however, not be rigid since the psychosexual development should be considered more than the chronological age.

Hormonal therapy is indicated in all patients with cryptorchism without complications, in those with pseudocryptorchism in whom the definite fixation of the testis has not been established before the 10th year, and also in association with surgical cases, before and after orchiopexy. A dose of 300 to 500 units of chorionic gonadotropin may be given two or three times a week, not exceeding a total of 8,000 units. With very large doses there is danger of provoking the degeneration of the gonad. Testicular therapy, which may also cause precocious virilization, should be reserved for patients with pronounced sexual infantilism, with maximum doses of 10 mg. a day for two or three weeks, always combined with gonadotropins. In patients with hypothyroidism or adiposogenital dystrophy the use of thyroid extract is beneficial. Operation is indicated in patients with complicated cryptorchism, ectopic testis, persistence of the peritoneovaginal canal, concomitant hernia, accidents of torsion, inflammatory or carcinogenic processes, and in those in whom, after the age of 11 or 12 years, the hormonal treatment has produced no effect.

Iron and Cobalt in the Treatment of Anemia.—Soares and Moreau (*Gazeta Medica Portuguesa* 11:58 [May-June] 1958) stated that the intravenous use of cobalt chloride in patients with anemia had to be discontinued because of severe reactions even with doses too small to have an appreciable hematopoietic effect. On the other hand the use of a combination of iron and cobalt gave good results in patients with thalassemia, achylic chloroanemia, gastric anemia of Morawitz, acquired hemolytic idiopathic anemia, symptomatic anemia of acute rheumatism, and myeloid leukosis. The drug was well tolerated; no symptoms of thyroid hypofunction were observed, nor was there an increase of the size of the thyroid.

Aplastic Anemia.—Francisco Branco (*Arquivo de Patologia* 30:489-521, 1958) reported that damage to the marrow may be caused by benzene, trinitrotoluene, carbon tetrachloride, trichlorethylene (used in industry), lindane (an insecticide), paraphenylenediamine (used in hair dying), and thorium dioxide (a contrast medium). Drugs cited as possible causes of aplastic anemia include the organic arsenicals, gold salts, nitrogen mustards, alkaloids of colchicum, bismuth, mercury, and such antimetabolites as aminopterin and mercaptopurine. Thiouracil and other synthetic antithyroid drugs and such anticonvulsants as hydantoin and its derivatives, in spite of being regarded as responsible for refractory total medullary aplasias, are more likely to produce agranulocytosis.

Aminopyrine and quinacrine, especially when used continuously, have also been implicated. Some substances act merely as sensitizing agents in patients suffering from lability of the hematopoietic system, and this may explain why only a few of those exposed suffer from aplastic anemia. Such infections as miliary tuberculosis, leptospiral jaundice, syphilis, typhoid, brucellosis, malaria, and rheumatic fever may cause aplastic anemia. Excessive doses of streptomycin and, more frequently, chloramphenicol may also cause anemia. The poisoning effect of the latter may depend on the nitrobenzenic radical in its constitution.

SWEDEN

Combined Treatment of Tuberculosis.—Two new combinations of tuberculostatics—cycloserine-isoniazid and cycloserine-viomycin—were tried in the treatment of pulmonary tuberculosis and compared with the combination of PAS and isoniazid by I. Ståhle (*Acta tuberc. scandinav.* 34:83-97, 1958).

Cycloserine and isoniazid were given to 28, cycloserine and viomycin to 30, and PAS and isoniazid to 34 patients. The duration of treatment was three months. The tuberculostatic effect evaluated clinically and roentgenologically was fully comparable for all combinations and was somewhat better for therapy that included cycloserine. With cycloserine and viomycin, healing of cavities was remarkably good. It was not possible to study any development of resistance for in all patients the tubercle bacilli rapidly disappeared from the sputum. One patient showed initial resistance to cycloserine before treatment. The tolerance to both cycloserine and viomycin was excellent and no side-effects attributable to those agents were observed. Symptoms of intolerance to PAS and isoniazid occurred in a few patients however. Cycloserine and viomycin combined appeared to be of great value in the treatment of pulmonary tuberculosis.

Calcium Infusion Test for Sarcoidosis.—An intravenous calcium infusion was administered to 14 patients with sarcoidosis by Björn-Erik Roos (*Acta tuberc. scandinav.* 34:152-172, 1958). Nine of the patients were subsequently treated with corticosteroids and/or ACTH and three were treated with vitamin D. The patients were examined at intervals during and after the treatment. Earlier investigators showed that the urine phosphorus excretion in normal persons decreased during the intravenous administration of calcium. Only 2 of the 14 patients reacted in this manner. The others deviated in varying degree from the normal. During treatment both with corticosteroids and ACTH and with vitamin D, 11 of 12 patients so treated reacted normally to the administration of calcium intravenously. After the treatment, on the other hand, the reaction of all patients again deviated from the normal. If the 14 patients were regarded as a group, their reaction to the intravenous calcium infusion most closely resembled that observed earlier by other investigators in hyperparathyroidism. It appeared that patients with sarcoidosis might have an impaired calcium metabolism even when they do not have hypercalcemia.

Prolapse of the Uterus.—Sven Svennerud (*Acta obst. et gynec. scandinav.* 37:416-433, 1958) analyzed a series of 539 operations for prolapse of the uterus. The mortality was 1.3% and the frequency of recurrence 7.3%. In that part of the series in which the patients had the complete Manchester-repair, the frequency of recurrence was 4.6% as against 17.2% when either amputation of the cervix or colporraphy was omitted. Of 161 patients operated on before the menopause, the symptoms had appeared within one year of delivery in more than 50%, and of 388 patients operated on after the menopause the symptoms had appeared after the menopause in about 65%. Of the total number, 23% had undergone earlier complicated deliveries. Early ambulation after operation diminished the frequency of venous thrombosis from 6.5 to 3.1% and fatal pulmonary embolism decreased from five cases to none. In the group that was allowed to get up soon after the operation (163), the mortality was 0.6% compared with 1.6% of the 376 patients who rested in bed for 14 days after the operation.

The frequency of urinary tract infection also diminished, as did the length of stay in hospital after the operation (30%) with early ambulation. Administration of estrogens before and after operation promoted primary healing. Healing by second intention occurred three times as often among those who had not received estrogens. Estrogen treatment produced some ascent of the uterus and thereby made the operation more difficult. It was therefore possible that in such patients the operation might not be sufficiently radical and the risk of recurrence might thereby be increased. Of the 539 patients operated on, 1 developed carcinoma of the uterus, 3 developed ovarian carcinoma, 4 mammary carcinoma, and 14 carcinoma of the colon, stomach, or liver. Twenty-five pregnancies occurred in 15 women after the operation and the frequency of abortion was 40%. Cesarean section was not necessary and delivery was in no case complicated. The risk of recurrences after vaginal delivery was relatively small. The author concluded that the Manchester operation should always include amputation of the cervix except in young women who wish to have children later. Delivery after operation can be performed by the vaginal route. Any injury to the levator ani should be sutured at the time of delivery.

Blood Loss at Delivery.—In 18 obstetrically normal women the total amount of hemoglobin in the body (THb), the hemoglobin concentration (Hb), and the hematocrit (Hct) were measured repeatedly in peripheral blood before and after delivery by Robbe and Ström (*Acta obst. et gynec. scandinav.* 37:448-471, 1958). The maternal external blood loss at and after delivery was carefully estimated. Repeated THb measurements were made after delivery in an additional nine normal women. Measurements of the plasma volume were made before and after delivery in 9 of the 27 women. The maternal THb before delivery was slightly overestimated (by 1 to 2%), when the alveolar carbon dioxide method was used because of fetal uptake of carbon dioxide. This error was corrected.

Maternal blood loss in the placenta was estimated as 20% of the placental weight. The total maternal external blood loss at delivery and during the first week after delivery averaged 547 ml. of whole blood (202 ml. of red blood cells). At delivery and during the first two hours after delivery, 84% of the total external loss occurred. The decrease of THb up to the seventh postpartum day corresponded to a loss of 961 ml. of whole blood (355 ml. of red blood cells). The unexplained difference, 414 ml. of whole blood (153 ml. of red blood cells), was statistically highly significant. The unexplained disappearance of erythrocytes mainly occurred between a few hours before delivery and two hours after delivery. The magnitude of the unexplained difference was not correlated to the amount of the external blood loss. The plasma volume determinations were not judged to be reliable during labor. After delivery the body Hct averaged 90% of the peripheral Hct.

Prolonged Pregnancy.—L. Lindgren and co-workers (*Act obst. et gynec. scandinav.* 37:482-496, 1958) stated that they treated prolonged pregnancies conservatively. A higher proportion of male and first-born infants belonged to the group of prolonged pregnancy as compared to the group of delivery at term. The perinatal death rate for prolonged pregnancy was twice that for delivery at term. Prior to labor there was no difference between the fetal mortality rates for prolonged pregnancy and delivery at term. Asphyxia and cerebral hemorrhage accounted for the increase in the perinatal death rates during and after labor. It was found that a high birth weight did not involve the risk of increasing the fetal death rate or danger of asphyxia and cerebral hemorrhage, provided that the patients in whom cephalopelvic disproportion was diagnosed clinically were delivered by cesarean section. The incidence of forceps delivery and the proportion of fetal deaths associated with it were higher in cases of prolonged pregnancy. The rise in the perinatal death rate for prolonged pregnancy was above all observed in cases of primary uterine inertia and threatened asphyxia: the higher death rates were due (1) to the higher incidence of and higher fetal death rate for primary uterine inertia, and (2) to the higher incidence of and high fetal death rate for threatened asphyxia.

The Prediabetic Period and Obstetrics.—Lars Hagbard (*Acta obst. et gynec. scandinav.* 37:497-518, 1958) analyzed 274 pregnancies in 113 women who subsequently developed diabetes. In all these women the disease developed during their childbearing years and in most before the age of 40. No increase in the incidence of abortion was observed in these prediabetic pregnancies. There was an unusually large proportion of oversized babies (birth weight over 4,500 Gm. or 10 lb.) in that series, particularly during the last two years prior to the diagnosis of the maternal diabetes, i. e., 26.7% compared with 1 or 2% (the normal percentage). The perinatal mortality was much higher during the five years preceding diagnosis. In the two years before diagnosis 37.3% of the babies were lost perinatally. Spontaneous premature labor (before the end of the 37th week) occurred in 17.4% and in the last two years before the diagnosis 26.2% were born before the end of the 37th week. A significant proportion of the children of these prediabetic mothers showed a congenital deformity, i. e., 4% compared with 1.7% in a normal control series.

As it was believed that these complications might have been due to a disorder of the maternal carbohydrate metabolism during the prediabetic period, it was decided to make glucose tolerance tests on all women giving birth to children weighing over 4,500 Gm. These tests were also made on a number of women with an obstetric history of severely deformed or stillborn infants and in whom no obstetric or other cause of the complication was found. Altogether 189 women were examined on the fourth or seventh day after delivery. A control series of 100 women was identically examined. It was found that the average value for the blood sugar both 60 and 90 minutes after administration of glucose was significantly higher in the test series than in the control series. Using a maximum value of 220 mg. per milliliter and/or a two-hour value of 120 mg. per milliliter as criteria of abnormality, 37 or 19.6% of the test series proved to have abnormal glucose tolerance curves compared with 4 or 4% of the control series.

The high incidence of fetal complications during the prediabetic period was probably due to the fact that some of the mothers had transient unrecognized diabetes during pregnancy or at any rate had a lowered carbohydrate tolerance several years before the disease was manifest. The author believed it was not correct to use the terms prediabetic pregnancy and prediabetic state in the sense they had hitherto been used.

UNITED KINGDOM

Little Danger in Trumpeters' Loud Notes.—Prof. M. Faulkner, a professional player and teacher of the trumpet, and Prof. E. P. Sharpey-Schafer, a physician, reported in the *British Medical Journal* of March 14 on their investigations into the dizziness and occasional blackouts suffered by trumpeters when they play high, loud notes. They concluded that the musicians are not likely to come to any harm. Measurements were made as Professor Faulkner blew his hardest and loudest. Measurements were made on two other subjects, a surgeon who played the trumpet as a hobby and a novice purported to be learning the oboe. Because of the dizziness hazard many leading orchestras carry an assistant to take over from the first trumpeter in prolonged difficult passages. Wagner is said to be the composer with least consideration for the feelings of the trumpet player. A long phrase from Wagner's "Tannhäuser" was played by Professor Faulkner without drawing breath. Then he blew a loud arpeggio up to high D. On the top note he reached a pressure more than three times as great as that normally used by doctors to test circulation.

The circulatory effects of trumpet playing were similar to a forced expiratory effort with nose and mouth closed. It raised the chest pressure and checked the flow of blood in the great veins. Trumpet playing produced high chest pressures compared with other instruments, but it did not approach pressure levels induced by coughing. For orchestras with small working capital it might be possible to dispense with the assistant trumpeter if the first trumpeter wore a pilot's pressure suit, which could be surreptitiously inflated by a switch on the conductor's desk.

Reactions of Patients Told They Have Cancer.—Easson and Aitken-Swan (*British Medical Journal,* March 21, 1959) collated information from consultants who informed 231 selected patients (93 men and 138 women) that they had cancer and who recorded the comments of the patients. In the initial reaction 153 expressed approval that they had been told the truth, 44 denied that they had been told, 17 expressed disapproval, and 17 were noncommittal. Of 41 patients who were seen one to two and one-half years after the first interview 35 had not changed their views, 5 had, and 1 who initially denied that she had been told now talked freely of her condition as cancer. Of 37 who did not deny that they had cancer 26 did not mind others knowing, 10 had not let anyone know, and the attitude of 1 was not clear on this point.

There is no doubt that in Great Britain the word cancer connotes incurable disease with distressing and inevitable death. This fact must surely have its origin in experience, and only new experience rather than exhortation and reassurance will alter this conviction. It has long been British medical practice to conceal from patients the fact that they have cancer, with the consequence that the only diseases known as cancers were uncured or untreated ones. The cured cases were scrupulously labeled as something other than cancer. The effect of this "heads-I-win, tails-you-lose" policy is evident from the incredulity of patient's friends when told the truth. This general ignorance of the possibility of cure was also shown by an opinion survey in the Manchester area in 1954, when 64% of those interviewed did not know that cancer could be cured.

It would seem, therefore, to be an essential part of successful public education on cancer, and in the general interest, that some patients with the more curable types of growth should be told the diagnosis. By the same reasoning those already cured should likewise have the facts presented to them, but by then the effect is much less. If frankness of this sort could be shown, however, to have unexpected and undesirable sequelae, then such a policy would have to be abandoned, however worthy the motive for its continuance might appear. The contrary seems to have been established.

So far as can be discovered 67% of the group preferred to know what was wrong. This proportion, naturally, may measure only the success of the consultants' judgment in deciding whom to tell, but the fact remains that they seemed genuinely glad to know. In some cases telling the diagnosis had the effect of calming fears, the patient having interpreted silence or reassurance, while being referred to a hospital for cancer treatment, as meaning that his case was hopeless. Others felt that to know the truth helped them to fight better and gave them additional resources to call on, and they submitted to treatment in a different spirit and worried less.

In a different category were the 7% who claimed to have been upset by the knowledge of their diagnosis. Some of those who denied they were told may also come into this category. In some cases it was said that the frank use of "the word" was what shocked them, rather than fear that they had an incurable disease, which is itself indicative of an unhealthy state of public opinion. Some admitted that they would have preferred a lie. It must be remembered, too, that this small group of patients, however critical they may have been of the consultant's frankness, have probably had their cancers cured. Moreover, it seems likely that this figure will fall still lower than 7% as public experience grows and public opinion changes. It was concluded that, since most patients were able to accept the truth and benefit from the knowledge, all patients with the more curable cancers, unless obviously unstable, should be told their diagnosis. This is an essential part of public education on cancer, aiming at earlier treatment and higher rates of cure.

Maternity Hospital to Close.—Wiltshire mothers may soon be having their babies at a Royal Air Force station, because the Devizes Maternity Hospital is to close. Another, at Chippenham, is to be cut to one-half its bed capacity. An acute shortage of qualified midwives is the reason. Other small maternity units in different parts of the country have recently had to close or restrict admissions. Midwifery must be made more attractive if sufficient maternity beds are to become available. At present only about 20% of the nurses who qualify as midwives practice as such. Some hospital authorities have advocated a pay raise in the smaller country units, where the responsibility of the individual midwife may in any case be heavier as she has to work more on her own. Ministry of Health medical and nursing teams will soon be visiting some of the areas hardest hit. Their task will be to discover the reasons for the shortage of midwives, to advise on remedial action, and to make recommendations on which future policy can be based. Nursing staff leaders have told Ministry of Health and hospital authority representatives that their proposals for pay increases for 17,000 midwives and 50,000 student nurses were inadequate. More should also be done to improve the status of the midwife.

ANTIDOTE FOR PROCHLORPERAZINE INTOXICATION IN CHILDREN

To the Editor:—Many reports have appeared recently on the toxic manifestations of prochlorperazine (Compazine). It is a valuable tool in the symptomatic relief of vomiting in gastroenteritis and measles and in newborn infants. When it is used in appropriate dosage, based on weight, complications are rare. Few more alarming situations can occur than those which are seen in children with prochlorperazine toxicity. The signs, which have been well described elsewhere, include, briefly, an opisthotonic position, rolling up of the eyes, protrusion of the tongue, inability to speak or thick incoherent speech, and catatonic posturings.

In our experience these complications are not related to dosage. We have seen them occur after as little as one rectal dose on each of two successive days and, on the other extreme, after the ingestion of a large number of spansules. We have also noted a lack of toxic manifestations in infants and very young children. Our cases have occurred in the 4-to-10-year age group. Toxicity also has not been noted with use of large doses in otherwise healthy but disturbed children. Toxicity usually has occurred in the very ill child. The suggestion has been offered that an inflamed rectal mucosa enhances absorption of the suppository, but symptoms have been produced when the drug was given by mouth, and it may be that toxicity by rectal medication may be more common only because of the more common use of this route.

In seeking some way to help these children it has seemed that strong coffee administered orally has had some beneficial effect in early and mild cases. We gave caffeine and sodium benzoate intravenously, and the results of this treatment were encouraging. In each case the caffeine and sodium benzoate was given in a dose of 0.5 Gm. In a matter of 25 to 120 seconds each child responded in a dramatic fashion. Paraspinal muscular spasm, eye rolling, posturing, tremors, and confusion were entirely relieved. Two of these children were carried into the office in an agonizing position and in severe distress but were able to walk out unassisted a few minutes later. Symptoms did not return.

Caffeine and sodium benzoate seems to be an effective and rapidly acting antagonist to the toxic manifestations of prochlorperazine. The mechanism of its action is unknown, nor do we know the factors which predispose to toxicity.

Somerville, N. J.

RESPIRATOR TRACHEOTOMY TUBE

To the Editor:—A comment is in order regarding the article entitled "Respirator Tracheotomy Tube" in The Journal, March 21, 1959, page 136. The idea of devising ways to decrease leaks in the system is a good one and is at times highly desirable in respirator patients. Whether a tight fit is absolutely necessary depends on one's philosophy regarding the use of respirators and on the type of respirator unit being used.

A definite danger exists in the use of this type of tube-and-cuff arrangement. The basic idea is sound and has been used by many anesthetists to administer anesthetics and to ventilate patients on the wards, but unless the inflatable cuff is cemented to the metal tracheotomy tube there is the constant hazard that the cuff will slip off and obstruct the patient's airway. Unless this situation is diagnosed quickly and the cuff withdrawn the obstruction may be sufficient to result in death. This danger is made more real in the patient being ventilated by a respirator, due to the constant motion of the tube with each cycle. In the presence of tracheal secretions, even a tight fitting cuff will tend to slide on the metal tube. Rubber cement has been used with success to prevent this. As an additional safeguard in these patients, the inflation tube to the cuff is pulled taut and clamped to the umbilical tape which holds the tracheotomy tube in place. This tends to result in the cuff riding upward rather than off the end. The cuff should be inflated with only enough air to prevent a leak around the tracheotomy tube. It is felt (and without documented evidence) that these cuffs should be deflated for a few minutes every four or five hours to prevent any damage that might result from pressure against the mucosa.

Regarding tracheotomy tubes in general for respirator patients, it seems desirable to use one made of a plastic which would soften at body temperature. This would allow the tube to conform more to the anatomic course of the trachea than do some of the standard metal tracheotomy tubes. For patients breathing on their own, this probably is not a critical factor, but the tube in a respirator patient is in a continual back and forth motion, and if the end impinges on or rubs the tracheal wall an ulceration will result in time. This has been observed, with ulcerations at the cord level, when rubber endotracheal tubes are used.

MEDICOLEGAL ABSTRACTS

Zoning Restrictions: Right of Physician to Maintain Office in Private Residence.—This was an action to restrain the defendant physician from erecting a combined home and office structure in an area zoned for single family dwellings. The trial court denied the injunction and the plaintiffs appealed to the court of appeals of Ohio.

The defendant, 10 years prior to this suit, had purchased a piece of property which was subject to a restriction that the property "shall be used for (1) resident purposes only and (2) not for any purpose of business or trade." This property was also located in an area zoned for single family residences. After the defendant had completed plans for the erection of a combination residence and office on this location, he learned that some of the nearby residents objected to the building. Although he had been told that no rezoning would be necessary, he applied to the planning commission for a change from single family residential to commercial. This was denied. He then applied for a building permit and this was also denied. The defendant was then advised by the planning commission to take his problem to the board of zoning adjustments. After a hearing before this board, the building inspector's opinion was reversed and a building permit issued. The plaintiffs then took the case to the common pleas court, where an injunction was denied.

On appeal, the plaintiffs contended the defendant was violating both the building restriction and the zoning provisions. So far as the building restriction was concerned, the court of appeals pointed out that the restriction was as to the use of the property. As long as the building was used for residential purposes only there was no restriction preventing its erection. Furthermore, the court pointed out that the restriction itself had been created to run for 35 years and that this period would expire even before the building would be completed.

The zoning ordinance referring to single family residence areas permitted certain accessory uses of property therein so long as the residential character of the property was not infringed. Among other things the ordinance provided: "The office of an architect, attorney, clergyman, dentist, engineer, physician, surgeon or other professional person may be located in a residence or an apartment used by such person as his private residence."

After a consideration of all the evidence relative to the type and character of the proposed building and the use to which the defendant intended to put it, together with the character of the surrounding and adjoining property, the court of appeals was of the opinion that no rezoning was necessary and that the defendant was entitled to erect the building and use it for a combination residence and office. The court also held that the practice of medicine was not to be classed as a trade or business.

The plaintiffs' request for an injunction to restrain the use sought by the defendant was therefore denied. *Diebel v. Wilson,* 150 N. E. (2) 448 (Ohio, 1957).

Libel and Slander: Qualified Privilege.—This was an action for damages for libel and slander against the Health Insurance Plan of Greater New York and its medical director and deputy medical director. The defendant's motion for summary judgment was heard in the Supreme Court, special term, Kings County, New York.

The defendant HIP is a nonprofit medical expense indemnity corporation. Each of the 500,000 insurees of this corporation is given a directory listing the various medical groups which will furnish services for the members and listing the names and addresses of the general practitioners and specialists affiliated with each group. The insuree selects the medical group which is to provide him with medical care. The plaintiff was a director and co-chief of surgery of one of these groups.

In 1953 the two individual defendants were informed that the plaintiff's malpractice insurance was not being renewed for cause. They made an investigation which indicated that the malpractice insurance company had paid some losses on some operations which this plaintiff had performed. Conferences were held at which minutes were recorded. The defendants maintained that they considered not only this question of malpractice insurance but also the opinion of the chief surgeon in one of the hospitals with which the plaintiff was connected and certain changes in his status on the staff of a hospital about which they claimed he made misrepresentations. It was at these conferences and hearings that the defamations complained of were made. The plaintiff avers that, generally speaking, the defamatory statements charge that he is professionally incompetent in his specialty; that appointments at hospitals were not renewed because of incompetency; that he does not possess the minimal hospital requirements of HIP; that he lacks training and skill; and that he deliberately concealed and withheld from the defendant HIP information as to his background, affiliations, and employments.

The plaintiff then went on to allege that the defendants were motivated throughout the hearings by actual malice and that the hearings were "designed to rubber-stamp a pre-determination of the individual defendants to effect his removal from the medical group of which plaintiff was a director and co-chief of surgery." To support this contention he recited some controversy and difficulties he had had with the malpractice defense board of the New York State Medical Society over the purchase of insurance.

On the record, said the court, the defense of qualified privilege was properly interposed and established prima facie. Such a privilege, however, may be destroyed by a showing of excessive publication or malice. Here, said the court, the plaintiff presented a triable issue of fact with respect to the existence of actual malice. The defendants' motion for a summary judgment was therefore denied. *Anonymous v. Health Insurance Plan of Greater New York, et al.,* 173 N. Y. S. (2) 74 (N. Y., 1958).

Malpractice: Suturing Nerve to Tendon.—This was an action for damages resulting from the alleged negligence of the defendant physician. From a judgment in favor of the plaintiff the defendant appealed to the Supreme Judicial Court of Massachusetts.

The patient, 15 years of age, had pushed her left hand through two panes of glass and suffered a laceration of her left wrist and flexor tendons. She was taken to a hospital where the defendant operated on her left wrist. The operative report showed that all the superficial tendons, except the flexor tendon to the little finger, had been severed. The deep tendons were intact. Presumably, the upper band of the severed tendon was isolated and brought down and sutured to the remainder. The skin was then closed and the plaintiff's hand was in a plaster cast and Ace bandages for several weeks. When the cast was removed she went to a hospital for physiotherapy, and it was then discovered that there was a loss of median nerve function. In a subsequent exploratory operation it was found that the proximal segment of the median nerve had been sutured to the distal portion of the superficial tendon going to the middle finger. The distal end of the median nerve was found lying free. A proper repair was done but the plaintiff continued to have a sensory loss at the base of her palm and a neuroma in her left wrist.

A medical expert who testified for the plaintiff said that the median nerve is approximately the same size as the superficial tendon, but its color is slightly different. The texture of the superficial tendon is more firm than that of the median nerve, which may be compressed with the fingers. Anatomically the median nerve is not at any time connected with the superficial tendon. In the opinion of this expert if the median nerve had been completely sutured instead of leaving one end lying loose in the wound, and if one end of the median nerve had not been sutured to the superficial tendon, the probabilities are that the plaintiff would have obtained a better result from the operation and would not have suffered a neuroma and sensory loss.

We are of the opinion, said the court, that the jury could warrantably find that the defendant was negligent in not distinguishing the superficial tendon from the median nerve, that the operation was not done with the care and skill generally used and possessed in the community, and that a surgeon who undertakes to operate in a field wherein nerves and tendons are exposed will distinguish them and not unite a nerve with a tendon.

The judgment in favor of the plaintiff was accordingly affirmed. *Fitzgerald v. Leach,* 150 N. E. (2) 12 (Mass., 1958).

MEDICAL FILM REVIEWS

Block Dissection and Pneumonectomy for Bronchogenic Carcinoma, Right Side: 16 mm., color, silent, showing time 21 minutes. Prepared by John F. Higginson, M.D., Portland, Ore. Produced by and procurable on loan from Veterans Administration, Central Office Film Library, Washington 25, D. C.

This film shows the surgical technique of right-sided en bloc dissection and pneumonectomy for bronchogenic carcinoma. Preoperative and postoperative chest x-rays are shown as well as the specimen immediately after surgery. Dissection from the cupola of the chest to the diaphragm is shown in steps. Partial resection of the pericardium is demonstrated as part of the block dissection. This is a well-done film of an accepted operation performed in an acceptable technique, although it is believed that this particular operation is now less popular than it was a few years ago. This fact, however, does not detract from the great value of this film, which, with its opposite number by the same author of a radical left-sided pneumonectomy, makes a perfect lesson for one wishing to study or learn the technique of this operation for either right or left side. The surgical technique and photography are excellent. It is most suitable for showing to surgeons, particularly thoracic surgeons and surgical residents interested in thoracic surgery.

Fascial Transplantation for Paralyses of the Abdominal Wall: 16 mm., color, sound, showing time 11 minutes. Produced in 1958 by Billy Burke Productions, Hollywood, for C. L. Lowman, M.D., Los Angeles. Procurable on loan from E. R. Squibb and Sons, 745 Fifth Ave., New York 22.

This excellent motion picture describes and illustrates the indications and technique for fascial transplantation in paralysis of the abdominal muscles. The procedure was originated by the author. Several patients with paralysis of the abdominal muscles after poliomyelitis are demonstrated before and after the operation. The film shows the importance of the abdominal muscles as a link joining the pelvis and thorax and the part played by these muscles in coordination of movement of the upper and lower halves of the body. The effect of paralysis of the abdominal muscles on the cardiovascular, respiratory, and gastrointestinal systems is discussed. The technique of the operation is shown by drawings and by an operation on a patient and a cadaver. Postoperative physical therapy and end-results are shown. The photography is excellent. The film should be of particular value to the orthopedist and to those in branches of medicine concerned with paralytic disease.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Abdominal Epilepsy. E. Brandrup. Nord. med. 61:59-61 (Jan. 8) 1959 (In Danish) [Stockholm].

Attention is called to abdominal epilepsy as a diagnostic possibility in cases of recurrent acute abdominal pain. Two cases from the neurological department in Odense, in a boy, aged 3½ years, and a woman, aged 44, respectively, diagnosed as abdominal epilepsy, are described. Abdominal (or intestinal) epilepsy is diagnosed when abdominal pain is the only, or the most important, manifestation of an attack in epilepsy. The pain is paroxysmal in kind, sets in suddenly and terminates as suddenly, and the picture is reproduced with stereoptic uniformity time and again. In many patients the pain is accompanied by nausea and vomiting. The disease seems to occur more often in children than in adults. Electroencephalography is a valuable aid in diagnosis. An important point in diagnosis is that the patient reacts to antiepileptic treatment.

Rheumatic Heart Disease Associated with Atrial Septal Defect: Clinical and Pathologic Study of 12 Cases of Lutembacher's Syndrome. J. Espino-Vela. Am. Heart J. 57:185-202 (Feb.) 1959 [St. Louis].

This paper deals with 12 patients who had mitral valvular damage in association with wide atrial septal defect (Lutembacher's syndrome). Embryologically, the defect seems to be the result of extensive resorption of the septum primum with faulty development of the septum secundum. Three of the patients had virtually a single auricle. Although other patients were observed who had the characteristic clinical syndrome, the author limited this report to the 11 cases proved at autopsy and the 1 proved at operation. This seems a relatively high number, and yet it is rather surprising that more cases are not seen, since rheumatic heart disease is responsible for 40% of the admissions to the National Institute of Cardiology in Mexico and since the second most frequent congenital cardiac anomaly is atrial septal defect. Thus, it seems strange not to see these 2 entities associated more often. The ages of the 12 patients ranged from 10 to 71 years. There were 8 females and 4 males.

Clinically, the disease was most frequently typical of severe rheumatic heart disease. The clinical features suggestive of the association of rheumatic valvular disease and atrial septal defect were: (1) atypical auscultatory findings of rheumatic mitral stenosis: no presystolic accentuation of the diastolic rumble; (2) the presence of a systolic murmur accompanied by a palpable thrill in the pulmonary area; and (3) cyanosis of slight to moderate degree (not seen in the absence of heart failure). Supportive roentgenologic evidence of this association were the large size of the pulmonary main trunk and its branches, with vigorous pulsations, in association with a mitral or mitral-tricuspid cardiac contour, and slight or absent left auricular enlargement. Finally, electrocardiographic data suggestive of this diagnosis were the presence of right bundle-branch block and commonly qR-type complexes in lead V_1 with concomitant left auricular enlargement ("mitral" P waves).

In only 3 patients was the diagnosis of atrial septal defect readily apparent, while that of rheumatic heart disease was not so obvious. In 2 patients neither one of the 2 conditions was correctly postulated. One of these patients had aortic coarctation, and the other had lived to the age of 71 years with cardiosclerosis and chronic cor pulmonale.

The Treatment of Cardiac Arrest Following Myocardial Infarction. J. G. McGregor and D. E. Newton. U. S. Armed Forces M. J. 10:125-140 (Feb.) 1959 [Washington, D. C.].

Resuscitation was attempted in 5 patients with cardiac arrest secondary to myocardial infarction in Brooke Army Hospital, Fort Sam Houston, San Antonio, Texas. In cardiac resuscitation it is imperative that cardiac compression and pulmonary insufflation be instituted within 4 minutes after cardiac arrest. In the first patient, a 51-year-old man, the resuscitation by thoracotomy, cardiac massage, and electric defibrillation was successful, because it was instituted at the first sign of ventricular fibrillation. This constitutes the 4th reported instance of successful resuscitation of a patient who sustained ventricular fibrillation secondary to myocardial infarction. It is of interest that the only drug used in this patient was procainamide hydrochloride; it was not given during

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

the actual resuscitation, but only specifically to prevent the premature beats following defibrillation. This patient is well, except for a moderate angina pectoris. The second patient, a 31-year-old man, died one hour after resuscitation from damage of the central nervous system, probably due to the unnecessary delay in instituting cardiac resuscitation. In the remaining 3 patients the attempt at resuscitation was unsuccessful, because too much valuable time had been lost between cardiac arrest and application of resuscitative measures.

The measures necessary for resuscitation of patients with ventricular fibrillation are not applicable to all patients or to all situations. The condition of the patient should be evaluated; the occurrence of previous myocardial infarctions, the presence of severe systemic disease, the age of the patient, and the minutes elapsed after cardiac arrest should be considered before attempting cardiac resuscitation.

Pulseless Disease (Takayashu's Syndrome). S. S. Misra and S. Prakash. Am. Heart J. 57:177-184 (Feb.) 1959 [St. Louis].

A peculiar syndrome, characterized by absence of pulsations in the carotid and radial arteries, is met with in aortic arch syndromes such as syphilitic aneurysms, rarely in dissecting aneurysms, and also in traumatic injuries of the chest. There is a group of patients in whom there is a primary panarteritis of unknown etiology, and this has been variously described as Takayashu's syndrome or pulseless disease. It is a rare syndrome affecting chiefly young women; hence, it has also been called "young female arteritis." The authors present 3 patients with this rare disease. The first patient, an 18-year-old male Hindu, complained of enlargement of cervical lymph nodes for the last 6 months, anasarca, giddiness, and general weakness for 3 months before admission. Radial, brachial, and carotid pulses were absent on both sides. The patient died, and on autopsy the aorta showed evidence of panarteritis of undetermined etiology. Generalized amyloidosis might have been due to the chronic suppurative cervical lymphadenitis, and the nephrotic syndrome was secondary to the renal amyloidosis. Whether or not there was any correlation between amyloidosis and pulseless disease is difficult to say.

The second patient was a 15-year-old Hindu girl, the youngest patient ever reported to have pulseless disease. Her clinical picture resembled that of the first patient in many respects. In addition to the pulseless condition, she also had cervical lymphadenopathy, which proved to be due to caseating tuberculous adenitis, and a nephrotic syndrome secondary to amyloidosis, which might have been secondary to the caseating tuberculous lymph nodes. The third patient was a 54-year-old Hindu woman, who had chronic progressive obliterative involvement of the radial arteries. A bilateral immature cataract was probably due to the deficient blood supply. Giddiness and numbness and tingling in the left upper limb might be explained as being due to chronic ischemia of the brachiocephalic arteries.

In the first patient no etiological factor could be determined for the panarteritis which resulted in pulseless disease. The second patient had caseating tuberculous cervical adenitis and a strongly positive tuberculin test, which might suggest a tuberculous etiology of the arteritis, as was suggested by Japanese authors. In the third patient an elevated serum cholesterol level and the fact that biopsy of the radial artery showed some atherosclerosis suggested much more advanced atheromatosis in the aorta resulting in obliteration of the pulse. A direct histological examination of the aorta was not possible in the 2 patients who are still alive. Peripheral arterial diseases were excluded in all 3 of the patients by biopsy of the radial artery. A nephrotic syndrome due to amyloidosis, as observed in the first 2 of these 3 patients, has never before been reported in association with pulseless disease.

"Pulseless Disease": Review and Report of Case of Takayashu's Syndrome. J. Fossgreen. Ugesk. læger 121:45-49 (Jan. 8) 1959 (In Danish) [Copenhagen].

The absence of pulse in the cranial part of the body, due to abnormal changes in the great vascular branches originating from the aortic arch, is a symptom which has long been known. More than 100 cases of Takayashu's syndrome or pulseless disease have been published. The disease almost exclusively affects young and middle-aged women. An arteritis is localized to the aorta and the great vessels which leave the aortic arch. The process involves all vascular layers and gradually leads to the obliteration of the lumens of the great branches. The history often reports rheumatic or other infections, and periods of fever are a frequent symptom. The fully developed Takayashu's syndrome is characterized by the absence of pulse in the upper part of the body, trophic changes in the cranium, cerebral symptoms, eye changes, carotid sinus syncope, cardiac symptoms, and development of a collateral circulation; laboratory findings show constantly increased sedimentation reaction. Takayashu's syndrome should be included in differential diagnostic considerations in case of neurological phenomena or disturbances in vision in younger women, especially if the symptoms are vague. Careful palpation of the arteries of the head and arms will give the correct diagnosis. The prognosis is unfavorable. If, however, there is only closure of the subclavian arteries, the outlook can be more optimistic. The patients live between 1 and 20 years after onset of the symptoms. Death is usually due to ischemic brain lesions. No causal therapy is known. Cortisone or prednisone may possibly prevent progression of the inflammatory process. The patient should avoid overexertion, and frequent periods of rest are advantageous. Carotid sinus syncope can be treated with atropine or irradiation of the carotid sinus. Antibiotics are without effect. Detailed report is given of the case of a woman, aged 32 years.

The Diagnosis of Thyroid Disease in Private Practice. J. Marks and R. L. Fulton. Ohio M. J. 55:186-190 (Feb.) 1959 [Columbus].

The authors studied 230 patients in order to ascertain to what extent the 24-hour radio iodine (I^{131}) uptake determination was correlated with the clinical diagnoses of the patients. Determinations of basal metabolic rates and serum cholesterol levels, being available in many of the observed patients, were similarly analyzed. Of the 230 patients, the condition of 174 was diagnosed as euthyroid, of 45 as hypothyroid, and of 11 as hyperthyroid. Of the latter group, 7 patients had Graves's disease, and 4 had toxic nodules. Data indicate that the 24-hour I^{131} uptake determination has a high degree of correspondence with clinical thyroid diagnoses and should be employed whenever possible in helping to establish the status of the thyroid gland. Determination of the basal metabolic rate has been used for many years in the evaluation of thyroid gland function; these studies further established this test as a worthwhile procedure in the study of the thyroid gland. The serum cholesterol determinations performed in this series were inconstant and of questionable value in evaluating the function of the thyroid gland.

While the I^{131} uptake and the basal metabolic rate determinations are helpful tests, they impose a challenge on the clinician in many borderline patients with hypothyroidism and hyperthyroidism. The practicing physician is obliged to hold to his clinical impression at times when the imposing documentation of the scintillation counter or the oxygen consumption curve is at variance with his judgment. The authors believe that neither the 24-hour I^{131} uptake test nor the basal metabolic rate are clearly diagnostic in many borderline cases and that, even after an entire "battery" of tests have been performed, the clinician must still come to a conclusion on clinical grounds.

Intrahepatic Cholestasis. C. M. Leevy. Am. J. Surg. 97:132-136 (Feb.) 1959 [New York].

"Intrahepatic cholestasis," a descriptive term proposed for obstruction to bile outflow incident to a pathological process which originates within the liver (J. A. M. A. 150:1367-1372 [Dec. 6] 1952), may be produced by a variety of medical diseases. According to the initiating clinicopathological process, the author classified his patients with intrahepatic cholestasis into 3 groups, namely, those with functional cholangiolar disease, those with neonatal hepatitis, and those with interlobular bile duct degeneration and atresia. The course in 22 patients with protracted jaundice due to functional cholangiolar disease is described. Bile stasis without morphologic alteration of the parenchymal cell or biliary network occurred during the course of viral hepatitis in 5 of the 22 patients and after the administration of various drugs, such as chlorpromazine, methimazole, methyltestosterone, arsenicals, and sulfonamides, to 17. Usually jaundice rapidly subsided, and complete recovery occurred in 18 of the 22 patients. Jaundice persisted in 4 patients, and subsequent studies showed portal fibrosis in 1 and biliary cirrhosis in 3.

Unfortunately in many patients it is not possible to distinguish intrahepatic cholestasis clearly from extrahepatic biliary obstruction which requires surgical therapy. The history, biochemical liver function tests, liver biopsy, and special laboratory procedures may be helpful in individual patients. Early operative exploration with biopsy and cholangiography is often desirable to eliminate the possibility of an extrahepatic obstruction in patients with progressive jaundice attributed to functional cholangiolar disease, neonatal hepatitis, and atresia of the interlobular bile duct. Surgical intervention in these conditions is poorly tolerated, and an attempt should be made to minimize surgical trauma.

Incidence of Gall Bladder Disease in "Normal" Men. R. S. Wilbur and R. J. Bolt. Gastroenterology 36:251-255 (Feb.) 1959 [Baltimore].

Routine cholecystograms on 1,233 male executives, with an average age of 46.8 years, were performed at the University Hospital in Ann Arbor, Mich., during the last 10 years. These studies on active men in the prime of life have revealed a higher than expected incidence of roentgenologically shown biliary dysfunction. Of these 1,233 "normal" men, 182 showed some evidence of gallbladder abnormality past or present, although they averaged less than 50 years of age. Of these 182 men, 92 had visible stones, 25 had had their gallbladders removed, 20 demonstrated definite evidence of gallbladder disease manifested by nonvisualization of the gallbladder, and 45 exhibited faint visualization of the gallbladder. Of the 92 men with visible stones, 59 were completely asymptomatic; of the remaining 33, two-thirds had only the unreliable symptoms of dyspepsia and epigastric pain. These same symptoms occurred in 43 men out of a group of 488 in whom no organic disease was demonstrable in the gallbladder or elsewhere. It is also interesting to note that 6 of 16 men, previously subjected to cholecystectomy and with no other cause for symptoms, still had indigestion and epigastric pain. Typical "biliary colic" had occurred in only 3 men with visible stones and in 4 men out of the group of 488 with normal cholecystograms.

Even if the incidence rate of gallbladder dysfunction among employed men throughout the United States were a good deal lower than that in this series, the number of active American men with asymptomatic gallstones must be in the millions. The fact that the incidence of gallstones in men rises sharply after the retirement age is reached and that the percentage in women is significantly higher than that in men until the 7th decade clearly illustrates the magnitude of the problem of the "silent gallstone." The authors think that cholecystectomy, in the absence of true biliary colic or jaundice, should not be performed in the hope of relieving vague indigestion or dyspepsia, just because the cholecystogram demonstrates stones.

Intestinal Polyposis Associated with Melanin Spots: Peutz-Jeghers Syndrome. J. Guillard, R. Laumonier, J. Seyer and R. Boulet. Presse méd. 66:2076-2079 (Dec. 25) 1958 (In French) [Paris].

The hereditary nature of intestinal polyposis associated with melanin spots was observed in 10 members belonging to 3 generations of a family. The father of the first generation died, at the age of 56 years, of occlusion of the small intestine, which was attributed to periodic mild episodes of abdominal occlusions. One of the 2 sons in the second generation, at the age of 46 years, had a true Peutz-Jeghers syndrome. Melanin spots were noted on the interior side of the left cheek, on the cornea, and around the eye. Multiple polyps were present in the stomach, and one in the ileum. The patient had had periodic abdominal pain for 6 years, which had intensified recently. Of his 5 children (third generation), the eldest daughter, 19 years of age, who was the starting point of this genealogical investigation, had a true Peutz-Jeghers syndrome. A 17-year-old son had diffuse melanin spots of the oral mucosa and lips, and another son died, at the age of 8 years, of an ileoileal invagination.

Both father and daughter were operated on for multiple polyposis and had a satisfactory recovery. The daughter had had intense abdominal pain related to occlusion, which had been accompanied by vomiting for 3 years before the operation. She had polyps in the stomach, and there was a double invagination of, and several polyps in, the jejunum. Microscopic examination of the specimens obtained by aspiration biopsy of the stomach in both patients revealed proliferation of benign polyps, accompanied by retrogression of the mucosa of the fundus of the stomach. The histophotometric test disclosed that polyps in both patients were benign lesions, exhibiting mild nuclear activity.

Pernicious Anemia: A Disease of the Senile and Presenile Ages. G. Benedetti and P. Ulivieri. Gior. gerontol. 6:965-970 (Dec.) 1958 (In Italian) [Florence, Italy].

Recent statistical studies show that pernicious anemia, up to recent times considered a disease of middle age, is frequent in people of the senile and presenile age groups. Pernicious anemia, at least in its beginning phase, is a disease of the digestive apparatus, and the study of its occurrence in senile patients may be revealing insofar as these patients are more liable to suffer episodes of protein and vitamin deficiency as well as alterations of the gastrointestinal functions. The authors observed 11 patients, 52 to 77 years of age, with pernicious anemia and report on the clinical symptoms and on the treatment followed in curing these patients. Sex did not account for any substantial difference in the frequency of the disease and in the clinical manifestations. Most of the patients presented clear signs of bone marrow hypoplasia, and the patients most advanced in age had almost an aplasia. "Associated" or "masked" pernicious anemia was present in most of the patients, who presented also a cardiocirculatory decompensation syndrome. The study of gastric secretion showed that all patients, except one, showed signs of histamine-resistant achylia. Disturbances of the glandular system, mainly hypothyroidism, were present in the patients most advanced in age, and especially in those who had not responded to hepatotherapy.

Half of the patients most advanced in age before the occurrence of the symptoms of anemia had been treated with antibiotics, given in large doses and for long periods of time, on account of pneumonia, bronchitis, or bronchiectasis. In these patients hepatotherapy and vitamin B_{12} had had no effect, and the patients were subjected to blood transfusions of 100 to 150 cc. each time. The amount of blood given at each transfusion was kept low in order not to overcharge the circulation, since most of the patients had cardiac decompensation. The blood transfusions had a good and immediately stimulating effect—the appetite returned, atrophic manifestations of the tongue and gastrointestinal disturbances disappeared, and the condition of the bone marrow improved. The transfusions were always combined with vitamin B_{12} given parenterally, iron preparations given by mouth or intravenously, vitamin B complex, vitamin B_4, and large doses of cocarboxylase given intravenously. The results obtained with this therapy were good in most of the patients and were very good in the remainder.

SURGERY

Clinical and Statistical Considerations on 1,000 Cases of Malignant Tumors of the Breast.

F. de Bernardis. Acta chir. italica 14:647-684 (Sept.-Oct.) 1958 (In Italian) [Padua, Italy].

A clinical and statistical study on 1,000 patients with malignant tumors of the breast observed in the surgery clinic of the University of Padua from November, 1939, to December, 1956, is presented. Eleven patients were male, and the others were female; most of them were in the 5th or 6th decade of life. Epithelial tumor, especially pure adenocarcinoma, was the most frequent form observed. The tumor was still in the first or second stage in most of the patients. Eighty-one women had undergone previous operation for benign tumor of the breast. In 48 patients a definite relationship between the tumor and a trauma in the genital system was found. Metastasis was present in 56% of the patients operated on. Roentgenotherapy was beneficial, especially when used immediately after radical operation.

The general therapeutic procedure was as follows: Early radical mastectomy (Halsted technique) was performed whenever possible; at least one cycle of roentgenotherapy was given as soon as the operative wound had healed; large doses of androgen hormones were administered to the patients who presented metastasis even if the metastasis was localized or if it had been removed surgically. Patients on whom it was not possible to operate were given roentgenotherapy as soon as possible and were injected with large doses of cytostatic, chemotherapeutic, antineoplastic substances; adrenalectomy and hypophysectomy were performed when acceptable to the patients. The results of the treatment could be followed in 980 patients. Two years after the initial treatment 70% of the patients were still alive, and 5 years after 42% were alive. Later observations showed that 39% of the patients were still alive, but 61% had died.

The Direct Risk of Cholecystectomy: Analysis of 1,458 Operations.

M. W. van Weel. Nederl. tijdschr. geneesk. 103:6-11 (Jan. 3) 1959 (In Dutch) [Amsterdam].

The author cites evidence indicating that it is erroneous to believe that cholelithiasis which causes no symptoms is "innocent." Any gallstone condition is potentially dangerous, so that, if it were not for the risk of the operation, it would be advisable to remove the gallbladder whenever there is a definite diagnosis of gallstones. To ascertain the risk, the author analyzed a total of 1,458 gallbladder operations, of which 1,217 were interval operations and 241 were "hot" cholecystectomies, that is, they were performed during acute cholecystitis. Interval operations were performed on 987 women and on 230 men, the ratio of women to men being 4.3:1; operations during the acute stage, however, were performed on 171 women and on 70 men (ratio of 2.2:1). The majority of patients in both groups were over 50 years of age, but whereas interval operations were most frequent in patients between 50 and 59 years, operations for acute cholecystitis were most frequent among those between 60 and 69 years of age.

A tabulation of findings during interval operations shows that cholelithiasis without infection existed in 49.8% of the women and in 26.1% of the men and cholecystitis with stones in 48.4% of the women and in 70% of the men. The choledochus was explored in 53.4% of the women and in 63% of the men; and stones were found during choledochal exploration in 38.4% of the women and in 57.3% of the men. There was no great difference between the sexes with regard to the incidence of pancreatitis and carcinoma of the gallbladder. Complications were somewhat more frequent and more severe after operations during acute processes than after interval operations. The surgical mortality has been reduced to very low levels, being 0.25 and 2.5%, respectively, for 1,217 interval operations and 241 "hot" operations. Thorough diagnostic studies and careful selection of patients are important. Furthermore, the operation should be performed at the earliest possible stage of the disease. In patients with acute cholecystitis the author recommends immediate cholecystectomy.

Iliofemoropopliteal Arterial Reconstructions for Arteriosclerosis Obliterans: Factors Influencing Late Patency.

R. Warren and J. L. Villavicencio. New England J. Med. 260:255-263 (Feb. 5) 1959 [Boston].

The authors report on 70 patients with obliterative arteriosclerosis, on whom iliofemoropopliteal arterial reconstructions were performed at the West Roxbury Veterans Administration Hospital and the Peter Bent Brigham Hospital in Boston between 1953 and 1956. The upper ends of the arterial reconstructions were below the origin of the external iliac artery. Three different methods of reconstruction were employed, namely, arterial homografts in 36 patients, venous autografts in 13, and thromboendarterectomy in 21. The incidence of patency for at least one year after the operation was 9% for arterial homografts, 18% for venous autografts, and 55% for thromboendarterectomy. The best results in this series and the best results that have been reported to date by other workers, in terms of long-term patency of reconstructed iliofemoral segments, have been those of thromboendarterectomized segments; these were operated on by the intraluminal stripping technique, and the patients were discharged from the hospital with the circulation restored.

Roentgenologic studies and pathological studies by biopsy of reconstructed segments or by amputation showed that the thromboendarterectomized segments underwent a marked reaction of fibrosis during the first 6 months after the surgical intervention. If they survived this period, further reaction did not take place, and relative long-term patency could be expected. In the venous autografts, a similar susceptibility was observed during the first 6 months after the surgical intervention, presumably resulting from a variety of factors, such as constriction of anastomosis, irregularity of the segment itself, taut adventitial bands, and external hematomas. If the grafts did not close because of these factors in the first 6 months, relative long-term patency could be expected. Progressive lesions occurred postoperatively in 50% of the arterial reconstructions performed with the aid of arterial homografts. These lesions consisted of mural thrombus, rapid degeneration with calcification, aneurysm, and late degeneration similar to that resulting from arteriosclerosis. Later closures occurred in these segments, and in others that showed no lesions, to the extent that no security against closure was gained with the passage of time.

There was no relation of the level of serum cholesterol or the incidence of other obliterative arteriosclerotic lesions to the lesions occurring in the reconstructed segments or the incidence of closure of reconstructions. Twenty per cent of the extremities in which closure of the arterial reconstructions occurred became worse, and of these about 50% required amputation, which probably would not have been necessary if the reconstruction had not been attempted. It is emphasized that the implications concerning long-term patency drawn from this study of arterial reconstructions, the upper ends of which were situated not higher than the external iliac artery, are not applicable to reconstructions of the aorta and common iliac arteries, which have a higher incidence of late patency.

Dermoid and Epidermoid Tumors in the Central Nervous System of Adults. C. S. MacCarty, M. E. Leavens, J. G. Love and J. W. Kernohan. Surg. Gynec. & Obst. 108:191-198 (Feb.) 1959 [Chicago].

The authors reviewed the records of patients with epidermoid and dermoid tumors of the central nervous system observed at the Mayo Clinic up to and including 1955. They define epidermoid tumors as neoplasms of congenital origin comprised of the outer layer of the epidermis, squamous epithelium, and desquamated epithelium—and occasionally an outer layer of fibrous and connective tissue. The stratified squamous epithelial layer contains keratohyaline granules. Dermoid tumors are teratomas composed primarily of skin and its derivatives. They differ from the more complex teratomas, which usually contain residues of tissue representing all 3 germ layers. Both epidermoid and dermoid tumors are considered to be congenital in origin. The dermoid tumors are the most frequently seen in conjunction with a dermal sinus except in adults and appear symptomatically earlier in life than the epidermoid tumors.

The total of 77 patients included 45 with epidermoid and 32 with dermoid tumors, but this report is concerned chiefly with the 63 adult patients (over 15 years of age), 44 of whom had epidermoid and 19 dermoid tumors. Of the 44 epidermoid tumors, 24 were located intracranially, 14 in the skull, 3 encroached on the orbit as well as extending intracranially, and 3 were intraspinal in location. Twenty-one of 24 intracranial epidermoid tumors were treated surgically; 11 were removed completely, 8 were incompletely removed, and in 2 it was not known whether removal was complete or incomplete. There were 4 hospital deaths. Of the 17 patients who survived operation, 1 died in 4 months. Follow-up data on 8 patients an average of 7.3 years after operation show that 2 have recurrences and 6 do not. The 14 intradiploic epidermoid tumors were removed without a death, and only 1 tumor recurred. Three intraorbital tumors were successfully removed. The 3 adult patients with spinal epidermoid tumors survived.

The 19 dermoid tumors were located as follows: intracranial (9), intradiploic (4), intraorbital (1), and intraspinal (5). Six of the 9 intracranial dermoid tumors were supratentorial. All 6 patients with supratentorial tumors were operated on, but the tumor of only 1 was removed completely. The latter patient was alive 18 years and 5 months later, but was still having occasional seizures. There were 2 hospital deaths in the group. One patient was alive and well 7 years after incomplete resection of the tumor. Another was alive and well 16 years after operation. The 6th patient was not traced. All 3 patients with infratentorial tumors were successfully operated on and are alive without recurrences. The 4 adults with intradiploic dermoid tumors had their tumors successfully removed. In the one patient with an intraorbital dermoid tumor, the tumor was removed except for a small piece of capsule attached to the globe. The patient had survived 5 years and 10 months at time of follow-up examination. Of 5 patients with intraspinal dermoid tumors, 3 had intradural intramedullary tumors of the conus and filum; 1 had an intradural extramedullary tumor of the cauda equina; 1 had a low lumbar caudal tumor with a spina bifida. Of the 3 patients with intramedullary tumors of the conus, 1 had complete removal of the tumor and 2 had incomplete removal. One patient with an intradural extramedullary tumor of the cauda equina had complete removal with sacrifice of adherent nerve roots. One patient had a dermoid tumor weighing 670 Gm. and associated spina bifida occulta; this dermoid was completely removed. In patients with intramedullary conus lesions, the postoperative management of functions of bladder and intestine presented difficulties.

Congenital anomalies were associated with 3 of the epidermoid tumors and with 50% of the dermoid tumors. These anomalies included anomalous fusion of vertebrae, cyst of the septum pellucidum, presence of dermal sinuses, harelip, pilonidal sinus, cysts under the occipital portion of the scalp at birth, cervical rib, meningocele, and spina bifida. A surprising number of patients with both groups of tumors involving the intracranial, intraorbital, or intradiploic areas had mental symptoms. There were 4 operative deaths in 41 patients with epidermoid tumors and 3 operative deaths in 32 patients with dermoid tumors. Long survival may occur in these cases, even though the tumor is incompletely removed.

Prednisone in Chronic Lymphoedema of the Legs. J. Calnan and S. C. Truelove. Brit. J. Plast. Surg. 11:329-334 (Jan.) 1959 [Edinburgh].

Chronic edema of the legs, when not due to cardiac or renal disease, may be due to one of several causes. In tropical elephantiasis, the lymphatics are blocked by Filaria bancrofti. In tuberculosis, an analogous blocking of lymphatic drainage may occur through scarring. A large venous thrombosis may leave a chronic lymphedema as one of its sequels. A carcinoma may infiltrate the main lymphatics of a limb. Deep x-ray therapy may cause fibrosis which, in turn, produces lymphatic obstruction. In some patients the condition follows accidental trauma or surgery. Yet, when all these known causes are excluded, there remain many patients with chronic lymphedema of the legs. The most common variety is known as lymphedema praecox, because it develops in adolescence. The condition is chronic and persists throughout life, usually becoming progressively more severe. In some families the condition runs through several generations, and it is then known as Milroy's disease. One of the striking features of chronic lymphedema of unknown etiology is its predilection for the female, at least 10 times as many women as men being affected. Another feature is that the lymphatics are not necessarily blocked.

Treatment is unsatisfactory. It is impracticable to confine otherwise healthy patients to bed; yet, while they remain ambulant, the disease shows an inexorable progression. In due course the disability becomes so severe that surgical maneuvers are resorted to in an attempt to diminish it. Excision of the deep fascia can be performed in order to encourage anastomosis between superficial and deep lymphatics. This operation is of little permanent value. It has now been largely abandoned in favor of excision of the affected skin and subcutaneous tissue, which is replaced by skin grafts. Various other surgical approaches have been made, but no method gives permanently satisfactory results. During recent years there have been reports about beneficial effects from cortisone or its analogues in chronic lymphedema. The authors used prednisone in treating 5 patients with lymphedema.

The results suggest that prednisone is not a treatment of general application in lymphedema. There is usually lessening of the edema (4 of 5 cases in the present series) when a full therapeutic dose is used, but the improvement is lost on reducing the prednisone to a level which would be safe for continuous maintenance treatment. Nevertheless, the authors regard the lessening of edema as of great theoretical interest. It seems improbable that there would be any such effect if the condition were due to purely mechanical factors; in other words, the abnormal limbs are in a dynamic state. Chronic lymphedema differs from other types of chronic edema in that the limb does not pit on pressure, but a similar nonpitting edema can occur in congestive heart failure if the condition persists long enough for fibrotic changes to supervene. Prednisone has been known to cause disappearance of the ascitic fluid, an effect which has been attributed to inhibition of aldosterone secretion. Similarly prednisone has been shown to reduce the edema of congestive heart failure. It seems important to look for evidence of a disturbance of water and electrolyte metabolism with special reference to hormonal influences. The effect of prednisone may possibly be due to the inhibitory effect that it has on the patient's adrenal glands.

The Natural History of Esophageal Varices: A Study **of 115 Cirrhotic Patients in Whom Varices Were Diagnosed Prior to Bleeding.** L. A. Baker, C. Smith and G. Lieberman. Am. J. Med. 26:228-237 (Feb.) 1959 [New York].

In 115 patients with cirrhosis of the liver, the diagnosis of esophageal varices was established, without a history of hemorrhage, by esophagoscopy performed at the Veterans Administration Hospital in Hines, Ill. The clinical course of these patients was uninterrupted by surgical intervention, and the patients were followed for intervals varying from 1 to 6 years and for an average of 3.3 years. Forty-one of the 115 patients were living and 74 were dead at the time the data were assembled. Bleeding from esophageal varices had occurred in 33 (28.6%). There were 20 (17.3%) who died of exsanguination, 31 (26%) who died of hepatic failure, and 23 (20%) whose deaths were due to unrelated causes. Eleven patients (9.5%) died of exsanguination during the first episode of bleeding. About 90% of the deaths from liver disease occurred within 2 years after varices were diagnosed.

Knowledge of these aspects of the natural course of the disease in such patients is necessary before it is possible to know what must be accomplished by *routine* prophylactic surgical shunt procedures, an admittedly radical form of prevention, in order to establish the validity of this surgical policy. Inasmuch as the essential difference in the objective of this policy, over the practice of reserving surgical intervention for those patients who have sustained a hemorrhage, is directed toward preventing death from the first hemorrhage, this becomes the most important datum in this study. It is estimated that by the time all 115 patients are dead, between 10 and 15% will have died of first hemorrhage. This, then, is the ultimate possible goal of achievement against which must be balanced the mortality rate, failures, and complications of routine prophylactic decompression surgery.

The unexpectedly long survival of some patients with esophagoscopically established varices, the relatively small proportion of suitable cases, the incidence of death due to causes other than hemorrhage from varices, and the substantial operative and preoperative risks indicate that at present routine prophylactic decompression surgery does not seem to offer any definite advantages to the patient. If further experience on a large scale reveals (1) criteria for determining those patients most likely to bleed, (2) that the over-all surgical mortality rate can be lowered to about 5%, (3) that surgical treatment prevents hemorrhages in nearly all patients over a period of years, or (4) if it is shown that there are serious remote untoward effects of hemorrhage on the course of the disease, this conclusion may well be unwarranted.

Pulmonic Stenosis with Intact Interventricular Septum. H. L. Gadboys, R. H. Kyle and R. P. Glover. Surg. Gynec. & Obst. 108:175-181 (Feb.) 1959 [Chicago].

Surgeons are coming to the point of deciding whether all cardiac surgery should be done by open-heart techniques, or whether certain intracardiac procedures will continue to be best done without the complexity of a direct visual approach. In pulmonic stenosis with intact interventricular septum the obstruction is generally valvular, and, unlike the indurated tissues of rheumatic valvular stenosis, the involved pulmonic valve tends to remain pliable for many years. Consistently excellent results should be attainable in these patients. During the past 7 years the authors operated on patients with valvular pulmonic stenosis with intact interventricular septum by a modified Brock transventricular valvotomy. A smaller group with intact septum required infundibular resection. There were in all 46 patients (19 males and 27 females), who ranged in age from 2 to 42 years, with an average age at operation of 13 years. Thirty-four patients were subjected to transventricular valvotomy only, 6 had infundibular resection, and 6 had both valvotomy and infundibular resection. The diagnosis in all but 3 patients was ascertained by catheterization.

There were no operative deaths in patients treated by closed valvotomy and/or infundibular resection. One patient with infundibular and valvular stenosis died 8 months after the operation was performed. The average peak systolic pressure gradient was 102 mm. Hg preoperatively. Operative pressure studies showed a drop from 97 to 44 mm. Hg for the series. Twenty-one patients were recatheterized, an average of 3½ years after the operation, and the gradient for the series has further decreased to 33 mm. Hg. The mean postoperative gradient for the patients with valvular stenosis alone was 28 mm. Hg. Clinical results were good to excellent in 86% of the patients.

The authors feel that in the rapidly progressing field of cardiac surgery there is little room for dogmatic statements about specific surgical methods. The possibility of overlooking an interventricular septal defect and the sometimes uncertain results with infundibular resection led them to elect direct visual methods for the correction of infundibular stenosis in any combination. They are not yet ready, however, to disown the simple, safe, Brock-type valvotomy as the treatment of choice for pure valvular pulmonic stenosis.

Biopsy of the Apex of the Axilla in Carcinoma of the Breast. C. D. Haagensen and S. J. Obeid. Ann. Surg. 140:149-161 (Feb.) 1959 [Philadelphia].

Over a period of 20 years the authors have made an effort to learn to select patients with carcinoma of the breast in whom the diseased tissue cannot be removed by the classical Halsted radical mastectomy. They found that their clinical criteria of operability were not strict enough. Impressed by Handley's observation of the frequency of occult metastases in the internal mammary nodes, and by Dahl-Iversen's finding of occult metastases in the supraclavicular nodes, they began to remove these lymph node groups as a preliminary biopsy procedure, for the purpose of ascertaining the presence of occult metastases at the periphery of the regional lymph node filter. They tested but finally abandoned biopsy dissection of the supraclavicular region, because they learned that the absence of metastases in this area does not preclude their presence in the nearby subclavicular nodes at the apex of the axilla. Their experience indicated that metastases in the apexes of axillary nodes, which constitute the final barrier in the axillary portion of the regional lymph node filter, mean incurability by radical mastectomy.

Biopsy of the apex of the axilla, which the authors substituted for supraclavicular biopsy in their triple biopsy procedure, removes the so-called subclavicular group of lymph nodes. In anatomic terms this means removal of the areolar and fatty tissue, together with the contained lymph nodes, from a small pyramidal area at the apex of the axilla. The cephalad plane of the pyramid is the axillary vein. Its dorsal plane is the chest wall in the vicinity of the first rib. Its ventral plane is the dense tough layer of the deep axillary fascia which spans the apex of the axilla beneath the pectoralis major muscle. The base of the pyramid faces laterally, and is defined by the thoracoacromial vessels. Its apex is the point at which the axillary vein passes beneath the tendon of the subclavius muscle and the clavicle. In terms of surface anatomy this pyramidal area lies just caudad to the middle third of the clavicle. The complete triple biopsy, which the authors employ as a preliminary operative procedure, consists at present of the 3 following steps: (1) biopsy of the primary tumor to establish the presence of carcinoma; (2) biopsy of tissues in the first, second, and third interspaces along the internal mammary lymphatic route; and (3) biopsy of tissues at the apex of the axilla along the axillary-supraclavicular lymphatic route.

Biopsy of the primary tumor is done through a 3-cm. or 4-cm. incision. A small wedge is excised for frozen section. The whole tumor is excised for biopsy only if it is less than 1 cm. in diameter. If carcinoma has been proved by frozen section, the biopsy wound is closed with a running suture. It is then sealed with a patch of rubber dam cemented in place with dermatone cement. This is important when another biopsy or mastectomy is to follow. Serum and blood containing carcinoma cells ooze from any biopsy wound unless it is sealed off in this way, and these cells may be implanted in another wound. The internal mammary biopsy is next performed. Instruments, drapes, gowns, and gloves are changed, and the skin is prepared anew, to avoid the possibility of transplanting carcinoma from the first biopsy wound to the second. For the third biopsy, that of the apex of the axilla, instruments, drapes, gowns, and gloves are again changed. Data obtained for the first 100 patients, on whom the described triple biopsy was performed, are tabulated, and illustrating case histories are presented. Indications for the performance of biopsy of the apex of the axilla are outlined on the basis of experience in the first 100 cases.

Hepatic Lobectomy. A. Brunschwig. Am. J. Surg. 97:148-150 (Feb.) 1959 [New York].

Of 75 patients undergoing excisional procedures on the liver for neoplasms of various types, 20 had a right hepatic lobectomy and 14 had a left hepatic lobectomy. Fourteen of the 20 patients had a simple right hepatic lobectomy, and 6 had a complex right hepatic lobectomy, i. e., right hepatic lobectomy and, in addition, partial pancreatoduodenectomy, or partial left hepatic lobectomy, or right colectomy. Of the 14 patients undergoing simple right hepatic lobectomy, 2 had massive angioma, 5 had primary hepatic malignant hepatoma, and 7 had metastatic carcinoma from previously resected primary lesions (6 in the colon and 1 in the uterus). Both patients with angioma were living and well 7 and 6 years after the lobectomy. Of the 5 patients with primary malignant hepatoma, 2 died after the operation, 1 lived for 2 years and died of recurrences, and 2 patients were living and well, each 6 years after the operation. Of the 7 patients with metastatic carcinoma, 3 died after the lobectomy, and the other 4 who lived up to 14 months obtained various degrees of palliation, mainly in the form of pain relief. All 6 patients undergoing complex right hepatic lobectomy had carcinoma of the gallbladder invading the porta hepatis and upper margin of the head of the pancreas; 5 of them died after the operation, and the 6th patient was living but had recurrences.

Of the 14 patients undergoing left hepatic lobectomy, 2 had a left hepatic lobectomy in conjunction with radical gastrectomy for cancer of the stomach. One of these lived for more than 17 years, and the other lived 1 year. In 2 patients left hepatic lobectomy was performed in conjunction with resection of gastric stumps and loops of jejunum for recurrent cancer of the stomach; both patients survived about 6 months. Eight patients underwent left hepatic lobectomy for metastases from cancer of the colon, uterus, and breast. There were 2 operative deaths, and survival varied from 6 to 23 months in 6 patients. One patient with carcinoma of the bile duct lived 18 months, and one with primary angiosarcoma was living and well 9 months after the lobectomy.

Malignant Lymphomas of the Gastrointestinal Tract. J. W. Grazer Jr. Surg. Gynec. & Obst. 108: 182-190 (Feb.) 1959 [Chicago].

This report is concerned with malignant lymphomas of the gastrointestinal tract seen at Duke Hospital, Durham, N. C., between 1930 and 1952. The record library lists were checked with the autopsy reports to include any localized lymphomas that were not diagnosed clinically. Each case history was evaluated, and surviving patients were asked to return for follow-up examination. If the patient failed to return, a questionnaire was sent to both the patient and the referring physician. All 31 patients whose records were found in the files were traced for evaluation of 5-year or longer follow-up results. The 31 patients included 8 with reticulum-cell sarcomas, 9 with lymphoblastic lymphosarcomas, 12 with lymphocytic lymphosarcomas, and 2 with mixed types. Patients with Hodgkin's disease or with giant follicular lymphoma localized to the gastrointestinal tract were not found in this group.

At its inception the lymphoma is located submucosally and may grow either as a polypoid mass or as a diffuse infiltrating lesion beneath the mucous membrane. The submucosal extension makes it very difficult for the surgeon to define the limits of the tumor. This explains the cases in which tumor tissue is found at the line of resection after supposedly adequate removal.

Eighteen of the 31 malignant lymphomas were in the stomach. The symptomatology was not characteristic, but an ulcer-like syndrome was seen frequently. Sixteen of the 18 patients had lost weight exceeding 10 lb. (4.5 kg.), 15 had epigastric burning pains or aches, and 11 had nausea and vomiting. A mass was palpated in 8, and 6 had had hematemesis or melena. In general, the over-all clinical appearance of these patients was much better than that of patients with carcinoma of the same extent. A palpable mass, while indicating a large tumor, does not preclude a cure, since 2 patients with large masses are still alive 6 and 26 years after resection. All 18 patients with gastric lesions underwent exploratory laparotomy. Resective surgery proved impossible in 7 of these patients. Nine subtotal resections were done with the hope of cure, and 2 additional patients had resections for palliation. Of the 9 patients on whom resection was performed for cure, 7 lived for more than 5 years. Two of the patients with "curative" resections died 7 months and 9 months after surgery despite radiation therapy, whereas in comparison the 2 with palliative resections survived 2 months and 2 years respectively. External radiation was the primary means of therapy in 6 of the 7 patients considered to have inoperable lesions. While 4 of the 6 obtained some palliation, all 6 were dead within 12 months. Nitrogen mustard was given to 2 patients with rapidly growing nonresectable lesions, but no real improvement was noted even though bone marrow depression indicated a good therapeutic level of the drug.

The duration of symptoms in the 11 patients in whom the malignant lymphoma was in the small intestine was considerably shorter than in the patients with gastric lymphomas. Only one patient had symptoms for as long as 2 years. The early symptoms consisted mainly of cramping epigastric and midabdominal pain associated with general malaise. The diagnosis was established only after abdominal exploration. One patient died within one month after an enteroenterostomy. Of the 10 patients who underwent resections, 3 lived 5 years or longer and are still alive from 6 to 22 years after operation. One elderly woman died 3 years and 4 months postoperatively of a coronary occlusion. The remaining 6 patients died within 2 years, 4 surviving for only 2 months after surgery. Five patients received roentgen-ray irradiation after surgery, but palliation of 6 to 8 months' duration was achieved in only 2. Four patients were given triethylene melamine (TEM) to slow their rapidly progressive disease. No beneficial effect was detected.

Two of the lymphomas were limited to the colon. Both patients presented themselves with symptoms of intestinal obstruction with a palpable mass. A 6-year-old boy died 2 months after a colectomy of the ascending colon was performed. A lesion of the transverse colon was seen in a 51-year-old man, and at operation the transverse colon was perforated. Despite a wide resection he succumbed with peritonitis. Surgical excision is the primary treatment in patients with malignant lymphoma of the gastrointestinal tract.

Liver Decompression by Drainage of the Common Bile Duct in Subacute and Chronic Jaundice: Report of Seventy-Three Cases with Hepatitis or Concomitant Biliary Duct Infection as Cause. A. A. Strauss, S. F. Strauss, A. H. Schwartz and others. Am. J. Surg. 97:137-140 (Feb.) 1959 [New York].

Surgical decompression of the common bile duct for relief of chronic jaundice resulting from acute and subacute hepatitis was performed on 73 patients. Of these, 31 had viral hepatitis, and 42 had subacute or chronic hepatitis due primarily to an infection of the common bile duct. A biliary fistula was formed by introducing a catheter into the hilus of the liver proximal to the atresia. For 1 or 2 days the fistula would yield only clear, watery fluid secreted from the ductal epithelium, showing that the liver cells could not function due to the increased intraductal pressure. When the pressure was relieved after 24 to 48 hours of decompression, the bile drained from the common bile duct assumed its normal color. All operations were performed with the aid of local anesthesia.

All patients with viral hepatitis had had jaundice for 9 weeks or longer and were in poor or critical condition; several were stuporous. Four of the 31 patients did not obtain relief of jaundice and died several months later. The other 27 patients completely recovered. Although these patients might have recovered without surgical drainage of the common bile duct, it is believed that the recovery rate in this series could not have been attained by medical therapy alone. All these patients had had an adequate trial period of medical treatment. In the group of 42 patients with an inflammatory process in the distal portion of the common bile duct and in the duodenal papilla, the ducts were thickened and infiltrated and contained a large amount of serous to seropurulent exudate. On probing the ducts, there was difficulty in passing through the papilla. Patients with this type of disease, as a rule, recover much more quickly from their jaundice and hepatitis than those who primarily have hepatitis. In some of the long-standing cases (3 to 6 months) the patients pass postoperatively into a phase of acute hepatitis that clinically resembles acute yellow atrophy of the liver. This happened in 2 of the 42 patients who died and in whom the autopsy finding was an acute necrosis of the liver with acute yellow atrophy. The other 40 patients recovered uneventfully.

GYNECOLOGY & OBSTETRICS

The Value of a Prepared Culture Medium in the Diagnosis of Trichomonas Vaginalis. W. H. Wolinska. Am. J. Obst. & Gynec. 77:306-308 (Feb.) 1959 [St. Louis].

The author employed 3 methods in searching for the presence of Trichomonas vaginalis in 203 consecutive patients from the special gynecologic service of the Strang Clinic at the Memorial Center for Cancer and Allied Diseases in New York. Fluid from the posterior vaginal fornix was obtained by means of two cotton-tipped applicators. One applicator was immersed in 1 cc. of warm isotonic sodium chloride solution for hanging-drop studies. The other applicator was immersed in 10 cc. of previously prepared culture medium. Routine cervical and vaginal smears on each patient were stained by the Papanicolaou method.

A trypticase culture medium was recently developed and is available as a prepared powdered medium known as Trichosel. It contains trypticase, cysteine hydrochloride, maltose, agar, methylene blue, and chloramphenicol. Twenty-three and six-tenths grams of this dehydrated material is dissolved in 950 cc. of distilled water, mixed thoroughly, heated, stirred, and boiled for about one minute. Nine and one-half cubic centimeters of the solution is dispensed into screw-top test tubes and autoclaved at 12-lb. pressure for about 15 minutes. Tubes are stored at room temperature. Just before it is used, 0.5 cc. of human serum, adjusted to pH 6, is added aseptically to each tube. Commercially available plasma, although having a pH of 7, may be used in lieu of serum. Cultures taken in the previously described manner do not require immediate incubation, but may be left at room temperature for several hours. Incubation overnight at 35 to 37 C is necessary to stimulate growth. The reading is done on wet smears in vitro. The recognition of Trichomonas organisms is based on the motility of the protozoa and the mobility of the undulating membrane. The presence of nonmotile organisms is not considered as a positive result. The highest number of motile parasites is usually found in cultures incubated 24 hours.

The other 2 methods, the hanging-drop technique and the cytological smear method, are also briefly outlined. Although these methods give a fairly accurate estimation of the presence of T. vaginalis, the Trichosel culture medium provides by far the most accurate method of detecting the presence of the parasite. The ease with which the vaginal secretion may be cultured under ordinary laboratory conditions renders this method eminently desirable for widespread use.

Transverse Vaginal Septum: Report of Three Cases with Method of Treatment. F. S. Rogers. M. Ann. District of Columbia 28:79-81 and 114 (Feb.) 1959 [Washington, D. C.].

Although there have been many reports about partial or complete absence of the vagina, the more common anomaly of transverse vaginal septum has received little notice. Clinically, transverse vaginal septum presents as a membrane of variable thickness, especially at its junction with the vaginal wall, where considerable fibrosis may be present. Openings are usually present in the septum and may be single or multiple, varying in size and location, but sufficient to allow for normal menstrual flow. The 3 patients presented here, ranging in age from 20 to 26 years, all had normal menses. One was married and complained of dyspareunia. All 3 patients were successfully treated by surgical excision and vaginal plastic procedure, but in each instance this was followed by the use of a vaginal dilator, designed to minimize scar formation and to prevent constriction of the operative area.

When excessive fibrosis is present, bleeding is difficult to control, proper approximation of the mucosal edges is often impossible, and there is the danger of cicatricial contracture. The author believes that the good therapeutic results obtained in the cases presented have been due in large measure to the proper use of the vaginal dilator postoperatively to prevent excessive scar formation and cicatricial contractures.

Diagnosis of Trichomonas Vaginalis Vaginitis. T. A. Burgh, C. W. Rees and L. Reardon. Am. J. Obst. & Gynec. 77:309-313 (Feb.) 1959 [St. Louis].

Studies were made on 1,848 female employees of the National Institutes of Health who participated in one or more of 3 annual vaginal cytology surveys. More detailed studies were made on 97 volunteers who were found to have trichomoniasis in the first survey or who were referred to the Trichomonas project because of vaginal discharge or itching. The patients were instructed not to douche or use vaginal medication for 24 to 48 hours before examination. The vaginal secretion for the Papanicolaou smear, wet smear, and culture was obtained by means of a glass pipette with a rubber bulb. For the Papanicolaou smear the secretion was expelled onto a glass slide, spread, and immersed immediately in equal parts of ether and absolute ethyl alcohol. The fixed smear was stained by Papanicolaou's method, and the slide examined. While the material for a wet smear is usually obtained by means of a cotton swab, in this study a small drop of vaginal secretion was expelled onto a dry glass slide (from the pipette used to make the Papanicolaou smear), a drop of isotonic sodium chloride solution added, and the preparation was then examined immediately for the presence of the characteristically motile trichomonads.

After these smears were prepared, the vaginal pipette was rinsed out in a tube of trypticase-liver-serum medium. The medium used in the culture studies was a combination of 2 nutrient fluids with the addition of horse serum, a reducing agent, and antibiotics. The composition of the culture medium is described, and the results obtained with it and the smear methods are compared. Diagnosis by means of the Papanicolaou smear was the least sensitive and specific method in that fewer than half of the patients from whom Trichomonas vaginalis was cultured were reported to have trichomoniasis. While the wet smear was the simplest, the culture method often demonstrated the infection when the wet smear was negative. The culture method was more convenient than the wet-smear method in that the microscopic examination did not have to be done immediately. It made little difference whether the patient had douched or recently used vaginal medication; if viable parasites were present, the culture method usually demonstrated them. Examination of vaginal cultures at 48 and 96 hours demonstrated nearly all cases of infection. About 8% of such cultures from infected women were negative, however. A single negative examination, therefore, should not rule out trichomoniasis in a woman with appropriate clinical findings.

The following procedure is recommended for the diagnosis of vaginal trichomoniasis: 1. Obtain a sample of vaginal secretion by means of either a cotton-tipped applicator or a vaginal pipette. 2. Inoculate the secretion into a tube of culture medium by inserting the applicator into the tube or rinsing out the pipette in the medium. 3. Add sodium thioglycollate and antibiotics. 4. Incubate the culture at 37 C and examine a drop of sediment for motile organisms with the compound microscope, preferably at 24-hour intervals but at least at 48 and 96 hours. 5. If a preliminary examination is desired when symptoms are acute, the material in the cotton-tipped applicator can be removed from the culture tube and used to prepare a wet smear. In a similar manner, a wet smear can be prepared from the pipette at the time of inoculation.

PEDIATRICS

Sex Reversal in Newborn Babies. K. L. Moore. Lancet 1:217-219 (Jan. 31) 1959 [London].

Sex reversal may be detected in the newborn infant by the sex-chromatin test. Oral smears were collected over a period of 12 months from 3,715 babies (1,911 males and 1,804 females) born at the Winnipeg General Hospital. The oral mucosa of the infants was scraped with a sterile nickel spatula, and the material deposited on a slide. Each smear was fixed immediately in equal parts of ether and 95% ethyl alcohol, the fixation extending overnight. The smears were stained with cresylecht violet. They were examined under the oil-immersion objective of a binocular microscope for the presence or absence of visible sex chromatin. The anatomic sex of the infant was unknown to the microscopist at the time of the examination. Infants with a chromosomal sex opposite to their anatomic sex were given a special examination.

All except 5 of the infants had a chromosomal sex consistent with their anatomic sex. The 5 exceptions were all anatomic males; they were normal-appearing infants but had sex-chromatin patterns typical of chromosomal females. The proportion of nuclei counted exhibiting female-sex chromatin ranged from 53 to 64%. These chromatin-positive males are regarded as exemplifying female-to-male sex reversal. The results of this investigation indicate that female-to-male sex reversal is commoner than male-to-female sex reversal, for no sex-reversed males were detected among the 1,804 anatomic females tested.

In commenting on the probable future development of chromatin-positive newborn males, the author mentions the possibility of testicular dysgenesis, of sterility or fertility, and of the possibility of the hereditary transmission of the chromatin-positive male characteristic. He suggests that the 5 chromatin-positive males in the present series will probably show normal sex development until puberty. Some will probably develop characteristics of testicular dysgenesis during adolescence, some may also become mentally abnormal, but others may become normal-appearing fertile males. The etiology of female-to-male sex reversal is also discussed. While early deficiency of primordial germ-cells in the gonads has been suggested as a causative factor for sex reversal in patients with testicular dysgenesis, the author suggests other possibilities, particularly the possible role of hormonal imbalance.

Aldrich's Syndrome (Thrombocytopenia, Eczema, and Infection in Infants): Studies of the Defense Mechanisms. W. Krivit and R. A. Good. A.M.A. J. Dis. Child. 97:137-153 (Feb.) 1959 [Chicago].

The authors report on 7 male infants, between the ages of 3 and 22 months, with Aldrich's syndrome, clinically manifested by rectal bleeding, petechiae, eczema, suppurative otitis, infections consisting of bronchopneumonia or abscess, and an abnormally depressed platelet count. In 4 of the 7 patients a positive familial history was obtained, which fulfilled the requirements for a sex-linked recessive trait by which the syndrome appears to be transmitted. The typical onset of melena in the neonatal period was noted in 5 of the 7 children. Persistent thrombocytopenia and normal numbers and morphology of megakaryocytes were observed. Peripheral end-marrow eosinophilia was noted. The examinations of the bone marrow revealed a mild plasmacytosis and toxic changes among the neutrophils, but no other abnormalities. Nonspecific inflammatory changes were noted in the skin and lymph-node biopsy specimens. Autopsy in one patient and lymph-node biopsy in another revealed multiple thromboses of small arterioles. All the patients died despite cortisone and corticotropin therapy followed by splenectomy in one patient and despite multiple types of antiallergic therapy in the others.

Because of the frequency and severity of infections noted, an investigation of the defense mechanisms was made. This revealed no clear evidence of deficiency of the immune response to most antigens. The isoagglutinins were regularly absent in these patients. Gamma-globulin levels were normal or slightly elevated. Properdin levels were normal. Leukocyte function in the inflammatory reaction, migration, and phagocytosis were within normal limits. The causation of the thrombocytopenia was studied. No platelet agglutinins were noted. Normal production of platelets was apparent. The thrombocytopenia did not show any relation to the course of the eczema. A study of adrenal function revealed the presence of normal circulating plasma 17-hydroxycorticosteroids. Also, the response of 17-hydroxycorticosteroid levels to stimulation with corticotropin was normal. All attempts at treatment of the disease remained unsuccessful, though both adrenal steroid therapy and systemic treatment with estrogen and progesterone ameliorated the eczematoid processes.

Purpura Fulminans. S. E. Crawford and J. G. Riddler. A. M. A. J. Dis. Child. 97:198-201 (Feb.) 1959 [Chicago].

The authors report a 9-year-old girl who was admitted to the Jackson-Madison County General Hospital in Jackson, Tenn., because of purpura and ecchymotic areas over the lower extremities. Four hours after admission the patient went into severe hemorrhagic shock. Therapy consisted of intravenous administration of levarterenol bitartrate, whole blood, and hydrocortisone sodium succinate, in addition to massive doses of crystalline penicillin. Fifteen hundred cubic centimeters of whole blood was given slowly during the next 24 hours, and the patient's condition improved. On the second hospital day the bleeding time was 6 minutes, the platelet count was 40,000 per cubic millimeter, and the hemoglobin level was 15 Gm. per 100 cc. Three days later the bleeding time became normal; the platelet count reached 480,000, and after another 3 days it was 507,000. The skin of the lower extremities showed no advance of ecchymosis 12 hours after the institution of hydrocortisone therapy but these areas showed early slough and blister formation on the second hospital day. On the 14th hospital day the patient showed partial-thickness loss of skin over large areas of the left thigh, legs, and dorsum of the feet. A portion of all the toes of the right foot showed dry gangrene of the distal and inferior portions. There were scattered areas of full-thickness skin loss on the left thigh and the legs. The left leg and foot showed large areas of skin loss with dry gangrene of the distal half of the lateral 3 toes. The toes were allowed to heal and slough without excision. Complete healing of all the lesions had occurred 7 weeks after the onset of illness. The prompt and dramatic response of purpura fulminans in this patient far outweighs the very real danger of the use of adrenal cortical hormone in the presence of active infection. Survival in this usually fatal condition depends on early diagnosis and prompt adequate therapy.

Familial Addison's Disease: Case Reports of Two Sisters with Corticoid Deficiency Unassociated with Hypoaldosteronism. T. H. Shepard, B. H. Landing and D. G. Mason. A. M. A. J. Dis. Child. 97:154-162 (Feb.) 1959 [Chicago].

The authors report on 2 sisters in whom during their second year of life hyperpigmentation, weakness, and later convulsions occurred. One of the 2 patients died at the age of 30 months, and autopsy was performed. The clinical course of the other patient with a diagnosis of adrenal cortical hypofunction (Addison's disease), who is living, was followed from the age of 3 years to that of almost 5 years. Both patients were abnormally tall. The autopsy findings in the older sister corresponded closely with what would be expected in the younger sister according to clinical studies. These children did not have the classical form of Addison's disease in that the electrolyte-regulating mechanism of the adrenal cortex was functioning; aldosterone production was normal, although corticoid production was inadequate. In the younger patient, the serum protein-bound iodine level was slightly elevated. Neither of the 2 patients had any symptoms or signs suggesting secondary hypothyroidism.

In the patient who died, both the right and the left adrenal glands were difficult to identify on autopsy. Sections of the adrenal glands showed marked atrophy of cortical tissue. Only occasional clumps of cortical cells remained in the zona glomerulosa. All cells of the zona fasciculata and zona reticularis were absent. Autopsy also revealed the presence of the anterior pituitary in which the chief microscopic finding consisted of marked decrease of both basophil and acidophil cells. There was no evidence of any hypothalamic damage, either on autopsy in this patient or on clinical grounds in the other. The pituitary of the patient who died appeared to be responding to the state of adrenal insufficiency, suggesting that the initial endocrine defect lay in the adrenal glands rather than in the hypophysis; this concept was supported by the observation of the selective damage of the zona fasciculata and zona reticularis of the adrenal glands, perhaps due to a genetically determined metabolic disorder or to common exposure to an infectious or toxic agent. An alternative explanation is that the patients reported on shared a familial defect in anterior pituitary function, which resulted in a specific inability of the anterior pituitary basophil cells to secrete corticotropin (ACTH). The presence of mineral-corticoid activity in the absence of other corticoid activity is an unusual finding in patients with adrenal cortical hypofunction.

Bronchogenic Cysts in Infants and Children. J. W. Herrmann, T. C. Jewett Jr. and G. Galletti. J. Thoracic Surg. 37:242-250 (Feb.) 1959. [St. Louis].

Seven boys and 5 girls with congenital bronchogenic cysts were operated on in the surgical department of the Children's Hospital in Buffalo, N. Y. Of these 12 patients, 4, between the ages of 1 day and 2 months, had expanding pulmonary cysts and were admitted as either acute or subacute respiratory emergencies. All 4 patients had a history of rapid and progressive cyanosis and dyspnea. The pertinent physical findings were hyperresonance, decreased breath sounds, and evidence of mediastinal shift as noted by the position of the apical heart beat. Chest roentgenograms revealed single or multiple well-circumscribed, thin-walled cystic structures which were occupying part or all of one hemithorax. The cysts partially or completely compressed the adjacent lung parenchyma. Other confirmatory signs which indicated the expanding nature of the cyst were depression of the hemidiaphragm and widening of the interspaces on the involved side. Two of the 4 patients had lobectomies and one had a pneumonectomy, with uneventful postoperative courses. The 4th infant underwent laparotomy because of an erroneous roentgenologic diagnosis of diaphragmatic hernia; the patient died suddenly before thoracotomy could be performed. Pathological examination of the resected specimens revealed single or multiple cysts lying within the lung parenchyma with surrounding atelectasis. On cross section, they had a smooth, pale, glistening surface with a glary type of mucus on the wall. Some were crossed by fine trabeculae, whereas others were multiloculated. A bronchial communication was usually demonstrable. Inflammation was not prominent.

The remaining 8 patients, between the ages of 6 months and 9 years, had secondarily infected pulmonary cysts occurring as a result of bacterial invasion of a previously sterile cyst. These children had a classical clinical history of intermittent respiratory infections with asymptomatic intervals. The first attacks were usually interpreted as bronchitis or pneumonia. After several such attacks, chest roentgenograms established the correct diagnosis. The commonest symptoms and signs in these patients during the acute stage of their disease were those of pulmonary suppuration, namely, fever, dyspnea, cough, and purulent sputum. The roentgenographic picture of the secondarily infected cysts differed from that of the expanding cysts in that there was little evidence of compression of surrounding structures. The cysts appeared extremely round, smoothly outlined, and thin-walled with varying degrees of pneumonitis and frequent evidence of fluid levels. Three of the 8 children underwent pneumonectomy, 4 underwent lobectomy, and 1 had marsupialization and subsequent thoracoplasty performed. One patient who had several attacks of cardiac arrest during pneumonectomy died shortly after the operation, and another patient died on the operating table during right middle lobectomy. Both deaths were attributable to massive flooding of the contralateral lung by infected material from the cysts, and would be preventable today by proper preoperative preparation with antibiotics, postural drainage, and bronchoscopy. Pathological examination of the surgical specimens revealed a definite predilection for these cysts to occupy the lower lobes. Their gross appearance was similar to that of the expanding cysts, but infection supplanted the signs of compression of neighboring pulmonary tissue. On cross section, the bronchial-type mucosa had a glistening appearance. The cavity itself usually contained purulent exudate, and there was evidence of pneumonitis in the surrounding parenchyma.

Congenital pulmonary cysts may be divided into 2 major groups based on either of 2 presenting symptom complexes associated with expansion or infection. Expanding pulmonary cysts are usually found in newborn infants; since they may run a rapidly fulminating course, prompt diagnosis and surgical intervention are mandatory. Infected pulmonary cysts occur in older children and usually require a more protracted period for accurate diagnosis and adequate preoperative preparation. The treatment of choice in both types of congenital pulmonary cysts is by resection of the involved pulmonary parenchyma.

Rubella and Incidence of Congenital Abnormalities. V. P. Coffey and W. J. Jessop. Irish J. M. Sc. 6:1-11 (Jan.) 1959 [Dublin].

The authors present a survey of the outcome of pregnancies in mothers who either contracted or were in contact with rubella during the Dublin epidemic in 1956. Seventy-five patients who had been attending the antenatal outpatient departments of the 3 Dublin maternity hospitals and St.

Kevin's Hospital, Dublin, were found to have had contact with rubella or had had rubella. The condition of the babies at birth was noted, and 3 months after birth they were examined again in an effort to detect congenital abnormalities, such as lesions of the cardiovascular system or deafness, which would not have been obvious at birth. Forty-nine of the 75 patients had only had contacts. Five of the 75 patients gave birth to infants with congenital abnormalities, giving a rate of 67 per 1,000 as compared with 16 per 1,000 in a previous survey conducted in Dublin maternity hospitals between 1953 and 1954, when rubella was not epidemic. Infected mothers had a higher percentage of congenitally deformed children than had those who were only contacts of the disease. Mothers who contracted the infection during the first trimester of pregnancy had a higher percentage of congenitally deformed children than had those who contracted rubella during the last 6 months. There was no such trend in the incidence of congenital abnormalities among infants born to mothers who were exposed to rubella but did not contract the disease.

Gamma globulin had been given to 2 mothers who had contact with rubella within the first 2 months of pregnancy, and both had normal babies. No relationship could be found between incidence and sex of the baby in either infected or exposed mothers. As regards weight of the babies at delivery, a higher proportion of the children of mothers who actually had the disease were below normal weight at birth than were those of mothers who were only contacts of the infection. It is suggested that girls be encouraged to become contacts of rubella with a view to contracting the disease before marriage, that the pregnant woman who has not had rubella avoid contact with the infection during pregnancy, and that, if such a woman becomes a contact, the development of the infection be prevented by administration of immune serum or gamma globulin.

On the Use of Cortisone Preparations in Hemolytic Disease of Newborn Infants Due to Isoimmunization in the ABO System (Effect of Cortisone Preparations on Bilirubinemia). G. Murano and E. Barbagallo. Pediatria 66:889-901 (Nov.-Dec.) 1958 (In Italian) [Naples].

Two newborn infants with hemolytic disease due to maternal immunization were treated with cortisone preparations. The values of bilirubin in blood taken 12 hours after birth were 14.4 mg. per 100 cc. in the first child and 13.5 mg. per 100 cc. in the second. The first child was given 20 mg. of prednisone per day for 10 days and 5 mg. per day for the following 10 days. A marked improvement in its general condition was already present by the 12th day of treatment when the concentration of bilirubin had dropped to 3.8 mg. per 100 cc. Seven months later the infant was seen again and was found to be in good general condition. There were no clinical signs of encephalic involvement, and development had been normal. The second child was given 15 mg. of prednisone per day for the first 10 days and 5 mg. per day for the following 10 days. The general condition of the infant had improved markedly by the 10th day of treatment, the concentration of bilirubin having dropped to 3.2 mg. per 100 cc. When the child was seen again after 7 months, it was found to be in good general condition, and its development had been normal. The prednisone therapy had had a good effect, especially on the indirect bilirubin values in both children. The authors believe that cortisone preparations not only check the hemolytic disorder but also stimulate the enzymatic activity of the liver.

The Natural Clinical History of Choreo-Athetoid "Cerebral Palsy." P. E. Polani. Guy's Hosp. Rep. 108:32-45 (no. 1) 1959 [London].

An attempt was made to obtain a clearer clinical picture of the sequence of neurological events in choreoathetoid cerebral palsy, a form of cerebral palsy characterized by the presence of athetosis, chorea, or a mixture of these 2 conditions with unwanted movements that are more difficult to define and describe. Seventy-three children (39 girls and 34 boys) with this form of the disease were studied. Fifty-five of the children were first seen before the age of 5 years, 29 before the age of 1½ years, and all 73 before the age of 10 years. When last seen, 52 were more or less ambulant, and 21 were nonambulant. All patients had unwanted movements which in most of the patients were present at rest; in the remainder these movements appeared only in response to an attempt to move or in association with emotional tension. In 6 patients some muscle groups showed spastic hypertonia. Intermittent hypertonia was present in 14 patients. The tone appeared normal in 8 patients when they were fully relaxed, and in an additional 8 the tone was thought to be decreased. The remaining 37 patients had definite hypotonia when they were fully relaxed. Twelve of the 73 patients had paralysis of voluntary upward conjugate eye movements, and 28 had severe but not total loss of hearing.

Etiologically the 73 patients were subdivided into 3 groups. Twenty-two had a history of severe neonatal jaundice due to Rh isoimmunization, 16 had had severe neonatal jaundice without evidence of blood group incompatibility between mother and infant, and the remaining 35 patients had no history of severe neonatal jaundice, but a history of various complications of delivery and neonatal condition. A history of disturbance of pregnancy, such as toxemia or nontoxic separation of the placenta, was elicited in 2 of the 16 patients in the second group. The incidence of prematurity was highest in the second group in whom jaundice had been found without evidence of blood group isoimmunization. In the third group without jaundice, one-third were premature, one-quarter were born through breech delivery, and three-quarters had clinical asphyxia in the perinatal period. The patients in the first group with kernicterus due to immunization had the most stormy neonatal period, with twitching and opisthotonos. All the patients without neonatal jaundice had a history of sucking or swallowing difficulty from the start, and a substantial number of these patients had neonatal fits, cyanotic attacks, and frequent vomiting.

The neonatal symptoms in the 73 patients had commonly disappeared by the end of the second week of life, so that between the ages of 2 weeks and the end of the first or second month of life there was generally a silent period except for common difficulty in feeding and respiratory stridor. After the second month of life the presence of a neurological disturbance became evident in 9 out of 10 patients, and nearly all showed delayed development to a greater or less extent. Thirty-seven patients had opisthotonic attacks, 25 had hypertonia, and 3 had striking hypotonia. At the end of the first year 23 had marked hypotonia. Of 56 patients in whom the onset of unwanted movements could be reasonably accurately timed, these appeared before the age of 2½ years in 39 and between 3 and 3½ years in the remaining 17.

These data show that in about 50% of the patients with this type of cerebral palsy there is a strong link with a clear-cut causative factor (severe neonatal jaundice), while in the other 50% interference with normal oxygenation in the perinatal period seems to be causatively involved. It appears that much more prospective work by individual observers is necessary if the clinical problems posed by the natural history of the various forms of cerebral palsy are to be solved. Preferably, the clinical examination should be conducted before obtaining a history.

Acute Gastro-Enteritis in Infants and Young Children with Special Reference to Some Etiological Factors (Analysis of 665 Cases). S. S. Manchanda and N. N. Arora. Indian J. Pediat. 25:599-607 (Nov.) 1958 (In English) [Calcutta].

Of 4,438 children admitted to the department of pediatrics of a hospital in Amritsar, India, between July, 1955, and December, 1957, 665 (450 boys and 215 girls) had acute gastroenteritis. This high incidence of acute gastroenteritis (15%) is not surprising with the present low state of sanitation and ignorance about food hygiene in the province of the Punjab. Five hundred fifteen (77.4%) of the 665 children were between the ages of 1 and 12 months, 113 were between the ages of 13 and 48 months, and 37 were over 48 months of age. Of the 665 children, 109 (16.4%) died; 79 of these were less than one year old. Three hundred ninety-seven (59.7%) of the 665 children were admitted during the summer months (May, June, and July), as compared with only 268 children admitted during the remaining 9 months. There was a mortality rate of 21.3% among the bottle-fed infants, as compared with a mortality rate of 9.18% among the breast-fed infants.

Although breast feeding is not unpopular in the Punjab, breast feeding is supplemented by bottle feeding in 70 to 75% of the infants, buffalo milk diluted with water and modified with various aromatics often being used. The early introduction of a milk rich in fat caused diarrhea. Poor housing conditions and the lack of proper lavatory arrangements also contributed to the occurrence of gastroenteritis. Eighty-four strains of various bacteria were isolated from 60 diarrheal stools studied bacteriologically. In most of the cases several pathogenic organisms were isolated from the culture of the fecal specimens. Serologic types of Escherichia coli were isolated from 30% of the total specimens, Paracolobactrum organisms from 31.6%, Staphylococcus pyogenes var. aureus from 21.6%, Streptococcus faecalis from 21%, Proteus organisms from 20%, Pseudomonas aeruginosa from 13.3%, and Shigella flexneri from 1.2%.

The causation of diarrhea among these Indian children thus involved several environmental factors, such as feeding, atmospheric humidity, seasonal incidence, social status, and food hygiene; in many instances a bacterial pathogenic agent was recognizable. The highest incidence was observed among bottle-fed infants during summer. Other gram-negative bacilli and gram-positive cocci than the serologic types of Esch. coli seem to be important in the causation of gastroenteritis.

Diagnostic Value of the Determination of Serum Aldolase in Epidemic Hepatitis in Children. M. Leonescu, N. Cajal, V. Boeru and others. Ruman. M. Rev. 2:44-47 (July-Sept.) 1958 (In English) [Bucharest, Romania].

Aldolase levels were determined in the serums obtained from 61 children, between the ages of 16 months and 10 years, admitted with epidemic hepatitis to a children's hospital for infectious diseases in Romania in 1956 and 1957. Jaundice was present in 38 patients and was absent in 23. Serum aldolase values were determined also in 25 normal persons, in 33 patients with miscellaneous noninfectious diseases, in 7 adult contacts of children with epidemic hepatitis, in 2 children with measles, and in 4 children with epidemic parotitis. The adolase activity in normal persons varied from 4 to 20.3 units and averaged 9.7 units. The aldolase activity in the patients with noninfectious diseases averaged 12.1 units. The mean values of aldolase were 19.4 units in the children with measles and 24.5 units in those with epidemic parotitis. In the adult contacts of children with epidemic hepatitis, the mean aldolase value was 18.3 units.

In the 38 children with epidemic hepatitis associated with jaundice, the average serum aldolase values were 75.4 units during the first week, 46.8 units during the second week, 32.6 units during the third week, and 17 units during the fourth week. The average aldolase values in the 23 children with epidemic hepatitis not associated with icterus were 85.3 units during the first week, 41.1 units during the second week, 23.7 units during the third week, and 20.1 units during the fourth week. The over-all average value of the 23 determinations of serum aldolase in these patients was 52.1 units.

None of the patients with positive results from dysproteinemia tests had normal serum aldolase values. There were 5 children with increased serum aldolase values who had normal results from dysproteinemia tests and who had no bile pigments in the urine. The urobilinogen test revealed normal values in 4 of these 5 patients and slightly increased values in 1. The diagnosis of epidemic hepatitis in these 5 patients was made on the basis of epidemiologic and clinical features and was confirmed by the increased serum aldolase level. The maximum value of serum aldolase found in the determinations made in the 61 children with epidemic hepatitis was 146.1 units, i. e., almost 15 times the normal value, but an increase in aldolase level to 2 to 8 times its normal value (as determined by other workers) is to be considered as a pathological increase. Discrepancies in results may, in fact, be due to the different techniques employed.

According to most workers the serum aldolase level reaches its peak during the first week of the disease, with a subsequent decrease during convalescence. Though nonspecific, the increase in the serum aldolase level is a far more reliable laboratory aid in the diagnosis of epidemic hepatitis than the dysproteinemia tests. The results obtained in the children with nonicteric epidemic hepatitis justify the use of the determination of the serum aldolase level on a larger scale in the diagnosis and differential diagnosis of nonicteric epidemic hepatitis. The study of the serum aldolase level in contacts of patients with epidemic hepatitis may be of aid in the diagnosis of subclinical infections, thus acquiring a prophylactic and epidemiologic value as well.

Scrofula Caused by Atypical Mycobacteria. J. S. Chapman and L. R. Guy. Pediatrics 23:323-331 (Feb.) 1959 [Springfield, Ill.].

Several recent reports on human infection by atypical mycobacteria referred to disease of cervical lymph nodes in young children. The authors present the histories of 6 children with scrofula caused by atypical mycobacteria. The children ranged in age from 20 months to 5 years. The lymph nodes removed for biopsy or aspirated pus were inoculated into various mediums. Colonies were exposed to various lights, were subcultured, and were tested for drug susceptibility, with the neutral red test, and for catalase production. All strains were injected into the groins of guinea pigs and intravenously into rabbits. In addition to the studies of lymph node tissue or pus from scrofulous children, swabs were made from the tonsillar crypts or pharynges of 43 apparently healthy children referred to the clinic for Mantoux tests. The organisms removed from the enlarged nodes or from aspirated pus differed considerably among themselves, were clearly distinguishable from Mycobacterium tuberculosis, but resembled, or were identical with, those recovered from swabs of tonsils or pharynges of healthy children. It is not possible to regard all these organisms as belonging to the same strain; they belonged to the general group of chromogenic mycobacteria.

A summarization of the histories of the 6 children provides several points of clinical differentiation from true tuberculous scrofula. These children did not originate from tuberculous families, as shown by roentgenologic examination of the parents and the negative Mantoux tests of the siblings. The infected children themselves had weak or negative reactions to tuberculin. The enlarged nodes were not associated with mediastinal adenopathy, bronchial obstruction, disease of bone, or other lesions. The onset of the infection was usually rapid and was sometimes associated with rather high fever, perhaps resulting from pharyngitis. The cervical nodes underwent rapid enlargement and early suppuration. The disease remained localized to the submandibular group, as opposed to scrofula caused by Myco. tuberculosis of the human type; the latter involves several groups of lymph nodes, progresses slowly, produces comparatively less enlargement and much less suppuration of nodes, is associated with contacts, and is nearly always an incidental finding in the course of a progressive primary infection with marked tuberculin sensitivity. This disease seems to be due to invasion by chance of the deeper structures by oropharyngeal contaminants, perhaps preceded by ordinary infections in the oropharynx. No evidence points to person-to-person transmission.

Maple Syrup Disease: Isolation and Identification of Organic Acids in the Urine. J. H. Menkes. Pediatrics 23:348-353 (Feb.) 1959 [Springfield, Ill.]
